As no deleterious effects have been shown to arise from intravenous glucose with insulin in true diabetic coma, and it is a valuable safeguard against hypoglycaemia for those whose laboratory facilities are meagre, and for other reasons mentioned, we advise its use along with other methods of treatment in these cases. In those cases of severe acidosis, which many insist on calling coma, we agree that the administration of glucose intravenously is seldom necessary.—I am, etc.,

Department of Medicine, University  
of Toronto, Jan. 18th.

WALTER R. CAMPBELL.

## TREATMENT OF CANCER BY RADIUM.

SIR,—In your issue of January 28th (p. 159) Dr. W. Fletcher Shaw, continuing his correspondence with relation to the treatment of cancer by radium, says that "neither London nor Manchester give any information about the work they are doing."

As Medical Superintendent of the Radium Institute of London I feel it incumbent upon me strongly to refute that statement. The London Radium Institute opened its doors for the treatment of patients in July, 1911. In April, 1913, a report dealing with the work of the Institute from July, 1911, to December, 1912, was published, with particulars of cases, methods of treatment, and statistical tables. A report on similar lines was issued each year until 1924.

In 1925, in compliance with the request of many medical practitioners, *A Clinical Index of Radium Therapy*, based upon and compiled from the actual work of the Radium Institute, was published. This was followed, in 1926, by *A Manual of Technique in Radium Therapy*, and, in 1927, by *Superficial Radium Therapy*. A work on *Deep Radium*

*Therapy* is in active preparation, and will be issued in a few months' time.

All the publications of the Radium Institute have been supplied post free to any medical practitioner who cares to apply for them, and this fact has been clearly stated in the advertisements in the leading medical journals.

Papers by various members of the staff of the Radium Institute have appeared in the *British Medical Journal* and *Lancet* from time to time, and I would venture to direct Dr. W. Fletcher Shaw's attention to the fact that in the issue of the *British Medical Journal* of January 28th, in which his letter appears, there are two papers by my colleagues: "Inoperable sarcomata treated with radium," by Dr. Roy Ward, and "The combined action of colloidal lead and radiation on tumours," by Dr. J. C. Mottram.—I am, etc.,

A. E. HAYWARD PINCH,  
Medical Superintendent.

The Radium Institute, London, W.1,  
Jan. 28th.

SIR,—The numerous communications which have appeared recently on this subject indicate a growing recognition of the importance of radium in the treatment of cancer. There is in these communications one point on which there is a striking unanimity—namely, the desire for reliable long-period statistics in this country. In view of the experience of certain clinics, and the efforts now being made along their lines by others, it is fortunate that under the auspices of the British Empire Cancer Campaign Fund an International Convention on Cancer Research is to be held in London in July, on which occasion the interchange of views on this and allied problems should be profitable. Those interested in radium work would do well to avail themselves of this special opportunity.—We are, etc.,

ARTHUR B. SMITH, M.B., F.R.C.S.Ed.  
SYDNEY M. SMITH, M.B., Ch.B.Ed.

London, W.1, Jan. 27th.

## FATALITY RATES OF SMALL-POX.

SIR,—As your other correspondents have not replied to all Dr. L. A. Parry's questions (January 21st, p. 116), although I had no wish to write further on this subject, it has been urged upon me that a reply should be made, and I therefore trust that your readers will pardon the tedious reiteration of some facts which are well known to many of them.

In regard to Dr. Parry's question (2), there is, to start with, a confusion between percentages of "people vaccinated" in the community and infants being vaccinated in certain years. As a rough estimate we may assume that from 1854 to the first exemption Act in 1898 about 85 per cent. of infants were being vaccinated, that the rate then declined at a uniform speed to 75 per cent. in 1908, when exemption became easier, and then fell at a more rapid rate to 38 per cent. in 1921. By referring back each age group of the census populations to the respective years of birth, and multiplying by the percentage of infants being vaccinated at that time, we obtain the following approximate percentages of all people living at various dates who had been vaccinated in infancy:

1871 ...	... 40 per cent.	1911 ...	... 74 per cent.
1881 ...	... 50 "	1921 ...	... 74 "
1891 ...	... 60 "	1926 ...	... 66 "
1901 ...	... 70 "		

It would, therefore, be as fair to ask, "Why did the total deaths from small-pox in England and Wales decrease from 23,062 in 1871, when only 40 per cent. of the population were vaccinated, to 5 in 1921, when 75 per cent. were vaccinated?" As a matter of fact, the reasoning either way is fallacious, for on the same basis of estimation it appears that the percentage of the population under 20 years of age who had been vaccinated did not change appreciably from 1871 to 1901, though the deaths at those ages fell from 14,223 to 127. The truth is, of course, that arguments of this kind can prove little or nothing, since epidemics come and go according to laws which we do not yet understand, and which involve many factors other than vaccination. Moreover, it is forgotten by those who

use this kind of argument that never at any time since vaccination was introduced have there been in this country less than seven or eight million persons unvaccinated, and, therefore, as a *wholesale* preventive measure vaccination has not yet been seriously tried.

Turning to Dr. Parry's question (4), I presume that his figure of 80 per cent. is derived from the totals for 1926, in which year there were 5 cases admitted to the M.A.B. hospital, of which 4 (all adults) had been vaccinated at some time. In the three preceding years 19 out of 29 cases admitted had a record of vaccination—about 65 per cent. No sound conclusion can, of course, be drawn from such minute samples from the population of London, but I think that if Dr. Parry were to look at the ages of these "vaccinated" patients he would find what is, perhaps, a more satisfactory answer, for most of them were over 30. From the calculation just referred to it appears that more than 80 per cent. of the population over the age of 30 at the present time must have been vaccinated in infancy, apart from many who were vaccinated in the army, so that 80 or more is the percentage of vaccination to expect at present in any large sample of adults at these ages.

Dr. Parry's questions (3) and (5) are simply the old arguments of the antivaccinationists served up in a new form—for example, the old question, "Why were there less cases and a lower fatality rate in Leicester in 1891-92 than in Sheffield in 1887-88, in spite of the much lower vaccination rate in Leicester than Sheffield?" It would be equally reasonable to ask why there was an influenza death rate of 1.6 in Leicester in the first great epidemic wave of influenza in 1918 as compared with an influenza death rate of 11.6 in Sheffield in the second great wave of 1918, although undoubtedly more people were attacked in the first than the second. The answer is, that the second epidemic took *everywhere* a more fatal form than the first, and we have got to leave it at that, not deluding ourselves that it is an explanation, but merely a statement of fact. The same kind of answer covers most of these small-pox conundrums, as both Dr. Millard and Professor Greenwood have indicated in their letters. In 1919 Germany, in common with most of Eastern Europe, was swept by a great epidemic of variola major which England almost escaped; since 1921, however, we have become increasingly affected by the milder form which seems to have come to us from America; at any rate, there were 139,107 cases in the United States of America in 1907-12, with a fatality of less than 1 per cent.

The only *conclusive* proof of the efficacy of vaccination must consist in comparing the vaccinated with the unvaccinated at the same ages in the same town and during the same epidemic. Where this has been done in epidemics of variola major with large enough numbers the results have been definite enough to satisfy most minds as to its efficacy. In addition, there is a mass of presumptive evidence, relating to both types, such as is furnished by the age distributions reproduced in my letter of January 21st.—I am, etc.,

University College, London, Jan. 27th.

PERCY STOCKS.

#### FOREIGN BODIES IN THE STOMACH.

Sir,—An interesting account of successful manipulation by Dr. Gilbert Scott of a key in the stomach (January 28th, p. 133) has unfortunately been broadcast in the daily press. I am sure nobody will regret this move than will Dr. Scott himself, for the impression will be conveyed to the lay mind that manipulation of *all* foreign bodies through the pylorus ought to be undertaken by the radiologist, and no more dangerous suggestion could possibly be made. The knowledge common to all radiologists of the wisdom of leaving most foreign bodies to be dealt with by nature is unquestionable. Imagine the horrible possibilities if an attempt were made to try and manipulate an open safety pin, for instance, or a dental plate, with the knowledge that most of these foreign bodies will be passed through the pylorus without any assistance on the part of the radiologist. If I needed any convincing upon this point, Dr. Scott has himself supplied it in his comment upon the

impossibility of trying to manipulate the round label attached to the key. How often has one not had to wait for some days for a coin of the size of a halfpenny to pass; indeed, the only foreign body which nature appears to find difficulty in dealing with is the rounded flattened body.—I am, etc.,

London, W., Jan. 29th.

STANLEY MELVILLE.

\*\* Dr. Gilbert Scott was, of course, in no way responsible for the publicity given to his note by the daily newspapers. We regret that the columns of a professional journal should be used in this manner, week after week, by our contemporaries of the lay press.

#### DRAINING THE SEPTIC UTERUS.

Sir,—I was pleased to notice in your issue of January 21st (p. 117) the favourable criticism of Dr. David Watson on the intrauterine injection of glycerin for the promotion of drainage in septic conditions. The reason for my employing pure undiluted glycerin without the use of antiseptics is the result of years of experience. I am sure everyone has noticed that after the use of a hot intrauterine douche symptoms and signs of septic absorption are apt to follow, and entire cessation of the discharge, either pus or blood.

Intrauterine treatment with glycerin is certainly the best treatment for post-partum haemorrhage, and has superseded the hot intrauterine douche. It acts as a powerful stimulus to the uterus, and as much as 120 c.cm., or more, may be injected. The hot douche coagulates the tissues and prevents tissue drainage. I have noticed on many occasions the same symptoms have been produced by the application of strong antiseptics to the interior of the uterus. With regard to the use of even mild antiseptics, the results seem to be just as good without them. Glycerin has been used extensively in this hospital for the last nine years, during which time we have given over 30,000 intrauterine treatments. Patients have received as many as fifty treatments, and sometimes four injections in the twenty-four hours.

I might add that in cases of femoral thrombosis the patients are treated as usual, but on a special obstetric bed, and the legs are held apart in trough-like splints. In cases of pyelitis and cystitis the uterus is treated as well, also in pneumonia and influenza occurring in the puerperium when there are signs of secondary haemorrhage, etc. During the whole of the time we have had not a single death arising from the injection of glycerin, and not a single case of haemoglobinuria or albuminuria. Rather than any toxic effect, the patients say they feel better. But one should issue a word of warning: in the case of the small nulliparous uterus, a large injection, given hastily, may be followed by abdominal pain and faintness. In cases following labour or miscarriage the uterus is relatively insensitive, and large quantities can be given without producing pain, if injected slowly.—I am, etc.,

A. REMINGTON HOBBS,

St. Mary Abbots Hospital,  
Kensington, Jan. 21st.

Consulting Gynaecologist to the Royal  
Borough of Kensington.

#### EARLY RHEUMATIC MYOCARDITIS.

Sir,—In accounts of early rheumatic myocarditis I am surprised to find no mention of what I have learnt in the last few years to regard as the earliest symptoms. This is the history from the mother, of the child, after apparently enjoying play, coming in and "flopping" in a chair in a completely tired-out manner. This is noticeable in a child who has not done so as a rule, and is frequently the cause of advice being sought. It leads one to inquire about the slight pains which, years ago, the mothers would have called "growing" pains. The cardiac dullness may be already suspiciously larger than the average and the apex beat displaced; but even if these signs are not present, if the child is allowed to continue up and about for a week or two they are fairly sure to develop. A systolic murmur comes considerably later. Bed, with blankets, and salicylates and alkalis for a few days in these earliest cases

work wonders, and the mother is willing to carry out this treatment and interrupt school life when the risk of permanent heart trouble is pointed out.—I am, etc.,

LORTUS E. WIGHAM, M.B.Cantab.

London, E.4, Jan. 18th.

### FOREIGN BODIES IN THE ABDOMEN.

SIR,—I read with interest the account of the second case described by Dr. H. Roland Segar on p. 96 of your issue of January 21st, because it affords a human parallel with an animal experiment performed by the late Professor Paul Heger at the Solvay Institute, Brussels, about twenty years ago, and described by him to me in 1925. He was working on the functions of the omentum and similar structures in the abdomen, and related how in one case a foreign body introduced into the abdominal cavity was carried to the root of the omentum, excluded from the abdominal cavity by the folding over and adhesion of the omentum, and finally made its way through the wall of the intestine and was passed per rectum.

I believe the specimen is still at the Solvay Institute, although I cannot be sure.—I am, etc.,

KENNETH J. FRANKLIN, D.M.

The Pharmacological Laboratory,  
Oxford, Jan. 26th.

### THE PHYSIOLOGY OF DEFÆCATION.

SIR,—As a physiologist I have been following the correspondence on the physiology of defæcation with much interest, and I am glad to see that at last one of your correspondents, Dr. E. R. Barton, refers to the height of the seats of closets as one of the causes of constipation.

It would seem that we are never going to get a change in the construction of these seats, which appear to become higher and higher as each new hotel, club, train, or steamer is built. It is not only that they are far too high, but they are invariably level, whereas they ought to slope backwards or downwards in order to permit of the assumption of the natural squatting position, the physiology of which is so well understood.

That such a physiologically correct seat has been made I know for certain, for the makers of it were good enough to send me an illustration of it many years ago, and this I showed to my class each session. If I had it beside me I should send it for editorial comment, but it is not available, and I forget the name of the makers. I hope, however, that if they see this communication they will make it known that a physiologically correct type of closet has been on the market.

There is really no valid reason why the absurdly high and level type of seat should continue to be made; the explanation is the physiological momentum of those who continue to construct something not adequately adapted to its uses. There are many analogies. One is the large jug or pitcher which is provided with so small a spout that this cannot possibly permit a sufficient outflow of fluid. The makers, of course, have forgotten what a spout is for, and are now treating it merely as an ornament.—I am, etc.,

D. F. FRASER-HARRIS.

The Authors' Club, London, S.W.1, Jan. 18th.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

DR. F. A. DIXEY, F.R.S., late Wills Medical Fellow, Bursar, and Sub-Warden of Wadham, and formerly demonstrator of physiology in the University, has been elected to an Emeritus Fellowship at Wadham College.

### UNIVERSITY OF CAMBRIDGE.

At a congregation held on January 27th the following medical degrees were conferred:

M.B., B.Ch.—W. F. Cooper, E. S. Bolton.  
M.B.—W. G. S. Hopkirk.

The Nita King Research Scholarship for the encouragement of original research in the etiology, pathology, and prevention of fevers has been awarded to Mr. Leonard R. Jones, M.A., of Emmanuel.

### UNIVERSITY OF LONDON.

MR. M. E. DELAFIELD, M.C., M.B., B.Ch.Camb., has been appointed to the University Chair of Chemistry as applied to Hygiene tenable at the London School of Hygiene and Tropical Medicine.

Dr. E. L. Konneway has been awarded the William Julius Mickle Fellowship for 1928 (value £275) in respect of the work carried out by him on cancer research during the past five years.

Mr. H. L. Enson, C.B., M.S., has been reappointed to represent the University on the General Medical Council.

Dr. Andrew Balfour, C.B., will be the representative of the University at the Congress of the Royal Sanitary Institute to be held in Plymouth in July next.

### UNIVERSITY OF LIVERPOOL.

Mrs. ADAMI, the widow of Dr. J. G. Adami, Vice-Chancellor of the University, who died in 1926, has presented the sum of £100 for the endowment of a prize in the department of pathology.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A QUARTERLY committee of the Royal College of Physicians was held on January 26th, with the President, Sir John Rose Bradford, in the chair.

#### Membership.

The following candidates were admitted to the membership:

Roland George Anderson, M.B.Lond., Godfrey William Bamber, M.B.Camb., Donald Campbell, J.A.H.Dub., Clement Clapton Chesterman, O.B.E., M.D.Lond., Ronald Cove-Smith, M.B.Camb., William Hefmoyr Craib, M.B.Camb., Sheldon Francis Dudley, O.B.E., M.D.Lond., Surgeon Commander R.N., William Norwood East, M.D.Lond., Abd el Kader Elmi-El-Shukbasi, L.R.C.P., William Evans, M.D.Lond., John Rex Goddall, M.B.Sydney, Cecil Noel, M.B.C., Mark Adam, Bristol, Ronald Arthur Phillips, L.R.C.P., John Douglas Procter, L.R.C.P., Reginald Hans Taylor Rea, L.R.C.P., Abd el-Azim Yousif Mostafa, Salama, L.R.C.P., Sydney Watson-Smith, M.D. Edin., Howard Hilton Stewart, M.D. Belfast, Charles Cady Ungley, M.D. Durham, Marion Boyd Wenliss, M.B.Melb., Lawrence Stuart Woolf, L.R.C.P.

#### Licences.

Licences were granted to the following 120 candidates who had passed the necessary examinations of the Conjoint Board and conformed to the by-laws and regulations of the College:

R. Anderson, G. D. Augenlicht, L. Bernard, F. G. Booker, G. N. Box, M. S. R. Broadbent, J. W. Bromley, C. E. S. Bullen, Eleanor M. Carless, A. M. Chandhuri, S. S. Chesser, T. L. Cleave, G. A. Coggin, C. N. Cohen, C. C. Cookson, N. Cox, P.era R. C. Crawford, W. S. Greer, D. S. Davies, E. R. L. Davies, Helena M. De Hartog, M. M. Day, Olivia F. Digby-Smith, H. Doyle, M. R. Doyle, C. B. Drew, John S. C. Elkington, Alexander G. H. Enslin, A. G. Ensor, H. Epstein, M. M. Fikri, J. Foster, H. D. F. Fraser, Mabel O. G. Kingston, T. R. Gaha, P. J. Ganner, Caeridia P. Giles, E. M. Goitein, R. A. P. Gray, C. R. Greene, C. S. Gros, Bridget S. P. Gunsey, B. Haring, R. M. J. Harper, J. Harris, R. L. Harward, N. V. Haslam, J. O. Hatrick, J. Hennell, Margaret A. L. Herberson, Anna M. Hilliard, E. A. H. Hindhaugh, N. M. Modivala, Josephine M. Howells, W. H. Hubert, W. L. Hurn, A. L. Hyatt, Dorothy M. James, D. C. K. R. Jenkins, J. J. Jones, R. T. Jones, H. Kaitz, A. R. Kerridge, A. K. M. Khan, P. Kuhne, T. E. Lameche, B. A. Lamprell, W. J. Lloyd, Margaret I. Macecock, A. A. Miles, Mary M. Moller, C. F. Moore, C. S. Morgan, W. H. Myburgh, J. J. O'Donoghue, Lois J. Ogle, E. N. O'Neill, Ella M. Oswald, T. N. Parish, W. E. C. Parry, P. I. Peltz, P. Perles, C. D. Politeyan, A. E. Porritt, Monica M. M. Power, J. C. Preston, Agnes M. Ramsbotham, W. G. Richards, J. H. Riemond, T. McK. Robb, F. E. Roberts, Elizabeth J. Robinson, Florence E. Robinson, R. S. Rudland, Margaret M. Russell, R. W. Saboung, W. J. M. Sadler, H. A. Seidenberg, Doris G. Sharville, D. G. Shield, C. S. Skidmore, T. E. Skinner, W. D. Steel, G. Steinberg, W. P. R. Swenmer, H. A. Taylor, Dorothy Tims, Ruth M. W. Turner, D. R. Tweedie, G. P. A. van Rossum, J. A. Vernon, Elizabeth H. Waller, H. S. Waters, K. H. Watkins, I. Waynik, C. H. C. White, H. O. White, Hannah E. Wilby, E. A. Wood, N. R. W. Wynne-Williams.

\* Under the Medical Act, 1876.

#### Diplomas in Special Subjects.

Diplomas in the subjects indicated were granted jointly with the Royal College of Surgeons to the following:

D.P.H.—F. Asker, A. D. Bellios, F. J. Benjamin, W. A. Brown, Isabella M. G. Butler, Dorothy M. Catchpool, N. E. Chadwick, Nancy M. Coutts, Angel V. B. Crawford, N. N. Curnow, Gweneth M. Daniel, Hilda C. Dean, E. L. F. De Mel, Kathleen Dickinson, Christabel S. Eyre, Nancy K. Gibbs, Gladys Goument, W. H. Hamilton, R. S. Johnson, M. H. Khan, P. E. R. Lahorde, E. R. Lewis, K. L. Malhantra, H. L. Malhotra, Ethel W. Morris, G. Napier, H. A. Pargeter, B. L. Patney, K. P. Pillai, T. A. Seekings, S. R. A. Shah, Kathleen Shelton, C. H. C. Toussaint, S. N. Vastil, P. L. Whig, C. A. Wood.

PSYCHOLOGICAL MEDICINE.—W. A. Caldwell, L. C. Cook, I. Frost, N. G. Harris, E. J. C. Hewitt, R. G. B. Marsh, N. R. Phillips, R. P. Rees, H. H. Steadman.

OPHTHALMO MEDICINE AND SURGERY.—H. K. Basu, J. C. Brangan, A. E. F. Chaffer, E. J. Collins, S. Dayal, G. I. Evans, B. F. Eminson, E. R. Jagger, M. S. Katre, B. K. B. Khare, L. R. Lalvani, G. D. Malhotra, M. A. Mithalva, D. G. Patwardhan, W. J. B. Riddell, Louie A. Rubidge, D. D. S. Stewart, C. R. Verling-Brown.

ENTOMOLOGY AND OTOLOGY.—H. Bahgat, R. E. Buckingham, H. S. Chhabhi, H. A. Cowan, S. Dayal, E. M. Dearn, H. G. Downer, R. A. Highmore, Barbara M. Logan, P. MacMurray, J. H. O'Donnell, A. MacK. Ross, S. S. Sen, J. J. Stander, P. Subbaramaya, H. L. Valdia.

## Appointments.

Dr. A. R. Russell was elected to the Council in the place of the late Sir Percy Bassett-Smith. Dr. Moulton Copeman was appointed to represent the College at the 39th Congress of the Royal Sanitary Institute. Sir Leonard Rogers was appointed as delegate to the centenary celebration of the Faculty of Medicine, Cairo, in response to the invitation of the Minister of Education of the Kingdom of Egypt.

## Reports.

Communications were received from the President of the University of Toronto and from Dr. R. D. Rudolph with reference to the recent celebration of the centenary of King's College, Toronto. A report was received from the representative of the College on the General Medical Council. Dr. C. O. Hawthorne reported on the Departmental Committee of the Optical Practitioners (Registration) Bill. Books and other donations to the library presented during the last quarter were received and thanks were accorded to the donors. The annual report of the Examiners for the Licence on the examination held in the year 1927 was received.

## SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

SURGERY.—G. N. Fox, A. W. Lassowsky, J. R. Mitchell.  
 MEDICINE.—G. N. Fox, D. I. Jones.  
 FORENSIC MEDICINE.—G. N. Beeston, B. P. Jones, D. I. Jones, A. W. Lassowsky, J. R. Mitchell.  
 MIDWIFERY.—W. B. Halliwell, H. T. Ince, E. A. Johnstone, H. D. K. Wright.

The diploma of the Society has been granted to Messrs. D. I. Jones and A. W. Lassowsky.

## Obituary.

## JOHANNES FIBIGER, M.D.,

Professor of Pathology, University of Copenhagen.

WITH profound sorrow we have to record the death of Johannes Fibiger, professor of pathology in the University of Copenhagen. Professor Fibiger was in his sixtieth year, and had lately undergone a serious operation. Whatever be the triumphs the future holds for cancer research, his name and his work will always have an honoured place, for he was the pioneer of the experimental inquiry into the causation of cancer.

While the study of malignant diseases remained for the most part a matter of observation and conjecture little or no progress could be made in our knowledge of their etiology. Theories and ingenious hypotheses led us no further to the heart of the problem. No one had produced cancer experimentally. His was the first successful attempt, and his claims were at once recognized and welcomed by authorities throughout the world. It is a matter of pride to us to remember that within a few days of the publication of his preliminary communication before the war the *BRITISH MEDICAL JOURNAL* emphasized the importance of this first successful direct attack on the central problem. When the story was fully unfolded no one could withhold admiration for the brilliant manner in which he developed his research from a simple chance observation, and the dogged perseverance which enabled him to overcome almost insuperable difficulties. Appreciations of this work, as it developed, have appeared from time to time in these columns, and only a brief summary need now be given.

In the course of some experiments in tuberculosis, a subject on which he had gained more than a national reputation as an investigator, Professor Fibiger noticed that three rats in one batch had tumours of the stomach. Knowing that this was a rarity, if not an unheard-of occurrence, he attempted, though without success, to transmit these tumours by transplantation and feeding experiments, and by putting fresh rats into the cages previously occupied by the infected animals. Prolonged investigation of hundreds of serial sections of the tumours, which proved to be squamous epitheliomata, revealed to his observant eye minute structures which enabled him to reconstruct the picture of an undescribed nematode threading its way through the superficial layers of the epithelium. Careful dissection of a preserved tumour afterwards provided him with a complete specimen of this worm, to which he gave the name *Spiroptera neoplastica*. Convinced that the occurrence of this parasite in all three tumours was more

than an accident, he set himself to discover the origin of the spiroptera, but the only information he could elicit from extensive reading of the literature about nematodes was that Galeb, many years previously, had found nematodes in the stomachs of rats that had been fed on the common cockroach (*Periplaneta orientalis*). This clue was pursued, though the nematodes described by Galeb were of a different species, and Fibiger examined the bodies of many rats in a district of Copenhagen where the cockroaches abounded, and he fed his laboratory rats on these cockroaches, but in no case did he find parasites in the stomachs, nor was there ever any trace of new growths. But he did not lose heart. He found out that in a large sugar factory in Copenhagen there were numbers of rats and swarms of cockroaches of a large and unusual type—the *Periplaneta americana*—which had come from the West Indies with the consignments of sugar. Several of these rats were caught and killed, and when they were examined they were found to have gastric tumours, and in the tumours the *Spiroptera neoplastica* was found. His perseverance deserved its reward. He collected some of the cockroaches and fed his laboratory rats on them, and demonstrated that the cancers were always associated with the spiropterae. Investigation showed him that these cockroaches contained in their muscles the larval stage of a worm which, when the cockroach was eaten by the rat, developed into the adult spiroptera in the gastric mucosa of the rat. The worm in some way stimulated the gastric epithelium to excessive proliferation of an invasive type, and when the mature stage of the parasite was attained the eggs were evacuated with the faeces. This in turn was eaten by the cockroaches, and so the cycle was carried on. Having thus succeeded in infesting the rats, and being uncertain of his supply of American cockroaches, he endeavoured to infest the ordinary type of cockroach from the eggs evacuated from the rat, and in this he was fortunately successful, for the sugar refinery was burned to the ground and his supply of American cockroaches ceased. The experiments, as the research went on, showed clearly that he could produce gastric cancer in the rats at will, that the epitheliomata produced were preceded by more benign proliferations, that there was a minimum period required before the spiroptera produced their effects, that metastases were formed without the presence of parasites, that the age of the animals was of no importance in respect of results, that wild rats and other rodents were immune to the action of the worms, that mice were relatively insusceptible and that the production of gastric cancer in them was exceedingly slow in comparison with rats, that the spiroptera could lodge in and produce epithelioma of the tongue, that other parts of the intestinal tract were resistant to the action of the parasites, and numerous other observations. In short, he demonstrated that cancer could be caused by chronic irritation of peculiar types—in this case some toxic secretion from a parasite; but it was perfectly obvious that this cancer-producing agent could not be invoked to account for any cancer except the gastric cancer of these rats. There must be other causes operating in other cases.

Inspired by his work, Yamagiwa and Ichikawa in Japan took up again the attempts to produce cancer by prolonged applications of coal tar, and showed us once more that patience was the necessary requisite for success. Their experiments were welcomed by Fibiger, who introduced them to the Western world and extended them, and furnished investigators the world over with a ready means of inducing cancer and studying its early phenomena. Others have carried on the work in other lines, but all will agree that to Fibiger is due the honour of blazing the trail.

A. L.

## WILLIAM BRITAIN MORTON, M.D.,

Medical Superintendent, Wonford House, Exeter.

DR. WILLIAM BRITAIN MORTON, medical superintendent of Wonford House, Exeter, died on January 10th, aged 60. He was educated at University College Hospital, London, took the diplomas of the England Conjoint Board in 1890, and graduated M.B.Lond. two years later, proceeding to

the M.D. in 1896. After serving as assistant medical officer of the County Asylum, Lancaster, he was appointed in 1892 as assistant medical officer at Wonford House, Exeter, where he remained till 1897, when he became physician to Brislington House, near Bristol. After holding that post for twelve years, he returned to Wonford House, Exeter, as medical superintendent. He was a member of the Royal Medico-Psychological Association and of the Exeter Division of the British Medical Association. He is survived by his widow, a daughter, and one son, Dr. E. F. Morton, who practises at Topsham.

We are indebted to Mr. RUSSELL COOMER, F.R.C.S., of Exeter, for the following personal appreciation of Dr. Morton: I happen to have been a member of the committee of management of Wonford House during the whole period of Dr. Morton's time there as superintendent, and thus knew him and his work well. Not physically strong, he was unable to take much part in outside affairs, but he devoted himself wholeheartedly and unfeignedly to the interests of the institution he served. His great knowledge of his specialty was combined with a most kindly and sympathetic attitude to our patients, and he was obviously beloved by all who were capable of such appreciation. As a committee we soon realized that we had a highly satisfactory officer, and his eighteen years of service were marked by most cordial relations and by complete trust on our part; conditions which were never, even on a single occasion, disturbed throughout the whole of that period. There is no question that, quite apart from our appreciation of him in his official capacity, he was a man loved by every member of the committee. His wife was a lady of most artistic temperament. Her aunt married Sir Sidney Colvin and her sister Sir Charles Holroyd. She possessed a delightful soprano voice, well trained during her early years in Italy, and this enabled her to give great help in the musical entertainments provided for the patients. We deplore the loss of Dr. Morton deeply, and feel that his place will be most difficult for us to fill.

#### THE LATE MR. BASIL LANG.

We have received a number of personal tributes to the work and character of Mr. Basil Lang, supplementing the obituary notice printed in our last issue.

Colonel L. T. Nash, C.M.G., R.A.M.C.(ret.), who commanded No. 8 General Hospital, writes: Mr. Basil Lang joined me at Woolwich in August, 1914, as one of my staff, mobilizing with No. 8 General Hospital. We went over to France on August 14th, and were stationed on the heights over Rouen in a large building, where the hospital remained during the whole of the war. We had a most strenuous time getting the equipment, etc., into this building, as we had to work with the French authorities, and transport was almost impossible to procure. Mr. Lang was simply invaluable to me during this time, for he, as indeed did all my staff, worked day and night; but his knowledge of French, which he spoke fluently, made his assistance of exceptional value. As soon as we got settled in I put him in charge of the x-ray apparatus, and in a few days he reported that the one we had was not up to date. He told me that he had taken it to pieces, and that if I would give him a few days' leave and the money he would go to Paris and procure what he required to make the outfit efficient. When he returned he set to and made a splendid apparatus, and produced plates which could not be excelled, so much so that cases later on were sent from various hospitals to be radiographed by him. The x-ray department was, I considered, a model one, and I do not believe that any other hospital in France at that time had a similar one. This was solely due to the efforts of Mr. Lang, and the fact that later on, after I had left the hospital, he was specially selected to take a mobile x-ray apparatus around the front lines shows what a reputation he had gained for himself and his work. He also produced some wonderful photographs in colours of frostbite and other surgical cases which were considered invaluable. During the time he served under me he was always ready to give his help in every emergency, always cheery and bright. He did the ophthalmic work of the hospital as well as the x-ray, and altogether was, I consider, an invaluable officer.

Dr. E. A. ALDRIDGE, M.C., late Brevet Major R.A.M.C., who knew Mr. Basil Lang as a boy, recalls memories of him as an enthusiastic private in the Cambridge University Rifle Corps

when they met again in camp at Cosham. My next impression of Basil (he writes) was from dear old Sister "Eyes" at Bart's. She spoke so highly and enthusiastically of him, not only of his ophthalmic work, but of his originality in anything mechanical, and I myself have thought that his inventive and mechanical turn of mind might have had wider scope in the scientific and engineering world than in ophthalmics. . . . While serving on the Western Front as M.O. I often heard of him as he moved along the line accompanied by his x-ray, etc., plant. It was a great regret to many of us that in the bestowal of war honours he did not receive the recognition which we felt he deserved, but the greater reward was surely his in the consciousness of having done his best in the R.A.M.C. I will not touch upon the increasingly useful and active work that Basil Lang did since the war, for that is well known to the profession. The heartfelt sympathy of all his former Moorfields assistants will go out to their much revered master in the loss of an only son of such high talent, whose death in the prime of life is not only a loss to his friends, but also to the ophthalmic world.

Mr. M. ATKINSON-ADAM writes: Basil Lang used often to discuss with me scientific progress and the many problems coming before him in connexion therewith but only indirectly involved in his professional work. He took a great interest in engineering and electrical and chemical science. Indeed, I have often been surprised at the unexpected, and usually very accurate, knowledge he displayed in the difficult borderlands between those branches of science. His mind gave the impression of great ingenuity, and he was always devising fresh methods, and scheming new devices for carrying them into effect, in whatever field his energies were directed for the time being. His death is indeed a great loss, not only to his profession, but to his friends in many branches of scientific work.

Dr. GEORGE EDWARD KINNERSLY of Guernsey died on January 13th, aged 53. The son of Mr. William T. Kinnersly of Bracknell, Berks, he received his medical education at St. Thomas's Hospital. He took the diplomas of the English Conjoint Board in 1894, and served for some years as resident medical officer at the French Hospital, Shaftesbury Avenue. In 1901 he was appointed Constable of St. Peter Port, Guernsey, and in the following year was elected Jurat of the Royal Court; at the time of his death he was Senior Jurat on the bench and Lieutenant-bailiff of the island. For his services in the great war, when he served as captain in the R.A.M.C. in England, Malta, and Guernsey, he received the honour of M.B.E. Dr. Kinnersly is survived by his widow and five sons.

### The Services.

#### HONORARY PHYSICIAN TO THE KING.

BREVEY COLONEL W. R. P. GOODWIN, D.S.O., R.A.M.C., has been appointed Honorary Physician to the King, in succession to Major-General S. F. St. D. Green, C.B., C.B.E., late R.A.M.C., who has retired.

#### HONORARY SURGEONS TO THE KING.

HIS MAJESTY has approved the appointment of Colonel R. W. Knox, D.S.O., I.M.S., and Colonel C. Hudson, C.B., C.I.E., D.S.O., I.M.S., as Honorary Surgeons to the King, in succession to Colonel E. L. Perry, D.S.O., I.M.S., and Colonel A. N. Fleming, D.S.O., I.M.S.

#### ARMY DENTAL CORPS.

THE KING has approved the appointment of Lieut.-General Sir John Goodwin, K.C.B., C.M.G., D.S.O., F.R.C.S., formerly Director-General, Army Medical Service, as Colonel Commandant of the Army Dental Corps. Sir John Goodwin, it will be remembered, is now Governor-General of Queensland.

#### NAVAL MEDICAL COMPASSIONATE FUND.

THE quarterly meeting of the directors of the Naval Medical Compassionate Fund was held on January 24th, when Surgeon Vice-Admiral Arthur Gaskell, Medical Director-General of the Navy, took the chair, and the sum of £115 was distributed among the several applicants.

**Medico-Legal.****CONVICTION OF A "MEDICAL ELECTRICIAN."**

THE ancient rule of our criminal law that a man who, in committing a felony, causes the death of a human being is guilty of the capital offence of murder obtains no favour with a modern jury. Proof of this was afforded by the trial at the Old Bailey last week of Charles Jackson Palmer, who had been committed on charges of murder and manslaughter of a young married woman named Goldsmith, three months pregnant, whose death in Palmer's consulting room followed an attempt to procure abortion.

In the past the abortionist was invariably charged with murder and sentenced to death in our criminal courts, as witness the words of Mr. Justice Hawkins in passing sentence of death in *R. v. Calmore*, reported in the *Times* of August 9th, 1881: "That the offence amounts to wilful murder is the law as it at present stands, and as in all human probability it will exist in time to come." Juries, however, became unwilling to convict on the capital charge, and the Crown, towards the end of last century, ceased endeavouring to obtain a conviction for murder in cases of abortion, relying on the manslaughter charge instead.

Here the Crown reverted to the old rule in charging Palmer with murder, but the Grand Jury threw out the bill, and the trial proceeded on the lesser charge of manslaughter. Despite the brilliant forensic efforts of the defending counsel, Mr. Norman Birkett, K.C., the petty jury found the prisoner guilty upon evidence which the Lord Chief Justice described as so clear as to be quite overwhelming—"it approached the certainty of mathematical demonstration."

The verdict of guilty meant that the jury accepted the evidence of two pathologists, Sir Bernard Spilsbury and Dr. H. B. Weir—whose *post-mortem* examination revealed an abrasion which suggested the use of a syringe and the presence of soapy water recently injected—and that they did not accept the defence that the young woman died of shock from the passing of alternating currents through the body at a low voltage and for an innocent purpose.

The defendant denied all knowledge of the fact that his patient was pregnant. Possessing no medical qualifications, he conducted a practice as a medical electrician, licensed by the London County Council, at Upper Brook Street, giving treatment for muscular weakness and nervous debility. He said that Mrs. Goldsmith visited his consulting room five times for electrical treatment for nervous debility, and it was during the last of these visits that she died. The Lord Chief Justice's questions to an electrical engineer called to give evidence for the prosecution elicited the comparatively harmless nature of the apparatus found in the defendant's consulting room. It was similar to what is in use in hospitals, and the amount of current of which it was capable was limited to 80 volts—quite insufficient, in his opinion, to cause a serious burn or shock. This evidence the jury accepted, notwithstanding the testimony of an electrical engineer called for the defence, who said he himself could not withstand the intensity of the full current obtainable from the apparatus. The discovery made at the *post-mortem* examination was met by a complete denial—that the defendant did not give the vaginal injection of soap and water, and that this must have been done by the deceased herself, or by some third party, before she came to his consulting room. Dr. F. J. Browne, professor of obstetric medicine in the University of London, who, on the defendant's behalf, attended the *post-mortem* examination, expressed the opinion that death did not follow immediately on the injection, as his microscope revealed indications that a miscarriage had been going on a few hours. Professor Browne thought it possible that the woman could have made the injection herself, and agreed with the possibility of death from shock from electricity at low pressure. This was the strongest evidence produced by the defence, but it did not explain why, if the deceased or some third party gave the injection elsewhere, she went immediately to Palmer for further electrical treatment for debility. It is not unusual for medical men to find themselves ranged on different sides in a court of law, with the inevitable comments by counsel. "The jury," said Mr. Birkett, "in dealing with the medical evidence were in a region where an eminent man said one thing and an eminent man on the other side said 'I say to the contrary.' Both were honest men and both were

distinguished men. One said this and one said that." In law, if there is a reasonable doubt in the minds of the jury the defendant is entitled to the benefit of it, and an acquittal should follow. The Lord Chief Justice, in the final words of his summing up, said to the jury that "they might think it right to ask themselves the question whether the true conclusion was not, as it well might be on this evidence, that the case for the prosecution had been established in every vital particular." The jury, after an absence of an hour and twenty-five minutes, brought in a verdict of guilty.

After the verdict there came the police disclosure that for months past the defendant's premises had been visited frequently by the authorities because of suspicions that the practice of medical electricity was largely a cloak for running a profitable business as an abortionist.

The Lord Chief Justice, in passing sentence on Palmer, said: "The officer who gave his evidence so fairly concerning you mentioned on Friday certain suspicions that you had for some time past been carrying on the trade of abortion. I shall deliberately put out of my mind suspicions and rumours of suspicions. It is right that I should direct my attention to the evidence, and to the evidence in this case alone. That evidence convinces me that you were carrying on the trade of abortion. It was as a person carrying on that trade that you were consulted by Mrs. Goldsmith. It was as a person carrying on that trade that you treated her. Such persons undoubtedly subject their patients or clients to very grave risks, and it is right that all of them, wherever they may be in this country, should understand that they incur grave risks themselves. The law must have regard to human life, even though the particular life in the individual case may not be of the highest consequence. In the public interest it is necessary that you should go to penal servitude for seven years and pay the costs of the prosecution."

**Medical News.**

As already announced a special meeting of the council of the Charity Organization Society will be held at Doulson House, 296, Vauxhall Bridge Road, S.W.1, on Monday, February 13th, when there will be a discussion on the voluntary hospitals and the public authorities. The speakers will be Sir William H. Hamer, Dr. E. Graham Little, M.P., and Dr. Humphrey Nockolds. The chair will be taken by Lord Dawson of Penn at 5.30 p.m.

At the Mansion House meeting at 3 p.m., on February 8th, in aid of the extension fund for the General Lying-in Hospital, Lord Dawson will take the place of Sir Berkeley Moynihan, who is unable to attend. The other speakers will include Lord Birkenhead and Mrs. Stanley Baldwin.

THE Fellowship of Medicine announces that Dr. R. M. Stewart will lecture on secondary forms of mental deficiency at the Medical Society, 11, Chandos Street, on February 6th, at 5 p.m. On the same day, but at 2.30 p.m., Mr. J. P. Lockhart-Mumery will give a clinical demonstration at St. Mark's Hospital. On February 10th there will be two clinical demonstrations; the first, on diseases of children, will be given by Dr. G. A. Sutherland, from 2 to 3 p.m., at the Paddington Green Children's Hospital, and the second, on cataract, will be given at 5 p.m. at the Royal Westminster Ophthalmic Hospital by Mr. C. L. Gimblett. The lecture and the demonstrations are free to medical practitioners. From February 6th to 18th there will be a special course in diseases of children at the Paddington Green Children's Hospital and the Victoria Hospital for Children. The start of the course in venereal disease at the London Lock Hospital has been postponed to February 20th. The course will continue for one month and occupy each afternoon and some evenings with clinical work; lectures will be delivered if there is an entry of six, and early application is therefore requested. A course in medicine, surgery, and the specialties will be held at Queen Mary's Hospital, Stratford, from February 20th to March 3rd; morning and afternoon sessions of lectures, demonstrations, and operations will be arranged. The general course of the Fellowship consists of attendance at the ordinary practice of over forty London hospitals; tickets for any period may be taken out at any time. Syllabuses, tickets, and copies of the *Post-graduate Medical Journal* may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A COURSE of lectures on nutrition in health and disease has been organized by the People's League of Health, and will start on February 17th, at 6 p.m., continuing, with one exception (March 1st), on the following Fridays, until the end of March. Professor Leonard Hill will open the course with a lecture on the nature and purpose of food, and other subjects to be dealt with include historical and geographical considerations, the significance of vitamins, food in relation to growth, dietetic errors, and diet in rheumatic diseases. The fee for the course is 10s., and tickets may be obtained from the People's League of Health, 12, Stratford Place, W.1.

The fifteenth annual post-graduate week for midwives, arranged by the General Lying-in Hospital, York Road, S.E.1, will be held from May 21st to 25th inclusive. The names of those wishing to attend should be sent without delay to the secretary, Post-graduate Week, care of General Lying-in Hospital.

The following members of the medical profession were called to the Bar on January 26th: Dr. G. Wignaraja (Lincoln's Inn), Dr. Norman G. Thomson (Middle Temple), and Dr. Daniel Broderick (Gray's Inn).

MAJOR W. H. WHITEHOUSE, coroner for the south-eastern district of London, has appealed Lieut.-Colonel W. H. Leslie McCarthy, D.S.O., M.C., M.D., D.P.H., barrister-at-law, to act as his deputy assistant.

THE Minister of Health has issued a circular (No. 857) to local superintending authorities under the Midwives Acts announcing that the reasonable expenditure of these authorities on compensation of midwives suspended in order to obviate risk of infection will be eligible for grant under the Maternity and Child Welfare Regulations. It is added that such compensation should normally be calculated on the basis of the loss of income actually sustained by the midwife; exceptional cases are to be reported to the Minister before the authority concerned commits itself to paying compensation.

At a meeting of the Joint Tuberculosis Council on January 21st it was announced that next June there would be a course of post-graduate study at Aiton on surgical tuberculosis; in July a post-graduate course at Papworth and Cambridge; and in October there would probably be one in Edinburgh. At the subsequent luncheon Sir George Newman delivered a short address emphasizing the importance of notification, the dispensary, the sanatorium, and after-care in the tuberculosis campaign. Those present at the luncheon included Sir Robert Philip, President of the British Medical Association, and Dr. C. O. Hawthorne, Chairman of the Representative Body; Sir St. Clair Thomson, president of the Tuberculosis Society; Dr. F. R. Walters, president of the Society of Superintendents of Tuberculosis Institutions; and Mr. G. S. Elliston, secretary of the Society of Medical Officers of Health.

ACCORDING to the Canberra correspondent of the *Times* the Australian Inland Mission of the Presbyterian Church has arranged with the Queensland and Northern Territory Aerial Services, Ltd., for an aeroplane to be at the constant disposal of the medical officer of the mission. The machine will be fitted with a stretcher and will accommodate a nurse in addition to the doctor. In this way isolated settlers will receive medical attention and may be transported to hospital. Consultations will be arranged also with medical practitioners in remote districts.

It is announced in the *Indian Medical Gazette* for January, 1928, that there will be no medical and veterinary section of the Indian Science Congress in 1928. This is because the recent congress of the Far Eastern Association of Tropical Medicine has absorbed the available papers. The section will be revived at the annual Indian Science Congress in Madras in January, 1929, and those who intend to be present, or to read papers, are invited to communicate with Lieut.-Colonel R. Knowles, I.M.S., at the Calcutta School of Tropical Medicine.

It is proposed to endow a chair of surgery in the Women's Medical College of Pennsylvania in honour of Professor William W. Keen, the veteran surgeon who celebrated his 91st birthday on January 19th. The college was founded at Philadelphia in 1850, and Dr. Keen was in charge of the surgical department from 1883 to 1890. Contributions are invited towards the endowment of the new professorship; they may be sent to Mrs. James Starr, president of the college, at North College Avenue and 21st Street, Philadelphia.

The fifth International Medical Congress for Industrial Accidents and Occupational Diseases will be held at Budapest from September 2nd to 6th. Further information can be obtained from the secretary, Council of Industrial Medicine, 12, Stratford Place, W.1.

THE twenty-second Dutch Congress of Natural Science and Medicine will be held at Rotterdam from April 2nd to 4th, 1929, under the presidency of Professor P. E. Verkadé of Rotterdam.

An international congress for the protection of childhood will be held in Paris from July 2nd to 5th, 1928, inclusive, under the presidency of M. Paul Strauss, formerly Minister of Hygiene.

THE centenary of the birth of Professor Eugène Koeberlé, the inventor of haemostatic forceps, has recently been celebrated at Strasbourg.

DR. CESAR JUARROS, a prominent Madrid psychiatrist, has been elected a member of the Spanish Royal Academy of Medicine.

AFTER twenty-five years' active work the Swedish National Society for Combating Tuberculosis has issued a report which indicates that the process of eradication of this disease in Sweden is advancing. Over 7,000,000 kronor (about £380,000) has been received in voluntary contributions, and more than half this sum was raised by co-operation with the Post Office, telegraphic messages being delivered on tastefully decorated forms on payment of a small extra fee, the net profit of which went to the funds of the society. In Southern and Central Sweden there has been a decided decrease in tuberculosis, and fresh efforts are being prepared to combat the disease in the North, where it is still very prevalent. Tuberculous children receive special attention, and in one year free treatment was provided for no fewer than 4,600.

IN the annual report of the United States Public Health Service for the year ending June 30th, 1927, the death rate from all causes was given as 12.1 per 1,000 of the population for the year 1926, which is rather higher than the rate for the previous year, the increase being due principally to respiratory affections, excluding influenza, from which that country for the most part was free. The diphtheria rate was the lowest on record, both as regards incidence and mortality; this is attributed to the increasing use of antitoxin and toxin-antitoxin immunization. Declining death rates were shown by tuberculosis, heart disease, diabetes, and nephritis. Small-pox in most parts of the United States was mild, but in some localities severe forms occurred, particularly on the Pacific coast. The infant death rate continued to decrease. Investigation of narcotic drug addiction indicates a reduction in the number of cases, and tends to confirm the opinion previously reached that this is a neuro-psychopathic symptom.

THE "Metalix" x-ray tube, which embodies its own protection, and has already been noticed in these pages (December 24th, 1927, page 1192), is the subject of two booklets published by the manufacturers (Phillips Lamps Limited, 145, Charing Cross Road, W.C.). One of these illustrates many examples of the use of the tube in connexion with couches and screening stands and other outfits of the principal makers of x-ray apparatus. The other booklet explains in clear language the construction of the tube and the method of its use, and emphasizes its value in physical research.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *JOURNAL*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9361, 9362, 9363, and 9364 (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the *BRITISH MEDICAL JOURNAL*, Aitology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER

(Advertisements, etc.), Articulate Westcent, London.

MEDICAL SECRETARY, Mediscera Westcent, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin. Telephone: 4737 (Dublin), and 4738 (Dublin). :Dunsmough Gardens, Edinburgh (telegrams: 4738, 4739, 4740, 4741, 4742, 4743, 4744, 4745, 4746, 4747, 4748, 4749, 4750, 4751, 4752, 4753, 4754, 4755, 4756, 4757, 4758, 4759, 4760, 4761, 4762, 4763, 4764, 4765, 4766, 4767, 4768, 4769, 4770, 4771, 4772, 4773, 4774, 4775, 4776, 4777, 4778, 4779, 4780, 4781, 4782, 4783, 4784, 4785, 4786, 4787, 4788, 4789, 4790, 4791, 4792, 4793, 4794, 4795, 4796, 4797, 4798, 4799, 4800, 4801, 4802, 4803, 4804, 4805, 4806, 4807, 4808, 4809, 4810, 4811, 4812, 4813, 4814, 4815, 4816, 4817, 4818, 4819, 4820, 4821, 4822, 4823, 4824, 4825, 4826, 4827, 4828, 4829, 4830, 4831, 4832, 4833, 4834, 4835, 4836, 4837, 4838, 4839, 4840, 4841, 4842, 4843, 4844, 4845, 4846, 4847, 4848, 4849, 4850, 4851, 4852, 4853, 4854, 4855, 4856, 4857, 4858, 4859, 4860, 4861, 4862, 4863, 4864, 4865, 4866, 4867, 4868, 4869, 4870, 4871, 4872, 4873, 4874, 4875, 4876, 4877, 4878, 4879, 4880, 4881, 4882, 4883, 4884, 4885, 4886, 4887, 4888, 4889, 4890, 4891, 4892, 4893, 4894, 4895, 4896, 4897, 4898, 4899, 4900, 4901, 4902, 4903, 4904, 4905, 4906, 4907, 4908, 4909, 4910, 4911, 4912, 4913, 4914, 4915, 4916, 4917, 4918, 4919, 4920, 4921, 4922, 4923, 4924, 4925, 4926, 4927, 4928, 4929, 4930, 4931, 4932, 4933, 4934, 4935, 4936, 4937, 4938, 4939, 4940, 4941, 4942, 4943, 4944, 4945, 4946, 4947, 4948, 4949, 4950, 4951, 4952, 4953, 4954, 4955, 4956, 4957, 4958, 4959, 4960, 4961, 4962, 4963, 4964, 4965, 4966, 4967, 4968, 4969, 4970, 4971, 4972, 4973, 4974, 4975, 4976, 4977, 4978, 4979, 4980, 4981, 4982, 4983, 4984, 4985, 4986, 4987, 4988, 4989, 4990, 4991, 4992, 4993, 4994, 4995, 4996, 4997, 4998, 4999, 5000, 5001, 5002, 5003, 5004, 5005, 5006, 5007, 5008, 5009, 5010, 5011, 5012, 5013, 5014, 5015, 5016, 5017, 5018, 5019, 5020, 5021, 5022, 5023, 5024, 5025, 5026, 5027, 5028, 5029, 5030, 5031, 5032, 5033, 5034, 5035, 5036, 5037, 5038, 5039, 5040, 5041, 5042, 5043, 5044, 5045, 5046, 5047, 5048, 5049, 5050, 5051, 5052, 5053, ## DRY MOUTH.

"B." asks for suggestions for treatment of a man, aged 66, who, for about fifteen years, has suffered from xerostomia at night time, when he goes to bed. He has to keep small pieces of sugar by his bedside to induce secretion. He is in full work, active, appears much younger than his age, and has no adiposity. He neither smokes nor drinks, nor has done so. The tongue is normal and there is no constipation nor other symptom.

## METALLIC BISMUTH IN THE TREATMENT OF PSORIASIS.

DR. G. VARIAN (Watford) asks if others have tried metallic bismuth in the treatment of psoriasis. He gives intramuscular injections of the metal in doses of 0.1 and 0.2 gram each week, and states that he has obtained complete removal of these patches in most resistant cases.

## CLEANING DENTURES.

"AMICUS" writes: May I suggest to "T. M." the simple expedient of cleaning the denture once a week with homely "vim" powder? When once the carbonized deposit has been removed by fine pumice-stone powder, the powder will keep the denture as new in appearance. I have had fourteen years' practical experience.

## TREATMENT OF VULVITIS.

THE following information has been received in reply to the inquiry by "R." (JOURNAL, January 28th, p. 164):

DR. ADA MCLAREN (London) writes: Has the patient suffering from vulvitis and eczematous condition of the mucus membrane tried ultra-violet radiation? This has been used with success in similar cases.

DR. E. B. FRENELL (Walton, Clevedon, Somerset) suggests washing the inflamed part lightly with lukewarm water, drying with absorbent cotton, and applying immediately nungutum calaminum (B. P.) once or twice daily.

DR. AGNES SAVILL (London) writes: The conditions demand daily patient care and call for the use of many changes in the local treatment. There is always some infecting cause present, usually a vaginal discharge, sometimes a urinary infection; the parts must be protected from contamination by either source of infection during the treatment of the eczema. The use of x rays will give the first impulse towards cure, but must be followed up by daily high-frequency treatment till the swelling diminishes, when gradually increasing doses of ultra-violet light may be employed. As soon as possible the discharge must be dealt with by local ionization; till this can be given, however, a daily mild antiseptic douche will be sufficient in many cases to bring about a cure. The application of mild mercurial ointments and soothing creams, and bathing with boracic lotion, must be carefully carried out by a nurse throughout the difficult early period of the cure. It is of the highest importance throughout the course of treatment to ensure that the patient does not scratch the parts at night. Rest in bed, with the thighs held apart, should be ordered for the greater part of the twenty-four hours.

## INCOME TAX.

## Repairs to Car.

"A. S. G." in 1926 sent his car to the makers for a very complete overhaul. The inspector has allowed the company's charge, but has refused to allow the expense of sending the car to the works and back—two long journeys costing in all £20.

\* \* The cost of sending the car and of obtaining it back again seems clearly of precisely the same nature as the expense of overhaul, assuming that the journeys did not serve a private purpose as well as the main one. If a spare part had to be obtained, obviously the cost of carriage would have been allowed, though it would be similar in nature to the expense which is refused. The point seems to us so clear as almost to make argument difficult. Perhaps our correspondent can draw from the Inspector some indication as to the distinction he seeks to lay down.

## LETTERS, NOTES, ETC.

## TREATMENT OF CANCER BY INJECTIONS OF PERITONEAL FLUID.

DR. J. B. TOMBLESON (London, W.) describes a method for the treatment of cancer which, he states, has been followed by much improvement in two cases. The procedure is as follows: When peritoneal fluid is present it is taken from the patient, and if very thick it may be filtered. In the absence of this fluid, blood is taken from a vein and is defibrinated. The resulting fluid is subjected to the rays from a tungsten arc lamp, without a reflector, for fifteen minutes, and 20 minims of the treated material is administered subcutaneously to the patient. The process is repeated at intervals of two to three weeks, according to the amount of general reaction which results, seven to ten days being allowed after the patient begins to express a sense of well-being. The general reaction has never been severe, but lasts from seven to ten days; there has been no local reaction. Dr. Tombleson's first patient was a married woman, aged 38, in whom laparotomy disclosed a large malignant growth of uncertain origin. She was discharged as incurable, but a year later peritoneal fluid was removed and she was given an injection

according to the procedure described. She was then weak, and distended with a thick and treacly fluid, the legs and abdomen being very oedematous. Six subsequent injections were given and her condition improved considerably, the tumour decreased in size, there was very little distension of the abdomen, and no oedema of the lungs or abdominal wall. She is now living a normal life and is able to dance. The second patient was a business man with carcinoma of the rectum, colotomy having been performed for the relief of acute obstruction. Under this treatment his condition improved very considerably; he has regained the power of walking, the pain is much less, and his weight has increased.

## TREATMENT OF PROSTATIC ENLARGEMENT.

"BM/RMXR" (London, W.C.) writes: With regard to the suggestion of "General Practitioner" (Dublin) in your issue of January 21st (p. 120), spending as a radiologist of not inconsiderable experience I can say that if an adequate dose of x rays of suitable quality—about 75 per cent. of the unit skin dose—is applied to the prostate in cases of simple enlargement, a good result will be obtained after about eight weeks in at least 60 per cent. of cases; a large proportion of the remainder will be cured, for all practical purposes, after a second application. Except for the time given to the actual treatment the patient's ordinary life is not interfered with. I wish it to be distinctly understood that in making the above statement I am referring to cases that come to the radiologist direct from the general practitioner—not via the surgeon. The latter rarely passes on cases of any kind that are still in the curable stage, and evidence based on such has little, if any, value.

DR. PERCY HALL (London) writes: Cases of prostatic enlargement are not at all uncommon in general practice, and, short of operation, no specific method of treatment is available. Prostatic massage and internal remedies, including organo-therapeutic preparations, are, as a rule, disappointing. I have occasionally found, however, that 20 minims of the liquid extract of ergot, given with an equal amount of the tincture of hyoscyamine, three daily for short periods, occasionally produces marked relief from the troublesome symptoms, which may be due to a chronic prostatitis as well as a degree of inflammation and swelling in addition to the actual adenomatous enlargement. If these are removed the pathological remaining permanent enlargement may not be sufficient to cause troublesome symptoms, and may not increase in size. When the prostatic gland is so enlarged that definite mechanical obstruction renders such remedies useless, much can still be done, in my experience, short of operation. Three modes of treatment which have proved useful in my hands may be used in conjunction or separately. The first is the diathermy current by means of a rectal electrode, another electrode being placed above the pubic region; a current of from 0.5 to 1 ampere passed daily, or on alternate days, for a few weeks is frequently sufficient to produce marked relief; secondly, ultra-violet radiation given by means of the Kromayer lamp with a suitably curved quartz electrode in the rectum, twice weekly for ten to twelve doses, will also considerably help. These doses should be sufficient to produce a mild local reaction. Too large doses may result in slight pain and tenesmus, and possibly slight bleeding from the inflamed rectal mucosa; they should be avoided, although, beyond slight discomfort, they do not result in any adverse effects; thirdly, small ionizing or fractional doses of x rays, given bi-weekly or weekly for ten or twelve doses, should produce marked diminution in the size of the prostate gland. The rays may be directed through the rectum, perineum, and suprapubic routes. Powerful apparatus is not required; indeed, better results are probably obtained from equivalent spark gaps of from 5 to 7 inches. So many patients suffering from this distressing condition are given to understand that nothing but operation is of any avail that "General Practitioner's" inquiry is welcome, since the possibility of other remedial measures should be more generally known to the medical profession.

## PROCREATION AFTER PROSTATECTOMY.

DR. T. GARDNER (Brighton) writes: Following up Mr. O. C. Elliott's case (JOURNAL of January 21st (p. 117)) a similar case. A man, aged 60 or 61, married, in 1913, and with no children. She agreed to marriage only on the understanding that there were to be no children. Her husband, whose prostate had been removed two years earlier, had been assured by the surgeon that it was impossible for him to procreate children, but, within a year after their marriage, she became pregnant. In this case also there was no doubt as to the paternity.

## CONJOINED TWINS.

THE GUY'S HOSPITAL GAZETTE for January 28th contains reproductions from photographs of the case of conjoined twins, a short description of which appeared in our issue of January 14th (p. 82).

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 44, 45, and 46 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 46 and 47. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 89.

# A Discourse ON THE PORTRAITS AND PERSONALITY OF JOHN HUNTER.

BY  
SIR ARTHUR KEITH, M.D., LL.D.,  
F.R.C.S., F.R.S.,

CONSERVATOR OF THE MUSEUM AND HUNTERIAN PROFESSOR, ROYAL  
COLLEGE OF SURGEONS OF ENGLAND.

On July 22nd, 1831, the Court of Examiners was seated in the Council Room of the College of Surgeons in London cross-questioning young men who appeared before it as candidates for membership. On the wall behind the examiners there hung, just as at the present time, Reynolds's famous portrait of John Hunter (Fig. 1). Having done with his candidate, the senior member of the court, Sir Anthony Carlisle, rose from his seat and proceeded to feast his eyes on the features of the man who had taught him the principles of surgery forty years before. Presently he began to look closely at the various objects which Reynolds had introduced into the background of the picture, and, having satisfied himself, resumed his seat and wrote on the back of a stray sheet of paper the following note\*:

"In Sir Joshua Reynolds' picture of John Hunter: he has intelligibly portrayed his pursuits by the two exposed plates; the one displays a series of forelimbs, from the simplest foot to the human hand. In the opposite plate he ranges the human skull first and descends to the quadruped with least brains. His elbow rests on a white paper showing radiating lines from a large periphery and terminating at a point under his elbow. The two books are *Natural History of Animals* and *Natural History of Vegetables*. In the background is the skeleton of the great giant, and the example of a spliced spine by an ossific prop." (See Fig. 1.)

In spite of every care Reynolds's portrait of Hunter is not lasting well; it is useless now to seek for details in the background, but these are preserved in the engraving which Sharp made in 1788† from the freshly finished portrait (Fig. 1). Indeed, Sharp, the friend of Reynolds and of Hunter, was the instigator of the portrait; he prevailed on the master-surgeon of the time to sit for the master-artist of the eighteenth century, and was ultimately successful. We may be sure he took pains to get every

detail right in his engraving, and hence it is Sharp's rendering of the background of Hunter's portrait that is reproduced in the illustration given here (Fig. 1). But there is one other source of information preserved in the Royal College of Surgeons—a small but exquisite enamel done on copper by Henry Bone early in the nineteenth century, when the rich colouring of the original Reynolds was still fresh and vivid. The Hunter family had it done, anticipating just what has happened—that the great painter's pigments would prove to be not permanent. Hence it is from these two sources, and the Hunterian specimens in the museum, that we have to reconstruct the objects represented in the background of the original picture.

We may be sure that Hunter, in supplying Reynolds with the materials for a background, picked what he prized

most—objects or representations which illustrated his most cherished discoveries. The folio of drawings which stands open upon the table on which his left elbow rests (Fig. 1) is one of many which his brother-in-law Sir Everard Home committed to the flames. The folio has been opened to show two of Hunter's "graded series"; they give us his conception of the two structures which make man—man—the head and the hand.

In the "head" series the skull of a European is placed at the top; then follows that of an Australian aborigine; then a young chimpanzee's; then a monkey's—a macaque; then a dog's; and lastly that of a crocodile. I had a mind to set these same skulls up again—in the Hunterian order—but the drawings are not given in sufficient detail to permit individual skulls to be recognized. It is strange, too, that although Hunter certainly dissected a chimpanzee and also a gibbon, and has left notes of what he

observed, their skulls cannot now be traced; they are not mentioned in the original catalogues compiled in Hunter's time, nor in those of a later date.

On looking at such a series, with the most highly developed human type at the top and a reptilian form at the bottom, with a bridge of intermediate types between them, the modern student may jump to the conclusion that Hunter had grasped the idea of man's evolution. Hunter may have suspected the truth, but he was held back by just the same obstacle which kept Huxley from giving his complete allegiance to Darwin. Until we have produced varieties from a common stock which are infertile with each other we have not solved the final crux of evolution—the production of new species. That was Huxley's obstacle, and it was also Hunter's; but I am sure neither the one nor the other would be surprised if they knew that practical students of genetics are now removing even this last obstacle.

FIG. 1.—Sharp's engraving of Reynolds's picture of John Hunter. In the background are shown the various objects described in the text. (Photographed by Grove and Boulton from Sharp's engraving.)

\* The note is preserved in the diary of my predecessor William Clift, pupil of John Hunter and first conservator of the museum.  
† William Clift gives the date as 1785, but, as will be explained later, he seems to be in error. The proper date is 1788.

In his "hand" series Hunter shows even greater pro-science. The horse is given the highest place and man is relegated to the bottom of the list. The gap between the extremes—reading the scale in a descending order—is: ox, pig, dog, monkey. The "hand" of the horse is the most

FIG. 2.—Portrait, believed to be that of John Hunter, recently presented to the Royal College of Surgeons by Mr. G. Bucketon Browne, F.R.C.S., F.S.A.

specialized, most highly "evolved," of the mammalian series, and my friend Professor Wood Jones would support Hunter in placing the human hand at the bottom of the primate scale. I do not agree; in many respects man's hand does retain old-world features, but there are others in which it is highly specialized. However, these personal differences are neither here nor there; the broad fact stands out that Hunter had ranged his series of "hands" in the order now accepted by students of evolution—an order which it is clear his pupil Carlisle had not fathomed and which was regarded by Hunter's contemporaries as highly absurd. These "graded series" represent two of the many ideas which went into the flames. We have to thank Reynolds for their preservation.

Sir Anthony Carlisle misread the titles on the two books on the table. The title of the upper is *Natural History of Vegetables*, and contained notes which Hunter kept of his experiments and observations on plants and trees; the lower, *Natural History of Fossils*, was the gleanings of a lifetime from geology and from a study of the fossil remains of animals and plants which had come into his possession. Hunter had a dozen such volumes, each dealing with a particular line of research, but it was these two he wished to accompany him into posterity. They also went missing after the conflagration; fortunately Clift had made abstracts from them, and, strange to say, years afterwards the two original volumes came to light again: Sir Everard Home's son returned them to their rightful owners—the Council of the College. Nor does one wonder, when their contents are known, that Hunter was proud of them. We find that he had ceased to deal with the Mosaic bank of time and had demanded an unlimited chronology to account for what he had seen and found. He had discovered that the secrets of living matter could be wrung from plants more easily than from animals, and the experiments he had performed on seedling beans are only now having their counterparts in the laboratories of the modern experimental embryologist.

He was proud of O'Brien's skeleton; its feet dangle in the background of his portrait. In those limbs lay the

secrets of growth. The giant, although his death belongs to the summer of 1783, was not a public exhibit in Hunter's museum until 1788, when Reynolds was at work on the final portrait of Hunter. The finishing touches were given a year later—1789. Then comes that puzzling specimen placed by the giant's right foot (Fig. 1, background). Carlisle tells us it is "a spliced spine by an ossific prop"—which, translated into modern phraseology, must mean a "bone-graft introduced experimentally for the repair of a broken dorsal spinous process—of an ox or horse." My colleague Mr. Cecil Beadles and all our assistants have hunted high and low for the original of this specimen; it is not in the museum, and there is no mention of it in any catalogue. It must represent one of Hunter's most prized specimens. As to its nature, we must be guided by its representation in Bone's miniature. It is preserved in spirit; the round bottle in which it is mounted is about ten inches high and four wide. The finer arteries of the specimen have been successfully injected with vermilion; it is the shaft of a bone laid open—about the size of the metacarpal of an ass; Hunter selected the metacarpal of the ass for many of his experimental investigations into the repair and living reactions of bone. There is a gap in the bone—apparently half an inch or more has been sawn out. At one side of the shaft, closely adherent to it and crossing the gap, is the "ossific prop," which I take to be a bone-graft, covered by patches of granulation tissue, introduced experimentally to secure the divided bone. In the museum is a series of metacarpals of the ass, showing the results which Hunter obtained while experimenting on the growth of bone and the exfoliation of necrosed areas. The specimen which Hunter had placed in his picture seems to belong to this series; the notes which relate to all these preparations went up Sir Everard Home's chimney in Sackville Street.

On the table by which Hunter sits is placed a specimen protected by a glass shade—one which puzzled my colleagues and myself for a long time. It looks like a successful

FIG. 3.—Portrait of John Hunter by Robert Home. The original is in the rooms of the Royal Society, London.

injection of the bronchial system of the lungs of some animal, but no trace of such a specimen could be found in Hunterian catalogues or collection. The puzzle was solved by Mr. Cecil Beadles; he recognized it as a Hunterian specimen still preserved in the museum (No. 2060.1)—the desiccated and dissected lungs of a man

who had an osteosarcoma of the lower end of the right femur, with secondary bony deposits in the lungs—deposits which had infiltrated and picked out all the ramifications of the bronchial tree. The remaining object in the background of the portrait concerns the sheet on which Hunter's elbow rests (Fig. 1). Carlisle describes the

diagram on the sheet as "radiating lines from a large poriphery terminating at a point under the elbow," but gives no explanation. William Clift does; on Carlisle's note he has written: "The facial angles of the skulls shown on the adjacent drawing"—a bad guess; the diagram has certainly nothing to do with facial angles. In Bono's miniature this drawing is reproduced clearly, and appears to represent a system of vessels—almost certainly arteries—arranged so as to show branchings at various angles, thus illustrating a matter to which Hunter gave much study—the laws which regulate the angle at which a branch artery separates from its parent trunk.

Thus we see that in choosing the materials for the background of his portrait Hunter exercised great care. In the opened folio, showing the graded series of "hands" and "heads," we see him as a philosopher of natural objects; the two closed books bound in sheepskin represent him as botanist and as geologist; the rare pulmonary preparation under the glass shade as pathologist; the drawing under his elbow as philosophical anatomist; the "wet" preparations as experimental surgeon; and the giant's legs as a collector of Nature's wonders.

Hunter was 60 years of age when he was painted by Reynolds; everyone is familiar with the face therein portrayed; reproductions or engravings of the original picture still hold the pride of place in the medical consulting rooms of the English-speaking world. Let me introduce to the reader at this point another picture of Hunter—one still the subject of hot debate, but which I am convinced is a portrait, or representation, of the great surgeon at an earlier date, when he was about 50 years of age (Fig. 2). This picture made its first appearance in public annals on December 1st, 1922, when a collection of portraits and pictures, "the property of L. M. McCormick, Esq., of 11, Hertford Street, Mayfair," 150 in number, "most of them having great names attached to them," was put up to auction at Christie's. Lot No. 131 was catalogued as "Dr. Hunter by Gainsborough"—a half-length portrait representing the subject life-size. When put up for sale the auctioneer stated that no guarantee was given that the portrait was "of Hunter," or "by Gainsborough," but that it was undoubtedly a picture of high artistic merit. Mr. G. Buckton Browne, who has been a keen student of medical portraiture and a collector of pictures all his life, made a close examination of lot No. 131, found evidence of its being a picture done in the latter half of the eighteenth century, and satisfied himself that it was a genuine representation of John Hunter the surgeon; he purchased it, and with great generosity presented the picture to the Royal College of Surgeons. The College thereupon obtained the expert advice of the director of the National Portrait Gallery, the late Mr. James D. Milner, and of Mr. W. T. Whitley; they had no doubt about the picture being of Hunter's time, nor that it was painted

by an artist of standing, but rejected it as a genuine work by Gainsborough. A study of the canvas, technique, clothes, and details proved that the picture had been painted, in all likelihood, between 1765 and 1785; but where had it been in the century and a half which had elapsed between the date of painting and its first public

appearance in 1922? The task of tracing its history was entrusted to Miss M. Tildesley, at present engaged in compiling a catalogue of the craniological collections in the museum of the Royal College of Surgeons and well known by the studies she has published on the portraits of Sir Thomas Browne. She obtained access to the notebooks of Reynolds and of Gainsborough; she discovered, for example, that in 1788, when John Hunter was giving sittings to Reynolds, he was also attending Gainsborough professionally in that artist's fatal illness. She searched the archives of the Royal Academy, the lists of work of eighteenth-century artists, and of all sale catalogues, ancient and modern, but of this picture could discover not a trace.

We are driven back to prove that we have now another genuine portrait of John Hunter on the evidence afforded by the picture itself. The right forefinger is pointing to a skull held in the left hand; it is the skull of a monkey—

almost certainly of the macaque genus—very similar to the monkey's skull which occupies the central place in the Hunterian "graded series." The artist must have drawn from an actual specimen, but, either in a spirit of freakishness or to improve the appearance of an object otherwise rendered faithfully, has given a human outline to the nasal bones. Who in the eighteenth century besides John Hunter made the monkey's skull the central subject of a discourse? There was, of course, another John Hunter—a Dr. John Hunter—who was born in Scotland about 1750, and obtained his M.D. degree at Edinburgh in 1775 by a thesis on "The causes of the varieties of mankind," and afterwards gave himself to military medicine. But he was neither anatomist nor zoologist. He was not the man to be handed down to posterity with a monkey's skull in his hand, for in his thesis he declared that he "looked on the suggestion of ape being transformed into man as monstrous." He became an eminent Fellow of the Royal College of Physicians, but no portrait of him has been preserved.

But what of the features of the man? Are they those of John Hunter? We know the features which Reynolds gave to Hunter at the age of 60, but what do we know of them at an earlier age? The sources of our knowledge are these: first the portrait now in the rooms of the Royal Society, a replica of which was presented to the Royal College of Surgeons by Sir John Bland-Sutton (Fig. 3). That portrait was painted by

Robert Home, the artist, about the time when John Hunter was courting his sister Anne Home, Hunter being then about 40 years of age. We are shown John in gala attire, debonair, seated in a sylvan glade with his dog—half mastiff, half wolf—resting his muzzle confidently on his knee. The coat has no collar but long cuffs, and the waistcoat, embroidered, tightly buttoned. The features are open; the face rather clean-cut, not puffy or full. The next record we have of him

FIG. 4.—Second portrait of John Hunter by Robert Home. The original is in the Royal College of Surgeons, to which it was presented by Hunter's grand-nephew, W. Hunter Baillie, Esq. (Photograph by H. George.)

FIG. 5.—Life cast of Hunter's face taken either in 1785 or 1788. (Photograph by S. Steward.)

is the portrait in oils which hangs in the hall of the College of Surgeons (Fig. 4); it also was painted by his brother-in-law Robert Home, and was done four or six years after the other. Hunter is here shown in working garb; his hair, a deep sandy yellow rather than red, is cut short in front, as in the new portrait, but hangs long about the ears. The colouring of the coat, and indeed the whole picture, catches its tone from the hair. Hunter had changed in the years which elapsed between these two portraits; his face had lost its clean-cut features and become puffy and full. There are three points in this picture to be noted: (1) The long tapering forefinger of the left hand—exactly the same form of finger as points at the monkey's skull in the new portrait. (2) The slight twist of the left side of the nose towards the left side of the face and the asymmetry of its tip—there being a fullness just over the left ala; the same features come out in the new portrait, which is not a study in reds and browns, but one carried out in cool greys, the hair being powdered and the costume toned to match. (3) The well known wart, situated on the right side of the bridge of Hunter's nose, is seen in the second "Home" portrait and also in the new portrait (see Figs. 2, 4, and 5). The new portrait I suppose to have been drawn some years after the second one by Home—somewhere about 1775-78, when Hunter was reaching his fiftieth year. The man is represented in a forceful mood, alert and alive—the work of an artist of undoubted talent.

The third source of Hunter's features—the most reliable of all—is the life cast taken of his face in Reynolds's studio, either in 1786 or 1788, a photograph of which is reproduced here (Fig. 5). The cast shows Hunter's wide mouth and mobile lips—the upper lip very expansive, passing between the deep lateral naso-labial folds. There is no suspicion of rabbit mouth in the cast; the upper dental arch is wide and well formed. The face was not long—about 123 mm. as we anthropologists measure faces—but it was exceptionally wide and rather flat; the width across at the zygomatic arches was 145 mm.; it was especially wide over the jaws or angles of the jaws—about 140 mm.—due in part to the fatness of the cheeks. The forehead was wide but not high; its width, measured on the cast, was 110 mm. The supra-auricular eminences were full and strong, but the supra-orbital ridges had nothing of the sharpness and temporal projections seen so often in a Scottish type of manhood; the width of the forehead on a level

Fig. 7.—From the original pencil drawing of John Hunter made by Sir Nathaniel Dance Holland, R.A., in 1793 (S. A. Sewell). The original hangs in the conservator's room, Royal College of Surgeons.

with the upper margins of the orbits was 115 mm.—very little more than the forehead at its narrowest. The new portrait reproduces the modelling of Hunter's forehead as closely as any of his acknowledged portraits. But there is in the new portrait a narrowing or compression of all the facial features; the upper lip, lower lip, and chin have all the peculiar features which are manifest in the plaster cast, there is a feeling of side-to-side compression in the representation of the face, especially at the jaws; in this the new portrait resembles the second "Home" portrait. One has to remember that the artist has sought to produce, in the Buckston Browne portrait, a "speaking" likeness; Hunter is depicted in the act of giving a

demonstration on a favourite topic. Hunter was short-necked, high-shouldered, and full-chested; the artist has been kind to his sitter in all of these respects; he was also, as we have seen, indulgent to the nasal features of the monkey's skull.

Another source of information regarding Hunter's head is the medallion made by Tassie in 1791, two years before

Fig. 6.—Engraving by Adlard of Tassie's medallion of John Hunter. The medallion is in the Hunterian Collection at the Royal College of Surgeons.

the great surgeon's death, and now preserved in the College collection. This record is of value; it gives a true profile of the head (Fig. 6), and from it and from the Reynolds cast of the face we can make approximate estimates of the shape and dimensions of Hunter's skull. The length of his skull was between 180 and 195 mm., a few millimetres above the average Glasgow male of the nineteenth century. Its width was about 142 to 144 mm., being about 74 or 75 per cent. of the length, Hunter falling thus within the category of "long-heads." His skull, as is so often the case in the Scot of the south-west, was low-vaulted, rising not more than 115 mm. above the level of the ear passages. These dimensions tell us that Hunter's brain surpassed that of the average British male only by a little; its cubic capacity was about 1,500 c.cm. If we turn to the monograph which my friend Dr. Matthew Young wrote on the Scottish skull,<sup>1</sup> founded on material

drawn from the disused graveyards of Glasgow, we find many specimens which in shape and dimensions make a near approach to the Hunterian type. Physically Hunter was in no sense an exceptional man; we can recognize his great inborn gifts only by measuring what he succeeded in accomplishing. He was a man of very short stature, only 5 feet 2 inches, so Clift has recorded. People of his sandy-red colouring and short stature are particularly frequent among the people who live in the western counties—between Wales and Argyll.

Perhaps the most reliable of all Hunter's portraits is

the pencil drawing made by Sir Nathaniel Dance Holland in 1793—the year in which Hunter died. It is almost a true profile (Fig. 7). We note in particular Hunter's small, deep-sunken eyes and his short neck; as he aged, his eye receded and his head sank down more between his shoulders. The new portrait, while it catches a certain curvature of the upper eyelids, gives no suggestion of the eyes being small, but they do not

depart so much in this respect from the eyes of the second "Home" portrait. Hunter's eyes were light in colour—a grey-blue, with a slight pigmentation near the margin of the pupil—as depicted in the Bone miniature. This is the colour which has been given to them in the new portrait.

There is still another portrait which deserves close attention—that preserved in the Apothecaries' Hall (Fig. 8). It is said to be by Reynolds, and I have no doubt it was painted by him. Miss Tildesley has worked out the details of its history. The tradesman who looked after Hunter's establishment, and continued to supervise the Leicester Square property for years after Hunter's death, was James Weatherall, upholsterer in the Haymarket. Mrs. Hunter gave him the picture in question, informing him that it was Reynolds's sketch of her husband. Mr. Weatherall gave it to his nephew, Mr. Thomas Knight, who practised

Fig. 8.—A photograph of the Hunter portrait in the Apothecaries' Hall, London. Its history is given in the text.

in Chelsea, a licentiate of the Apothecaries' Hall, and "one of the livery." Mr. Knight presented it to the Hall in 1857. Now, in her researches into the history of Reynolds's great picture, Miss Tildesley was puzzled by this curious circumstance: From Reynolds's notebook she found that Hunter gave his first sittings, four in number, early in 1786: the sketch then done was shown in the Academy exhibition of 1786 as "the portrait of a gentleman." On its return from the exhibition Hunter gave Reynolds another sitting—in September. Then something happened—probably a dissatisfaction with the result, both on the part of artist and of sitter. Nothing was done in 1787, but in 1788 Hunter again sat three times to Reynolds; then, in 1789, he sat five times—in the afternoon from 2 o'clock to 4 each time. The Apothecaries' picture represents Hunter with a thin, straggling beard and moustache, but the poise of the sitter is exactly that of the acknowledged portrait. The Apothecaries' portrait cannot be a copy of the finished one; the rough materials for the final picture are there, but the inspiration and the finish, in a multitude of details, are altogether lacking. How are we to explain all of these facts—the two quite separate sets of sittings, a sketch by Reynolds, which Mrs. Hunter disliked; "the portrait of a gentleman" exhibited at the Royal Academy in the summer of 1786; its coming home and an attempt to mend it? And, then, why should Reynolds want a plaster cast of Hunter's face? All these things can be explained if we suppose that the Apothecaries' portrait is the picture done in 1786—that it was an admitted failure; that Mrs. Hunter disliked it; that a new one, the final portrait, was painted in 1788-89; that Mrs. Hunter was glad to get rid of the original picture, and gave it to Mr. Weatherall; and that Reynolds succeeded in getting Hunter to shave off his beard and become a fit subject for his art—by the subterfuge of proposing a plaster cast of his sitter's face. It is a painful process for a bearded man to submit his face to the cast-maker; it is easier and better to have the beard removed. That seems the most feasible explanation of a curious sequence of events.

Such, then, is the story of Hunter's portraits, so far as our present evidence will permit us to tell it. Our study has had the advantage of bringing us into close touch with the personality of a man whose like the world will see but seldom.

Lastly, as evidence of the authenticity of the new portrait, I must cite the testimony of one who is better qualified than any of us to recognize a Hunter—Miss Helen Hunter Baillie, the granddaughter of Matthew Baillie, Hunter's nephew, and now the chief living representative of John Hunter's family. She herself reproduces her great-grand-uncle's features and mental outlook with remarkable fidelity, and has been familiar with Hunterian portraits all her life. She has no doubt that the new portrait is that of John Hunter.

[Sir Arthur Keith informs us that there is to be an exhibition of Hunterian portraits and relics in the Museum of the Royal College of Surgeons, Lincoln's Inn Fields, from February 13th to 19th, open to all medical men and students of portraiture. Visitors will have an opportunity of comparing the "new" portrait of Hunter with other well known portraits. A series of specimens have been fitted up to represent the background of Reynolds's portrait. Hunter's chief discoveries in surgery, pathology, anatomy, physiology, zoology, botany, and geology will be exemplified by preparations chosen from the original Hunterian collection. Students of Hunter's history will be interested by an exhibit prepared at the request of the President of the College—Sir Berkeley Moynihan—by Dr. George C. Peachey. By means of maps, sketches, and photographs, Dr. Peachey has succeeded in giving a vivid picture of London in the latter half of the eighteenth century, the "homes" of the Hunters during that period, and what these "homes" look like to-day. Specimens of Hunterian interest have been loaned by the Wellcome Historical Medical Museum, University of Glasgow, St. George's Hospital, Apothecaries' Society, and other institutions, to make the present exhibition as complete as possible.]

## An Address

ON

## THE ACUTE ABDOMEN.

GIVEN BEFORE THE DEWSBURY DIVISION OF THE BRITISH  
MEDICAL ASSOCIATION

BY

E. R. FLINT, F.R.C.S.Eng.,

ASSISTANT SURGEON, GENERAL INFIRMARY, LEEDS.

DURING the years 1924 and 1925 almost one-fifth of the patients admitted to the surgical wards of the Leeds General Infirmary were cases of one kind or another of the acute abdomen, and the total mortality rate of these two years is mainly attributable to these lesions.

*The Commoner Conditions occurring in 1924-25 in Order  
of Frequency (excluding Subacute Types).*

	Cases.	Deaths.
Acute appendicitis ...	1,080	58 = 5.7 per cent.
Strangulated herniae of all types ...	190	43 = 22.6 "
Perforated gastric and duodenal ulcers ...	150	34 = 22.6 "
Acute obstructions ...	139	55 = 40 "
Acute cholecystitis ...	196	6 = 5.6 "
Acute salpingitis ...	48	2 = 4.1 "
Ruptured viscera ...	29	16 = 55 "
Ruptured ectopic gestation ...	16	0 = 0 "
Acute pancreatitis ...	13	9 = 69.2 "

Though these statistics are not sufficiently large to form an accurate index of the order of frequency of these diseases as a whole, yet they illustrate the common types of acute abdomen in an approximately correct order. In some cases the acute lesion is a complication of a disease which has existed it may be for months or years, and has, therefore, given ample warning of the impending catastrophe. Perforated gastric and duodenal ulcers afford a good example, but the same applies to many of the acute obstructions and the strangulated herniae. Certainly over 90 per cent. of gastric and duodenal ulcers have shown their existence by characteristic indigestion over many years.

Further examination of these statistics brings to light another unsatisfactory feature, and to illustrate it I will analyse the acute appendicitis figures. In 1925 the cases of acute appendicitis admitted numbered 612, and of these 301 (almost half) were complicated by abscess, or diffused or general peritonitis. When appendicectomy was performed before these complications arose there were no deaths, so that the mortality is confined to one-half of the cases, and these all late ones. It is this "too late" factor which is responsible almost entirely for the high mortality of the acute abdomen: I wish to emphasize this most strongly, and at the same time to say that the time is brief between the onset of the attack and the "too late" period; it does not as a rule exceed forty-eight hours, and after twelve to twenty-four hours the margin of safety is rapidly passing.

The surgeon may make his contribution to the mortality by performing unsuitable operations, but I think it is fair to say that he has little or no share in the "too late" episode. There can be no doubt the responsibility lies between the medical practitioner and the patient, or perhaps, more correctly, the patient's friends. The more I see of acute abdominal conditions the more convinced I become that it is the friends who waste the time. In no disease is this better exemplified than in acute appendicitis. There is too often a meddling household therapy as well. The patient, often a child and so unable to fend for itself, complains of bad stomach-ache and is promptly given a dose of castor oil. There is no more certain way of spreading infection to the peritoneum than by stirring up the intestines with aperients at the beginning of a local inflammation such as appendicitis; when it is seen that the pain is worse the doctor is summoned, and by this time probably the appendix has perforated, and, of course, the doctor or the surgeon receives the blame if the result of an operation is unsatisfactory. I recently advocated a campaign of public education, properly controlled, in

certain medical matters. I feel convinced that without it progress will be terribly slow. Even if only one statement were thoroughly driven home—namely, that it is dangerous to give an aporiont for acute abdominal pain without the sanction of a doctor—I feel sure we should see an immenso and immediate improvement in the outlook for the acute abdomen.

I do not intend to say much about operative technique; I shall confine my remarks to diagnosis, in the hope that what I have to say may be of use in focusing attention on the all-important twelve hours following the onset of the acute attack. The surgeon is really of quite secondary importance in this connexion; the man who has the greatest opportunity of reducing the operative mortality is the physician. It is true that operative skill and a knowledge of the best pre- and post-operative treatment are of great importance in such a condition as acute intestinal obstruction, but in early cases of acute appendicitis—and these make up the bulk of the acute abdominal lesions—any surgeon of average competence can show a death rate of *nil*, even over a long series. The credit for this lies entirely with the physician, and it is he who should receive it, though he by no means always does. In the later cases operative skill is of great moment, but even the most accomplished surgeon cannot put back the clock, and he will often be unable to repair what lost time has effected.

It will be seen from the table that acute lesions can roughly be classified into four groups: (1) inflammations; (2) perforations; (3) obstructions and strangulations; and (4) haemorrhages. This is not a scientific classification, for many of the perforations are the result of inflammatory diseases—for example, gastric and duodenal ulcers. But the perforation, which calls so urgently for treatment, is not necessarily immediately preceded by an obviously acute inflammatory stage. On the other hand, acute inflammatory diseases, such as appendicitis, frequently go on to perforation, but here there is, as a rule, a definitely recognizable inflammatory period before the perforation occurs, and it is with this early stage I am concerned. It is for this reason I have made this differentiation between groups 1 and 2.

Each of the four groups has its definite signs and symptoms, and once a particular case has been firmly placed in its proper group it is not difficult to find out the individual organ concerned, if a thorough examination be made and a clear history be elicited.

The signs and symptoms of an acute inflammatory lesion are pain, localized tenderness and localized rigidity, vomiting, quickened pulse, and raised temperature. Those of the second group are pain, more widespread tenderness and an equally widespread rigidity, possibly vomiting, rather quickened pulse, normal, or possibly subnormal, temperature. Those of the third group are pain, very slight, if any, tenderness, no rigidity, persistent vomiting, rather quickened pulse, temperature around normal, and absolute constipation. Those of the fourth group are pain, tenderness, slight rigidity, a distended, rather doughy, abdomen, possibly shifting dullness, usually some vomiting, rapid weak pulse, subnormal temperature, pale face and mucous membranes, syncope, and shallow respirations. The more advanced the condition the more the groups fade into one another in a common peritonitis.

On paper there does not seem to be much to distinguish groups 1 and 2, but a detailed examination of the signs and symptoms will soon dispel this opinion. Let us take acute appendicitis as a typical instance of the first group, and a perforated duodenal ulcer as one of the second. An acute inflammatory lesion of the appendix, in common with a similar lesion in all parts of the small intestine, gives rise to pain referred in the first place to the upper abdomen and umbilical region. The intestine and its visceral peritoneum, unlike the parietal peritoneum, has no appreciation of ordinary tactile sensation; pain occurs when the walls are stretched either by some obstruction to the outflow of the contents, or to exudation of inflammatory products into the wall, and the reason pain is felt in the upper abdomen is that the splanchnic nerves converge on the solar plexus situated in this area. This pain ceases when tension is relieved by the pouring out of the

exudate into the peritoneal cavity or intestinal lumen. As soon as the parietal peritoneum over the inflamed organ becomes involved the pain is localized to the region in which the organ is situated, and spreads outwards from it as the infection continues to involve a wider area of peritoneum. It is coextensive with the tenderness and muscular rigidity. Pain in the first instance—that is, when the intestinal wall only is involved—is of sudden onset, increasing in intensity as the tension from oedema increases, and of a colicky nature, due to intestinal contractions which, while they last, exaggerate this tension. The peritoneal pain, besides being constant, is of a stabbing nature.

Tenderness is due to inflamed peritoneal surfaces rubbing together, or to pulling on light adhesions either by pressure or by muscular movements, such as occur in appendicitis, from contractions of the ilio-psoas when the leg is shifted from one position to another. Rigidity is a protective mechanism, an attempt to limit movement of all kinds, and it is situated over the inflamed site through interaction between the peritoneal nerves and those supplying the muscles concerned. The extent of the rigidity is an index of the area of peritoneum involved, as no rigidity is present unless the corresponding part of the parietal peritoneum is being irritated. There is one exception to this—namely, when the inflammatory trouble is confined to the pelvis, for here the muscular wall is replaced by the pelvic bones, and so no rigidity is found. This fact has often accounted for a wrong diagnosis in appendicitis. The segmented nature of the rectus makes it possible for rigidity to be confined to limited areas of the abdomen; obviously there would be no use in a protective muscular action at any other point than over the diseased part.

In a few hours the referred pain tends to give place to pain localized over the involved organ, and as the appendix is an organ which occupies different places in different patients the pain is not always felt in the same situation. It may be in or near the gall bladder and kidney regions, or on the left side of the abdomen, or in the pelvis. In the latter situation it may cause frequent and painful micturition, and the need for a rectal examination is obvious. There are few inflammatory lesions in the abdomen which appendicitis may not simulate, and a differential diagnosis will depend to a large extent on the history; though, applying the rule of probabilities, it will usually be found that the appendix is the offender in children and young adults.

The pain of a perforated duodenal ulcer is quite different. It is terribly sudden, and excruciating from the outset, and accompanied by a degree of rigidity seldom found in any other condition. The extravasated contents seem to be particularly irritating to the peritoneum (probably it is the hydrochloric acid), and they trickle down in relation to the ascending colon, so that the tenderness is usually to the right—again bringing appendicitis into the most marked here—the initial pain is always worse, the pulse rate is frequently only 80 or thereabouts when the patient is first seen—that is to say, one of the cardinal signs of shock is absent, a feature not generally appreciated, I think—and there is no rise of temperature. It is as well to remember here that there is one acute abdominal condition which gives rise to as excruciating a pain as a perforated duodenal ulcer, and that is acute pancreatitis; but in this condition there is usually profound collapse with a very rapid and weak pulse and a well marked cyanosis, and the maximum tenderness and rigidity are found in the epigastrium. The adrenaline eye test and increased diastase content of the urine may help.

Traumatic perforations (or ruptures) of the hollow viscera do not as a rule give rise to such agonizing pain in the first instance as does a perforated duodenal or gastric ulcer; this is probably because the tear is usually small, and may become temporarily plugged by pouting mucosa. The tenderness and rigidity are at first localized, and, of course, there is the history of accident. These cases are very confusing at times because they are often associated with shock, and not infrequently with internal haemorrhage. It is in this class of case that a definite diagnosis frequently cannot be made, and a laparotomy will have to be done on suspicion of serious internal abdominal injury.

This attitude is quite justified, for, if one awaits a certain diagnosis, peritonitis or haemorrhage, or both, are usually so advanced that a fatal result is inevitable. The primary shock may be severe, and an operation have to be delayed on this account; but if the patient rallies in two or three hours and still the pulso rate does not drop, it is almost certain that there is some condition needing operative relief. These cases require repeated examinations, and at short intervals.

#### Obstructions.

An early diagnosis in intestinal obstruction is, perhaps, even more important than in the inflammatory conditions. It may happen that an inflammatory condition will get well of itself, but it is extremely rare for an acute obstruction to do so, and after the obstruction has lasted forty-eight hours the operative mortality becomes very heavy; in the table it will be seen that it is about 40 per cent., excluding strangulated herniae. Moreover, it is often difficult to differentiate acute obstruction from spreading peritonitis after the second or third day, when absolute constipation, incessant vomiting, rapid pulse, distension, and great prostration may be found in both conditions.

The three cardinal symptoms of acute obstruction in the early stage are pain, absolute constipation, and persistent vomiting. Pain is most marked when there is strangulation as well—for example, in volvulus and the various kinds of hernia. It is at first sharp and colicky, later more or less continuous, until it ceases with the onset of paralysis. In obstructions of the large intestine it is felt in the lower abdomen. Gradually increasing distension is a prominent sign of obstruction. In the earliest stages it may be confined to particular regions of the abdomen—for example, in obstruction of the small intestine it will be central, whereas in obstruction of the large intestine it may be most marked in the right side, across the upper abdomen, or along the whole course of the colon, according to the site of the lesion. Visible peristalsis may be seen at this stage, if the patient be not too fat, and periodic hardening of the caecum may be felt; this is a very useful sign of colon obstruction at the beginning of the attack. When the acute attack follows chronic stenosis of some duration a tumour may be felt, and it should be a rule always to examine the rectum.

**Constipation.**—This is absolute for both faeces and flatus, but there are one or two points to note. Both may be passed in small quantities with the first enema, owing to the bowel below the obstruction being cleared of its contents. Subsequent enemata will produce no result. Also, to be a dependable sign the enema must be a high one, given with the patient's hips raised. In acute intussusception frequent liquid stools may be passed, as there may be a sufficient lumen in the invaginated gut to allow of this, but other signs clinch the diagnosis, such as haemorrhage from the bowel, a sausage-shaped tumour in the abdomen, and a tumour felt in the rectum, and also tenesmus; and, of course, it is most often seen in children under 2 years of age.

**Vomiting.**—Faecal vomiting only occurs after the third or fourth day, and therefore has no useful place in diagnosis. The first vomit is stomach contents, and has a more or less innocent appearance; later it becomes bilious, and frequently repeated, much more so than in acute gastro-enteritis. The oft-repeated vomiting is in strong contrast to the vomiting of appendicitis, which occurs once or twice soon after the onset of pain, but is not frequently repeated until peritonitis supervenes.

In arriving at an early diagnosis the first question to be settled is whether or no an acute obstruction exists. If present, the earlier an operation is performed the better. The exact position of the actual lesion is not such an important matter; of course, an attempt should be made to ascertain this, and a good history will be most useful in this respect. If there is a sear of a previous operation, it should be kept in mind that adhesions associated with this may be the cause of the obstruction. The hernial apertures should always be examined, and also the rectum. A history of comparatively recent increasing difficulty with the bowels, slight colicky pain at times, possibly a little loss of weight and general well-being, and occasional distension of the abdomen in a patient at, or over, middle

age, would suggest a growth as the underlying cause. A previous history of gall stones should make one suspect that a stone may be impacted in the small intestine. In this condition the symptoms may appear rather insidiously, and visible peristalsis may be well marked. I have been able to diagnose the condition before operation in the last four cases I have seen.

In the early stages of acute obstruction repeated examinations are necessary. It may be impossible to be sure of the condition in the first few hours; if the bowels have not acted or enemata are unsuccessful, if vomiting continues, accompanied by an increasing pulse rate and abdominal distension, even if a definite diagnosis cannot be made, it will be in the best interests of the patient to have a laparotomy performed. A delay of forty-eight hours, when obstruction is present, may clinch the diagnosis, but will usually prove fatal from toxic absorption and the shock of the obstruction.

#### Haemorrhages.

The haemorrhages associated with gastric and duodenal ulcers, cholecystitis, appendicitis, and the like, though acute abdominal conditions, very seldom indeed require urgent operation, and I shall not deal with them here. The pathological lesions responsible for the type of haemorrhage in group 4 of my classification are practically confined to two—namely, those associated with injury, in which case there is a history of accident to guide one, and ruptured ectopic gestation, which I will deal with later.

In the presence of shock which the accident initiates it is almost impossible to say whether bleeding is going on or not. The symptoms are very similar, though with haemorrhage alone there is usually an absence of unconsciousness, cold clammy sweating, and dilated pupils. Sometimes shifting dullness may be found, and is suggestive of haemorrhage; it should be looked for particularly in the flanks and above the pubis, and when found in the early hours before the onset of distension it is a very valuable sign. Bleeding may stop as a result of the low blood pressure associated with the shock, only to begin again as the shock passes off, and one notices an increasing pulse rate and pallor, and the respirations become more shallow. It is essential to chart the pulse rate every half-hour. A slight degree of rigidity is often present, and also localized or diffuse pain. There is also tenderness coextensive with the rigidity. Increasing pulse rate, distension, and vomiting indicate an advancing peritonitis. If pain is due to injury of the abdominal wall alone it may be quite severe, and may be associated with rigidity too, but in this case the rigidity is never so marked as when there is visceral injury, and it yields to light pressure.

If a hollow viscus has been torn, vomiting, perhaps mixed with blood, is a prominent feature, and haemorrhage, tarry or bright red, may be passed by the bowel.

Injury to the kidney is followed by haematuria, possibly a swelling in the loin, and pain radiating into the testis or thigh. A diagnosis of rupture of the bladder depends upon the history and location of the injury, small quantities of bloody urine recovered on catheterization, pain in the bladder region, and constant ineffectual desire to micturate. The injection of fluid into the bladder as a test is unreliable.

Rupture of solid viscera gives the signs and symptoms of internal haemorrhage, but the maximum of rigidity and tenderness will usually be found over the injured organ. Fracture of the lower ribs often accompanies injury to the liver and spleen, and pain may radiate to the shoulders when the injury is to the liver.

In ruptured ectopic gestation there is sudden severe abdominal pain, with collapse and the signs of internal haemorrhage; the face and mucous membranes are blanched, there is great restlessness and thirst, and attacks of syncope, with a rapid, weak pulse. The abdomen is uniformly tender and there is a degree of rigidity, but not so marked as is found in the inflammatory conditions. The abdomen is distended and gives a peculiar doughy sensation to touch, and there is tenderness and fullness in Douglas's pouch. These are diagnostic indications of a

ruptured ectopic gestation if they occur in a woman who has had a long period of sterility, or a history of pelvic disease with irregular menstruation, and especially if menstruation has ceased for six weeks or so, during which the early signs of pregnancy may be seen, and at the end of about six weeks there is a discharge of clots from the vagina, with colicky pain in the lower abdomen.

The treatment is immediate operation, and it is surprising how well these patients do afterwards, even though they may be, and usually are, terribly blanched at the time. I have occasionally given a transfusion of blood, and it seems to help. Blood transfusion may be of the greatest value in those cases where the bleeding is due to injury.

I have not gone into a detailed differential diagnosis of all the surgical lesions included under the heading of the acute abdomen; it would make the paper much too long. In the early stages there is usually little difficulty in deciding which organ is responsible. Again, I have refrained from discussing abscesses and peritonitis. These are complications, and the acute abdomen should be operated on before they appear. If a patient suddenly experiences acute abdominal pain, followed by nausea or vomiting, or both, and this is accompanied by tenderness and rigidity, possibly in some degree over the whole abdomen, but most pronounced over the most painful area (which is suggestive of the site of the lesion), with or without shock, or if with the pain and vomiting there is absolute constipation, there is an acute abdominal condition present which is almost certainly of a surgical nature. If the lesion can be accurately placed so much the better; but this does not matter so much to the surgeon as getting the case early, for he should not tackle the job at all if he is not able to deal with any surgical catastrophe which may be exposed on opening the abdomen.

## TWO CASES OF CARDIAC INFARCTION:

ONE FOLLOWED BY CALCIFICATION OF THE HEART,  
THE OTHER BY RUPTURE.

BY

T. WISHART DAVIDSON, M.B., CH.B., D.P.M.,

ASSISTANT MEDICAL OFFICER AND PATHOLOGIST, CITY MENTAL HOSPITAL,  
LEICESTER.

DURING the past two years there has been a considerable increase in the literature on coronary occlusion, cardiac infarction, and rupture of the heart. The two cases to be described have been put on record owing to certain unusual and interesting features.

### CASE I.

A man, aged 55 (shoe hand), was admitted in June, 1901, in a state of acute excitement with hallucinations. He slowly became demented, but led an active and useful life as messroom worker, vanman, and hospital messenger. In August, 1925, at the annual physical examination, the heart was found to be enlarged to the left nipple line; there was a soft mitral systolic murmur and occasional extra-systoles. The lungs were clear. On November 13th, 1925, he was confined to bed for a few days with bronchitis and slight oedema of feet and legs; there was no albuminuria. He was soon up and about again, working as usual. On the evening of December 12th, 1925, he returned from afternoon leave and complained of not feeling well. He went to bed and slept for an hour; at 10 p.m. he went to the ward commode, collapsed, and died at 10.3. There was no record of the Wassermann reaction.

### Post-mortem Examination.

The heart was greatly hypertrophied and weighed 809 grams (28½ oz.); length from aortic ring to apex, 14 cm.; mid-ventricular diameter, 12 cm.; left ventricular wall, 2.5 cm. thick; right ventricular wall, 0.9 cm. thick. The pericardium was much thickened, and was adherent around the apex over an area 8 cm. wide; a plentiful supply of blood vessels passed from the adherent pericardium to the apex. There was a small quantity of straw-coloured fluid in the pericardial sac. The lower half of the left ventricle was ballooned out sufficiently to contain a golf ball. The anterior wall of this dilatation was fibrous, with scattered patches of calcification and extensive areas of recent sub-endo-pericardial haemorrhage. The apex and the left lateral, medial, and cardinal haemorrhage. The apex and the left lateral, medial, and posterior walls were fibrous, with marked calcareous deposit which was extended 7 cm. along the interventricular septum. There was formation of fibrin on the calcareous nodules that projected here and there through the endocardium, which otherwise was intact, and lined the irregular inner aspect of the dilatation. The myocardium was brownish and soft, and the papillary muscles much hypertrophied. All the chambers were dilated and hyper-

trophied. The aortic cusps were thickened, and the mitral thickened and incompetent. There were a few small patches of atheroma in the ascending aorta.

The left coronary artery was healthy at its origin, but just inside the mouth there was atheroma with early calcareous deposit, 3 cm. from the origin of the main vessel there was complete occlusion of the anterior descending branch for a distance of 2 cm., and beyond that the walls were greatly thickened, with narrowing of the lumen. The right coronary artery showed slight atheroma.

**Microscopical Examination.**—The left coronary artery was atheromatous and occluded by organized thrombus. There was great proliferation of the intima, and fibrous tissue was arranged in whorls around small vessels formed during the canalization of the thrombus. Yellow granules of haemosiderin lay amongst the fibrous tissue. The muscle fibres of the myocardium were irregular

FIG. 1.—Case I. Section through calcified cup in left ventricle: (a) adherent pericardium; (b) calcareous nodules; (c) recent haemorrhage.

in size, stained indifferently, and many were dotted with black granules; fibrous tissue was increased between the muscle fibres. At the apex the muscle fibres were very scanty, and there was abundant white matter. The kidneys were in a state of chronic bronchitis.

Close inquiry revealed no history of any illness nor complaint on the patient's part to point to occlusion of the coronary artery, yet the anterior descending branch had been blocked and extensive infarction of the inferior half of the left ventricle, including the septum, had occurred. The infarct had undergone softening and been replaced by fibrous tissue which had stretched, producing aneurysm of the heart. Extensive calcareous deposit had occurred in the dead heart muscle, and judging from this the patient must have carried on with a damaged heart for a considerable time, possibly years, until he presented signs of heart failure in November, 1925, from which he apparently recovered, but which was followed by sudden death possibly whilst straining at stool. Goodall and Weir report three cases of coronary disease and rupture of the heart in patients who died suddenly in or near lavatories. Crawshaw reports another case of ruptured ventricle in similar circumstances.

Hamman considers that occlusion may occur so slowly that no symptoms mark the final occlusion. Thayer quotes cases of recovery for periods of three years and thirteen years after infarction, and states that ultimately death may be sudden, or from gradual heart failure. The case described certainly bears out these points.

Calcification of the heart is rare. In Gibson's collection of forty-three cases of infarction from English, American and Continental literature there is no example of calcification of the infarct. Scholz describes a case of calcification of an infarct following coronary occlusion in a male, aged 74, demonstrated radiographically *intra vitam* and confirmed *post mortem*. He remarks that where calcium salt are deposited in a cardiac infarct "the calcifying process gradually takes on a massive solid form involving a large area and all the elements of the heart wall. It may be worth noting that this apparent elimination of so large a portion of the heart muscle causes very little distress to the patient unless the conducting system of the heart happens to be interfered with by the calcifying process." Scholz also quotes a case of coronary occlusion, followed by calcification of the infarct, described by Burns in 1898 and a case described by Askanazy in 1901.

## CASE II.

A woman, aged 65, was admitted in November, 1925, in a state of epileptic confusion and restlessness. There was a history of epilepsy for the previous thirty years. On admission the cardiac dullness was normal, but the heart sounds were soft and faintly heard; the action was regular in rate and rhythm. On May 14th, 1926, she complained of pain in the chest, vomited, and breathed with difficulty; the next day the temperature rose to  $101^{\circ}$  F., pulse 120, respirations 38, the pain in the chest was acute, dyspnoea marked, and the face extremely congested. Fever continued for six days, and the pain and dyspnoea slowly passed off. The patient apparently recovered and was up and about from May 25th until June 6th, when she again complained of pain over the heart. From June 24th there was fever ranging from  $99^{\circ}$  to  $100.4^{\circ}$  F., pulse 80 to 100, respirations 20 to 40; dyspnoea, cardiac pain, and cyanosis until June 27th, when there was sudden syncope and death.

Unfortunately, there is no record of the character of the pulse, cardiac dullness, sounds and action, or of the presence or absence of pericardial friction, etc., and the case was not diagnosed during life. The Wassermann reaction was negative.

*Post-mortem Examination.*

The heart was hypertrophied and weighed 481 grams (17 oz.); length from aortic ring to apex, 10 cm.; mid-ventricular diameter, 8 cm.; left ventricular wall, 2 cm.; right ventricular wall, 0.75 cm. thick. The pericardial sac was distended and contained over two pints of fluid blood; clot was wrapped around the heart like a cast. The pericardium was adherent around the apex and to the anterior surface of the right and left ventricles over an area 6.5 cm. wide. Blood oozed from the left ventricle along the edges of the pericardial adhesions. There was infarction of the apex of the left ventricle involving the myocardium for a distance of 4 cm. along the interventricular septum. A laminated thrombus 3 cm. thick filled the apex. The myocardium appeared healthy; the anterior cusp of the mitral valve and the aortic cusps were thick and fibrous; the valves were competent. The aorta was atheromatous at the arch.

The left coronary artery was healthy at its origin, but 1 cm. from its mouth the vessel was thrombosed for a distance of 2.5 cm. The right coronary artery was healthy.

*Microscopical Examination.*—The left coronary showed irregular "signet ring" proliferation of the intima, with final occlusion of the lumen by thrombus which was being organized. The infarct showed necrotic muscle fibres. There was active phagocytosis by large multinuclear cells and leucocytes; bands of white fibrous tissue replaced the dead muscle fibres, and the

FIG. 2.—Case II. Section through left ventricle; (a) adherent pericardium; (b) infarct; (c) laminated thrombus.

pericardium adhered by a delicate fibrous tissue meshwork, in which there were small haemorrhages. The lungs were healthy. The kidneys were pale and fatty, and the vessels sclerotic.

There were no marked signs of cardiac disease until coronary occlusion occurred; then there was sudden acute cardiac pain, dyspnoea, vomiting, and fever lasting ten days. The patient apparently recovered and was able to be up and about for a period of four weeks; meantime ischaemic necrosis had occurred. Pericardial adhesions formed over the infarct and were apparently efficient for four weeks, when, presumably, stretching of the infarct took place with bleeding into and through the softened tissue to the pericardial sac along the line of the adhesions, resulting in haemopericardium. Hamman<sup>2</sup> considers that it is exceptional for a softened infarct to rupture and cause death soon after occurrence of the occlusion.

I am indebted to Dr. J. Francis Dixon, medical superintendent, for permission to publish particulars of the above cases.

## AURICULAR FLUTTER.\*

BY

C. E. K. HERAPATH, M.C., M.D.,  
 ASSISTANT PHYSICIAN, BRISTOL ROYAL INFIRMARY.

AURICULAR flutter is an abnormal heart rhythm the diagnosis of which is difficult in the absence of instrumental methods, but usually possible if certain points are considered.

The fundamental factor of the condition is that the auricles start a very rapid rate of contraction, somewhere in the neighbourhood of 300 times a minute. The diastolic period allowed at that rate is so short that the ventricles are not properly filled and their output is diminished. The ventricles are usually unable to follow the auricular

FIG. 1.—Shows auricular and ventricular rate at 264. 1:1 flutter.

rate owing to the conductivity of the bundle of His being unequal to such rapidity of function, and for that reason every other stimulus is held up by the bundle and a condition of 2:1 heart-block is set up; this is really a protective heart-block, which is useful in that it protects the ventricular muscle from exhaustion following on an extreme tachycardia. Exercise, which stimulates the sympathetic, is known to increase the conductivity of the bundle, and sometimes it is found that exercise may cause the ventricles to follow exactly the auricular rate for a short time (Fig. 1).

Usually a 2:1 block is present, so that the ventricular rate is about 150 a minute; and this rate is very constant—it remains the same whether lying, standing, or even moving about. Sometimes the ventricular rate is about 75—a 4:1 block—and this is where we are very apt to miss the condition on a cursory examination, but really it is the best chance for diagnosis. If exercise is given the rate, instead of rising slowly, jumps with a sudden bound to double the original rate—namely, about 150—or in some cases it may become quadrupled to about 300. This is characteristic of flutter, and there are only two conditions where this may occur: in a trained athlete on exercise the rate may rise with a jump from about 60 to 120, and on rest the same thing may occur in the opposite direction; auricular flutter is the other. It is commonly said that this may occur in paroxysmal tachycardia, but, although sudden jumps of rate do occur at the onset and offset of the attacks, the increase is not a multiple of the former rate.

In flutter an intermediate rate may occur, for the block may vary between 2:1, 3:1, and 4:1; in this case there is ventricular irregularity, and the clinical diagnosis then becomes still more difficult. The symptoms to be expected are some degree of heart failure if the rate be much above normal, owing to deficient ventricular output, yet, clinically, at rest the heart may appear to function properly. The size of the heart may be little if at all increased; the rate may, as we have seen, be about normal. Occasionally a constant ripple may be seen in the jugular vein in the neck, corresponding to the auricular contractions, but this is not often present. The chief points for diagnosis are an unvarying rate over long periods, unless by doubling or quadrupling, associated with breathlessness.

The condition may occur in apparently healthy or in obviously diseased hearts; it is essentially a similar condition to auricular fibrillation, the former being a regular tachycardia, whereas the latter is an entirely irregular

\* Received for publication June 20th, 1927.

tachycardia. The one condition may very easily pass into the other, and, in fact, may be made to do so by means of drugs.

The treatment consists of the administration of digitalis or quinidine, or both at the same time; its results will be demonstrated in the cases recorded below.

## CASE I.

A strong, healthy-looking man, aged 28, was invalided out of the army with disorderly action of the heart. He received a pension for five years, and then it ceased as he was considered well. Eighteen months later he developed extreme tachycardia on exertion and was sent to my out-patients' department. The size of the heart was doubtful, but a radiogram showed that it was very much enlarged. There was a soft systolic murmur at the

FIG. 2.—Shows 2:1 block in auricular flutter. P, auricular waves; R, S, and T, ventricular waves.

apex. The rate was 132 at rest, but this rose to 264 on exertion. The condition was manifest. He was given 2:1 flutter at rest (Fig. 2), but 1-1. He was admitted and placed on 1 minims thrice daily, and in a few days the ventricular rate was slowed owing to a mixture of 2:1, 3:1, and 4:1 block (Fig. 3). Digitalis was continued (15 minims thrice daily) for three weeks, with no effect but that the block became 4:1. Quinidine was then given.\* The condition changed from flutter to normal rhythm after the third capsule, so no more was given; flutter, however, recurred the next day. A further course of quinidine was ordered, and again he became normal after the third dose, but this time he was given two capsules the next day, and then one capsule a day for fourteen days. He remained at normal rhythm and was discharged. He continued well for eight months, but was then taken ill again after walking up a steep hill. Flutter was again present. He was once more put on digitalis, and this time on the third day the condition changed to auricular fibrillation (Fig. 4). The digitalis was at once stopped—for if one can force flutter into fibrillation the heart often lapses into normal rhythm as the effect of the digitalis wears off; however, he relapsed into flutter. Digitalis was again administered, and quinidine was given, but

FIG. 3.—Shows a mixture of 2:1, 3:1, and 4:1 block. P, auricular waves; R, S, and T, ventricular waves.

the full five doses had no effect. Digitalis was continued and the condition again changed to fibrillation. On stopping the drug this time he regained normal rhythm; this has remained so till the present time, a matter of four months (Fig. 5).

The next two cases came on after an attack of influenza.

## CASE II.

A woman, aged 36, was sent to hospital by her doctor, who described her as a case of heart failure which was obscure, as the heart did not appear clinically very bad. She had influenza in 1922, and six months later her feet began to swell. A year later she had ascites, oedema of the legs, and palpitation, which gradually got better, but she remained very breathless. She was admitted in June, 1924. The heart was enlarged to a slight degree, there were no murmurs, and the pulse rate was 144 per minute. A tracing showed 2:1 flutter. Digitalis changed the block to 4:1, but nothing else happened; the rate was then 72 a minute. She was given quinidine, but the second capsule made her feel very ill and it was stopped. She therefore remained

\* The method is as follows: a preliminary dose is given of 0.4 gram in a gelatine capsule, to see that there is not an idiosyncrasy against the drug, and the next day the patient is given 0.4 gram every two hours for five doses.

on digitalis, and I went on holiday. On my return I was informed that she had died, and therefore she had been taken off. I showed that the rhythm was normal, and it till the present time.

## CASE III.

A boy, aged 17, had an attack of influenza during which he was taken with vomiting and extreme tachycardia associated with much dyspnoea, but no signs of heart failure. The tachycardia continued for eight months. I saw him in August, 1921. The heart was not enlarged and there were no murmurs. The pulse rate at rest was 144, but on exercise this went up to 238 with pulsus alternans, as shown by the electrocardiogram. Auricular flutter was diagnosed, but no treatment was given at that time. He was given digitalis 15 minims thrice daily, and he was kept at this rate for a long time. Holiday time came on and I went away. On my return I found the

FIG. 4.—Shows auricular fibrillation. The ventricular rhythm is quite irregular. P, fibrillation waves in diastole.

rate at 60, and, judging that the flutter had ceased, the patient was allowed up, and it was found that the tachycardia had passed off. He was sent up to London to see Dr. Parkinson, who reported that the electro-cardiogram was normal and that the heart also appeared normal. Since then the boy has never looked back; he has played Rugby football and gone through his course as a medical student. He appears to have a normal heart. It was unfortunate that I missed the turn over of both these cases, but probably the flutter was followed by fibrillation and then reverted to normal rhythm.

## CASE IV.

A man, aged 50, had suffered with emphysema of the lungs with cyanosis for some years, but for the last four months had oedema of the legs with a sensation of fluttering in the chest. His heart was enlarged, the sounds were faint, but there were no murmurs. The pulse was irregular, and a tracing showed auricular flutter with a varying block—3:1 and 4:1. Digitalis kept him at a regular 4:1 block, but did nothing further. He was given quinidine, five doses on two consecutive days, with no effect, so digitalis was pushed till fibrillation ensued. On stopping the digitalis the flutter returned, but on repeating the process the

FIG. 5.—Shows normal rhythm. The ventricular waves are the same, R and T. There is only one P wave occurring just before the a wave.

rhythm returned to normal and he was discharged. Six weeks later he relapsed and flutter reappeared.

## CASE V.

A man, aged 37, had had rheumatic fever at an early age, with three recurrences since, the last being in August, 1926. He was admitted on September 1st, 1926, suffering from gross heart failure with a very rapid regular pulse of 182 a minute. An electro-cardiogram showed flutter with 2:1 block. This is a very high rate for a flutter, for the auricular rate was 364. The next day the heart was found to be grossly irregular, and the condition had changed to fibrillation. As he had advanced mitral stenosis it was thought he would do better if the fibrillation was made permanent, so he was given digitalis and the rate slowed to about 75 a minute, and was kept at that rate by a dose of 15 minims of tincture of digitalis thrice daily. He did very well, and has since gone back to work, which is luckily not of an arduous nature.

The number of cases here reported is too few upon which to base any remarks, but it is interesting to note that the two influenzal cases are the only ones which have not recurred—once over a period of three and the other of six years. The probability is that they will not now recur.

## ESTIMATION OF GLUCOSE IN THE BLOOD AND CEREBRO-SPINAL FLUID.

BY

FRANCIS TEMPLE GREY, M.A. OXON.,  
M.B., CH.M. SYDNEY,  
PATHOLOGIST, EAST LONDON HOSPITAL FOR CHILDREN.

HAVING had excellent results with Maclean's method<sup>1</sup> in a large number of determinations of glucose in the blood and cerebro-spinal fluid, it has occurred to me that my experience might be of interest. To ensure success certain points must be attended to which, although doubtless very elementary, have been found to be neglected in some cases where I have been consulted. The difficulties appear to be of three orders: personal, physical, and chemical.

The most frequent mistakes common to all methods are those of arithmetic, careless reading of the burette, and the use of odd slips of paper instead of a properly kept notebook. Not the least advantage of the well kept notebook is that the titrator may leave his entries to be afterwards dealt with by another; indeed, one might go so far as to say that a notebook of which another worker cannot make head or tail has not been properly kept.

Next to mistakes in arithmetic come errors which arise from an absence of the proper physical conditions. On one occasion a flask awaiting titration, the iodine having been liberated, was left standing in the sun; in others the proper heating conditions had not been obtained; thus on one occasion a wire gauze of another mesh than that with which the flame had been standardized was used.

Last, but not least, the reagents may be at fault. In one laboratory, for instance, after exhausting every other possible source of error, the sodium sulphate supplied by a reputable firm was found to contain sulphite. More often the "dialysed" iron is found to be at fault and to contain free hydrochloric acid. If the worker does not make up his own volumetric solutions it is as well to have the titre of the thio—supplied by commercial houses as decinormal—checked.

Professor Maclean's method may be divided into stages as follows:

**Stage I (Deproteinization).**—Into a 50 c.cm. Erlenmeyer flask take 23.8 c.cm. of 15 per cent. sodium sulphate acidulated to the extent of 0.1 per cent. with glacial acetic acid. (Sodium sulphate solution which has lost its acidity may be reacidulated.) Add 0.2 c.cm. blood; raise just to the boil; add 1 c.cm. dialysed iron; filter through starch-free filter paper, whose diameter is about 4 inches, into a small Erlenmeyer flask.

**Stage II (Reduction).** The filtrate, or 20 c.cm. of it, is transferred to a larger flask and allowed to cool either automatically as it waits its turn, or under the tap; add 2 c.cm. standard copper solution and reduce under standard conditions—that is, raise to the boil in one and a half to two minutes and keep boiling for another six minutes.

**Stage III (Titration).**—Cool as above, and when ready to titrate, but not before, liberate the iodine with 2 c.cm. 75 per cent. HCl. Add a few drops of starch solution and titrate against N/400 sodium thiosulphate.

Modifications of methods are in general to be deprecated unless they make for simplicity and give constant results. To take these modifications in turn.

I. There is no need for a reflux condenser at this stage, as scarcely any fluid is lost by bringing the lysed blood just to the boil. The dialysed iron may be added immediately; if a good sample—and poor samples of dialysed iron must on no account be used—its effect is instantaneous and the fluid may be filtered hot; in fact, it filters more quickly hot. The filtrate, measured before any evaporation has taken place on standing, is very constantly 21 c.cm., so that, if one likes, the whole filtrate may be taken, multiplying the result by 0.95. Obviously, if evaporation has occurred to any extent, as may happen when large numbers are being dealt with, it is even more accurate to take the whole filtrate than to imagine that 20 c.cm. obtained with difficulty represent 4/5ths of the sugar in the blood taken, when in reality it represents slightly more—that is, up to 21/25ths.

II. Reduction must take place under the standard conditions laid down by Professor Maclean. I find it

convenient, but not essential, to use a reflux condenser at this stage in order to avoid over-concentration. The condenser need not even be reflux. Clamp a large test tube filled with cold water, and adjust it immediately over the flask; the column of water will eventually become heated up, but not before it has prevented the over-concentration in the flask. The standardization of the flame by a manometer is unnecessary and unreliable—unnecessary because the observer's ear soon becomes accustomed to the sound from a given Bunsen burner at a given gas pressure; unreliable because heat supplied does not vary exactly as the pressure, but depends on the gas quality (thermic value). It is better, therefore, to find by trial the size of flame which will bring materials to the boil in from one and a half to two minutes, and reckon six minutes more (preferably by an interval alarm clock). This procedure gives more freedom as to the kind of flask used, for if the manometer is depended on it will make a difference whether, for instance, Bohemian or Swedish flasks are used.

III. It is not necessary, when liberating the iodine with strong acid, to wait for the effervescence to pass off, as this will occur during the shaking in the titration. A blank titration of the standard should be done with every batch of blood sugars—say twice a day. This is especially necessary if the standard is made up in bulk, for the solution ripens on keeping, and its value may rise so that 2 c.cm. are equivalent to 13 c.cm. of N/400 thio. When filling up the bench bottle (which is preferably of brown glass) titrate and correct, if necessary, as follows:

Suppose the value to be 11.7, take 110 c.cm. of the stock solution and add 7 c.cm. H<sub>2</sub>O, and so on; or the correction may be made arithmetically. Make up the N/400 sodium thiosulphate as follows: take 24 c.cm. N/10 sodium thiosulphate into a 100 c.cm. volumetric flask—a graduated glass cylinder is not accurate enough—add distilled water to the mark; empty out, shaking the while, into a larger flask and shake thoroughly. Volumetric flasks are for measuring, not for mixing.

Finally, the technique should be checked by seeing that reasonable results are obtained with normal bloods—that is to say, a figure around 0.085 per cent. in the case of a healthy person during the last hour before lunch—or with a known solution of glucose, say 1/4 per cent., which will keep if a little toluol be added.

Until everything is going well one should be prepared to do two or three titrations on any one particular case. For this purpose 1 or 2 c.cm. of blood should be taken either from the ear or from a vein, and the blood collected in a small tube which has been rinsed out with 20 per cent. potassium oxalate solution and dried.

When everything is going well, 0.2 c.cm. of blood is drawn into a pipette having preferably a capillary mouth subdivided, if possible, to 0.05 c.cm. A small length of rubber tubing (1/8 to 1/4 in. bore) makes a useful tourniquet; wind one turn just past the last joint of the thumb, leaving a small space on the dorsal aspect of the thumb between the joint and the nail. The advantage of this little plateau is that the blood is not so likely to run off it. Stab boldly; have a watch-glass (with a trace of potassium oxalate on it) in readiness to catch any overflow in case the bleeding is unexpectedly energetic. The pipette after use is washed out with water and then in potassium oxalate solution and set aside to dry; more than one should be at hand.

The time at which the blood is taken should be noted. If many hours elapse between the taking of the blood and its titration a misleadingly low reading may be obtained, even if the blood has been kept on ice. This seems to be due to ferment action, and may be inhibited by adding a trace of formalin. It is often convenient, however, to do Stage I (which destroys the blood enzymes) in the consulting room, the filtrate being reserved for reduction and titration at leisure.

## Cerebro-Spinal Fluid.

Here the estimation is as for blood, except that where globulin is not increased the first stage (deproteinization) may safely be omitted, as the cerebro-spinal fluid contains normally a hundred times as little protein as the blood. When, however, globulin is increased, 0.1 c.cm. dialysed iron may be used—that is, ten times as little as for blood. The normal glucose content of the cerebro-spinal fluid is somewhat lower than that of the blood, and is fairly constantly about 60 mg. per 100 c.cm. There may be none in acute meningitis.

## THE HISTORY OF A HYPERNEPHROMA.

BY

K. V. TRUBSHAW, F.R.C.S.Ed.,  
SURGEON, CHESTER ROYAL INFIRMARY.

ALTHOUGH the vagaries of hypernephromata are well known, the following case is so unusual that it is worth recording.

In August, 1924, a girl, aged 15, was admitted to the Chester Royal Infirmary with a hard, firm, rounded mass occupying the left loin. The urine had a specific gravity of 1020, and contained a trace of albumin, but no blood or pus. She stated that she had had attacks of vomiting and of pain in the left side for some years and that, shortly before admission, she had noticed a swelling in the flank. She was extremely emaciated, with a remarkable growth of hair over all the limbs and abdomen. The skin had a dusky tint, but there was no premature development of the sexual organs; in fact, menstruation did not start until the following year.

*Exploratory Operation.*

A tentative diagnosis of hypernephroma was made, and the kidney explored through a lumbar incision. It was found fixed and surrounded by a reddish vascular growth. As nephrectomy seemed to be out of the question a small piece was excised for microscopical examination. This was reported to be a typical hypernephroma. She left the hospital with an unhealed sinus and I did not see her again until about two months later. She was then a living skeleton, covered with an abundant growth of hair, and it seemed impossible that she could live much longer. I heard later, however, that she remained in this condition for about nine months, and then, to everybody's surprise, began to put on weight, the tumour and the hairy growth disappearing.

*Nephrectomy.*

She was readmitted on September 28th, 1927. She was now a well developed girl of average height and weight and had been going about apparently in the best of health until three weeks previously, when the pain in the side reappeared. We found a rounded, tense swelling beneath the old scar. The urine contained pus and gave a vigorous growth of *B. coli*. A pyelogram of the left kidney showed the tumour to consist of a greatly distended pelvis and main calyces. Radiograms of the thorax and long bones were taken and showed no signs suggestive of metastases. An exploratory operation showed the kidney to be densely adherent to the surrounding tissues and to the peritoneum. As she took the anaesthetic badly, a drain was inserted and a large quantity of pus evacuated. Three days later the wound was reopened and subcapsular nephrectomy performed.

The wound has now (November 28th, 1927) practically healed and her general condition has immensely improved. The report on the kidney by Dr. Grace, pathologist to the Infirmary, was as follows:

"Much chronic inflammatory change with patches of acute inflammation and small abscesses here and there; very little renal tissue left; no evidence of tubercle, new growth, or hypernephroma."

Dr. Grace is also responsible for the original diagnosis, and one which was supported by the naked-eye appearance of the tumour and the general condition of the patient.

The dilatation and infection may have been present throughout, but it does not alter the fact that there was a growth found at the first operation, and that we could find no evidence of one three years later. It would seem to be a curious instance of the waxing and waning of malignancy to what we hope is a final disappearance.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

FORMALIN INJECTIONS IN GANGRENE OF  
THE LEG: RECOVERY.

THE following case is unusual in view of the method of treatment and the ultimate recovery of the patient after having a dead limb attached to him for four months.

In September, 1925, an outdoor worker, aged 59, of temperate habits, had a severe attack of enterocolitis lasting eight days, which brought him to the drained and shrunken appearance of a cholera case. On September 26th, the eighth day of the disease, when the temperature had fallen and the bowel evacuations were normal, he experienced a sudden feeling of "pins and needles" in the right leg, followed by acute pain of gradual onset. His temperature was 97°, and the pulse rate 88. The foot was blanched and the thigh slightly blue; no pulsation could be felt in the femoral artery from a point one inch below Poupart's ligament. The specific gravity of the urine was 1040; no albumin or sugar was present.

The diagnosis appeared to be embolism of the femoral artery by the detachment of a thrombus which had probably formed at the bifurcation of the iliac arteries. In two days a demarcation of irregular outline was very pronounced at the junction of the middle and upper thirds of the thigh. He was then seen in consultation with my partner, Dr. H. Townsend-Whitting, and it was decided that the patient was not likely to survive the operation of amputation at the hip-joint, and that, if he did survive, he would probably die from gangrene of the flaps.

The leg was swabbed with spirit daily, powdered, and completely encased in cotton-wool. On October 3rd, feeling that prevention of decay was the only hope, I started periodic injections of formalin, 1/2 to 1 drachm, into the tissues of the leg. The injections were both superficial and deep, and the strength varied from 2 to 40 per cent., according to the distance from the demarcation line. The course was perfectly afebrile till October 17th, when the temperature reached 99°. It fell to normal on the 20th to 22nd, but reached 101° on October 24th and 101.8° the following day. The temperature had returned to normal on November 1st, after which there was only an occasional evening rise of one degree.

From October 20th onward there was profuse discharge of pus from the demarcation line, and some gas formation in the thigh. The occlusion of the artery spread slowly upwards, and by December 2nd the pulsation, which had been felt above Poupart's ligament, had disappeared.

On December 25th a rubber tourniquet was applied just below the demarcation line to hasten separation.

On January 7th, 1926, an incision was made below the tourniquet and the bone isolated. The muscles divided were brown, with the exception of part of the adductor magnus, which was pink and was slightly sensitive. Further formalin injections were made in and round the sciatic nerve, which was sensitive for several inches below the line of demarcation.

On January 18th the sciatic nerve was divided, giving rise to slight and momentary pain. The next day the femur was sawn through about the junction of the middle and lower thirds. The medullary cavity was cleared out for a distance of four inches and packed with bipp. The necrosed tissues, still attached to the stump, were dissected off daily, and on January 27th the patient was able to get out of bed and sit in a chair.

By March 2nd the stump was skinned over with the exception of about one square inch. The muscles had retracted, leaving exposed about four inches of femur, which I left with the idea that it would prove a useful lever for an artificial leg.

The patient was now able to get about the house rapidly on crutches, but had become depressed and had shown suicidal tendencies. He was therefore removed to a local mental hospital, where he remained for a year, returning home normal and cheerful, but with limited backward movement of the stump, in March, 1927. I now fitted him with an artificial leg, made to my design by the local blacksmith and the saddler, and weighing 2 lb. On this he has been able to walk a distance of a quarter of a mile. On November 19th he was shown at a clinical evening of the Rugby Medical Society, when the case was considered to deserve recording.

Three points are of special interest. (1) The injections of formalin could not be given nearer than three inches from the line of separation without causing pain or discomfort. (2) There was an almost total absence of decay from above the knee downwards, the skin being unbroken, illustrating the efficacy of the formalin. The only offensive smell was from the granulation tissue at the line of separation. (3) Though gas formation occurred in the thigh, the toxins absorbed caused a rise of temperature only on nine consecutive days during the eighteen weeks the dead limb was attached to the body.

The fleshy stump is six inches long. The bone, which up to now has been used as a lever when walking, is being eroded by granulations, and will soon separate spontaneously. Forward movement is free. Movement posteriorly stops short of the vertical.

I would welcome suggestions as to the best type of artificial leg, since his present leg will be useless when the bone separates.

Husbands Bosworth, Rugby.

J. A. NOBLE, B.M., B.Ch.

BLADDER CALCULUS IN THE MALE DUE TO A  
FOREIGN BODY.

THIS case is, I think, sufficiently unusual to be worth putting on record.

On May 15th, 1927, I was called to visit a young unmarried man. I found him suffering from acute epididymitis on the left side. I naturally suspected gonorrhoea, but the patient denied any possibility of infection. There was no urethral discharge, but the urine contained threads. A centrifugized deposit exhibited numerous pus cells and a mixed bacterial fauna, none of which appeared to correspond precisely with the gonococcus as regards shape, arrangement, or staining reactions. The patient made a more or less complete recovery following treatment by rest, bland

fluids, and mild urinary antiseptics. He returned to work in the third week of June.

At the end of September he again attended my surgery complaining of pain and difficulty in micturition. The urine was faintly alkaline, and contained blood and pus cells, with mixed cocci as before. He did not respond speedily to urinary antiseptics, so I decided to take a sterile specimen of urine for examination for evidence of tuberculosis. I endeavoured to pass a catheter for the purpose on October 10th, but failed owing to an obstruction in the neck of the bladder. Two days later he told me that he was passing urine more freely as the result of the instrumentation, and a few days later brought a few calcareous fragments that he had passed with his urine, with general relief of symptoms. On x-ray examination the shadow of a large calculus was seen to occupy the cavity of the bladder; the kidney areas were quite free. He was admitted to Ashford Hospital and, on November 4th, I removed a calculus from the bladder by the suprapubic route. It was bean-shaped, about 1½ inches long, ¾ inch in breadth, and 1/2 inch in thickness. I forwarded it to the county laboratory at Maidstone, and received the report that it consisted of a core of hard paraffin wax, surrounded by an envelope of phosphatic deposit. It would seem that the hard paraffin must have reached the bladder by the urethra. The calculus was returned to me in its divided condition, and showed clearly the wax centre with the surrounding envelope of phosphates, which is about 1/10 inch in thickness. The patient has made an uninterrupted recovery, and the calculus has been returned to Maidstone for preservation in the museum.

I am indebted to Dr. C. Ponder, who is in charge of the county pathological laboratory, for the assistance he has given and the interest he has taken in the case.

Ashford, Kent.

E. SCOTT, B.A., B.M., B.Ch.

### DIAGNOSIS OF GANGRENE OF THE SMALL INTESTINE.

The very interesting account and discussion published in the *BRITISH MEDICAL JOURNAL* of May 7th (p. 836) and June 4th (pp. 1033 and 1034) prompt me to send the following note of two cases I have come across during the last five years.

#### CASE I.

A well built man, aged 35, was admitted to the Jamsetji Jijibhoy Hospital, Bombay, in the wards of the senior physician, under whom I had charge, on January 1st, 1922, for severe pain in the epigastric region, which had been present for five days before admission. The abdomen was soft and there was no resistance to palpation anywhere. An enema resulted in partial elimination of the water; the suspected history of syphilis, helped by a blood examination in the absence of any leading signs and symptoms, tempted the diagnosis of "tabetic crisis." On January 2nd, at 5 p.m., the pain was worse, the abdomen had become distended, and the patient had begun to vomit; there was well marked resistance. I do not recollect whether he was passing flatus. Exploratory laparotomy was performed; a thrombosis in the superior mesenteric artery was found, and gangrene of the small intestine. The patient died on January 3rd in the morning. A *post-mortem* examination could not be obtained.

The point that I noticed about this case was the pain, in the absence of any definite signs, and a persistent slow pulse, varying between 50 and 60 a minute, as recorded by repeated observations, till the complicating symptoms just before operation, when the rate was faster.

#### CASE II.

A stout farmer, aged 35, came from up country on February 25th, 1926, while I was working as honorary physician, out-patients' department, in the Jamsetji Jijibhoy Hospital. He complained of pain in the abdomen of fifteen days' duration, worse after food, and distension of the abdomen, without vomiting or constipation. There was slight resistance to palpation in the umbilical region, and the pulse was slow. The general condition, the strength of the markedly slow pulse rate, and the severe persistent pain, in the absence of physical signs, induced me to diagnose the case as one of thrombosis of the superior mesenteric vein or artery. An exploratory laparotomy was performed, but the patient died the same night. *Post-mortem* examination revealed extensive gangrene of the small intestine, a firm thrombus in the superior mesenteric vein, extending up to the portal vein and its branches in the liver, causing a large infarct (6 inches by 4 inches) in the liver.

I do not know whether a slow pulse in the presence of the combination of symptoms referred to by writers to the *JOURNAL* of May and June may be of importance in deciding on the diagnosis of thrombosis of the superior mesenteric vein or artery.

P. V. GHARPURE, M.D.

Department of Pathology, Grant Medical College, Bombay.

## Reports of Societies.

### INTOXICATION AND ITS LEGAL CONSEQUENCES.

At a meeting of the Medico-Legal Society on January 26th a paper on drunkenness and civil and criminal responsibility was read by Mr. F. LLEWELLYN-JONES, coroner for Flintshire.

Mr. Llewellyn-Jones made a general survey of the subject of intoxication and its legal consequences as understood in English and other law. Dealing first with the effect of drunkenness upon civil capacity, he said that a contract made by a drunken person was voidable at the person's option, but a person who set up a plea of intoxication with a view to voiding a contract must satisfy the court that the other party was aware of his condition at the time the contract was made. With regard to injuries, if a person was so completely intoxicated that he could not appreciate the significance of what he was doing, it was reasonable to assume that he would be regarded in the same position as a lunatic. One was perhaps justified in laying down the rule that when a person was so far out of his mind—whether through insanity or complete intoxication—as not to know what he was doing, he could not be regarded as acting intentionally, and therefore in torts where intention was an essential element he was not under liability. On the other hand, it seemed only equitable that an inebriate who had caused injury to another person should make reparation, not as a punishment for inebriety, but as damages for the wrong done to the innocent, which damages, in the case of habitual intoxication, might well be exemplary. French juridical opinion took the view that a drunken person was not to be freed from the obligation to make good the damage, for it was his own fault that he had put himself into that state. The German civil code also took the view that the drunkard was responsible for damage, unless he had been brought into the drunken condition against his will, in which case the onus of proof that this had been so rested upon him.

On the question of the criminal liability of an intoxicated person for homicide, the famous case of Beard (*House of Lords*, 1920) was cited. Lord Chancellor Birkenhead, in dealing with that case, said that the earlier classical textbooks subscribed to the view that if a person, when drunk, killed another, he must suffer the ordinary penalty, for although he did it in ignorance, the ignorance was occasioned by his own act of folly. This view was later somewhat relaxed, though not according to any single or very intelligent principle. Lord Birkenhead laid down the following three rules: (1) insanity, whether produced by drunkenness or otherwise, was a defence to the crime charged; (2) evidence of drunkenness which rendered the accused incapable of forming the specific intent essential to constitute the crime should be taken into consideration with the other facts proved in order to determine whether or not he had intent; (3) evidence of drunkenness falling short of a proved incapacity in the accused to form the intent necessary to constitute the crime, and merely establishing that his mind was affected by drink so that he more readily gave way to some violent passion, did not rebut the presumption that the man intended the natural consequences of his acts. In the Beard case the indictment was wilful murder. The man, while drunk, had ravished a young girl, and in trying to stop her from screaming had suffocated her. The House of Lords held that drunkenness was no defence unless it could be established that the accused was so drunk as to be incapable of forming the intent to commit the rape, and as this was not alleged, the defence of drunkenness to the charge of murder—the murder having resulted from the rape by a succession of acts which could not be regarded independently—must fail.

The reader of the paper then reviewed the law in other countries. The British colonies followed generally the principle of the English courts. Under the Indian penal code a person who committed a crime under the influence of drunkenness, when the drunkenness was the result of his own fault, was in no better position than a perfectly

sober person, but the textbooks suggested that mental disease caused by voluntary intoxication would absolve from criminal liability. In the United States the courts had mainly followed principles not dissimilar from those laid down in the Beard case. One American legal writer pointed out that in insanity the law had to deal with a disease contracted against the will of the sufferer, whereas voluntary inebriety, leading to derangement of faculties, was not a disease, but something which might readily be prevented by the person himself. The French penal code made no reference to drunkenness, and French courts had formerly maintained the principle that drunkenness was no ground for exculpation; but a milder view had gradually prevailed, and some French juries had treated complete drunkenness as "passing dementia." German jurists had distinguished between accidental drunkenness produced by the artifice of another, fraudulent drunkenness, where a man deliberately made himself drunk in order to commit a crime or to afford him an excuse, and, finally, voluntary drunkenness. They distinguished also between stages of intoxication: (1) where consciousness was retained; (2) where consciousness remained, but the mind was clouded; (3) where there was complete intoxication, depriving a man of his reason and making him no longer a free agent. Rarely would a delinquent in the second category be treated as not responsible for his act, but almost always a delinquent in the third category. In the criminal code of the German Reich there was no express reference to drunkenness as a mitigating circumstance, but it might be considered as coming under the definition of a "state of unconsciousness or morbid disturbance of activity of mind, preventing free volition." Under the Austrian criminal code it was definitely laid down that no act should be regarded as a crime when the author was in a state of complete drunkenness, but the person committing the act should be punished for a serious police offence—up to three months' imprisonment, or six months' if he was aware of his liability to alcoholic excess. The condition of unconsciousness (*Bewusstlosigkeit*) contemplated by the German criminal code and other European systems was different from that state of complete insensibility which was the general connotation of the English word; it implied that the man acted unwittingly without conscious knowledge of the nature of his acts. The recent proposals of the Italian Ministry of Justice were interesting. A person who, in a state of complete drunkenness due to accident or *force majeure*, lost consciousness of his acts was held not to be responsible for the offence committed by him; otherwise drunkenness was held neither to aggravate nor extenuate an offence, unless a man had made himself intoxicated in preparation for his crime, or to furnish an excuse, in which case the drunkenness was an aggravation. One provision of the new code was that chronic delinquents should serve their sentence in a special establishment where they would undergo treatment for drunkenness.

In conclusion Mr. Llewellyn-Jones touched upon the problem of the intoxicated motor driver. One of the difficulties of the courts was that Parliament had refrained from giving any definition of drunkenness. An attempt was made in the proceedings on the Criminal Justice Bill, 1925, to incorporate words which would more clearly define the offence of being drunk—namely, "a state of intoxication whereby his capacity to act is impaired." In a South Australian Act the words were: "... so much under the influence of intoxicating liquor as to be incapable of exercising an effective control of such motor vehicle"; and in a Dutch law, 1924: "... so far under the influence of alcoholic liquor as not to be able to drive in a proper manner." A good definition was recently given by Judge Sturges, K.C.: "Where the skill and judgement normally required in the manipulation of a motor car are obviously diminished or impaired as a direct result of the consumption of alcohol." Some of the usually applied tests for drunkenness were often thought to be inadequate, particularly in the case of motorists who, while showing no signs of gross intoxication, might yet be unfit through alcohol to be in charge of a car. Finally, he quoted with approval some remarks from Sir James Purves-Stewart's lecture before the Society for the

Study of Inebriety,<sup>1</sup> to the effect that drunkenness was not a simple clinical entity like a broken bone or a consolidated lung, and that the important point was not whether a man could perform certain tests correctly, but whether he was in a fit condition to pursue his ordinary daily avocation. The primary duty of the medical examiner as well as of the magistrate was to satisfy himself as to whether there was impairment of the power to drive with reasonable care.

### LIFE ASSURANCE IN THE TROPICS.

At a meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on February 2nd, at 8.15 p.m., Dr. ANDREW BALFOUR in the chair, a discussion on life assurance in the tropics was introduced by Dr. J. F. C. HASLAM, assistant director of the Bureau of Hygiene and Tropical Diseases.

Dr. Haslam said that the chief interest in the subject of life assurance in the tropics lay, for him, in the attempts which had been made to determine not only the amount of increased risk involved in tropical residence, but also the factors in its production. Those interested in forwarding the policy of a White Australia had maintained that a hot, humid climate had no detrimental effect *per se*, and that the harmful results arose from disease and faulty habits. He did not agree with this view, and found the arguments of Cilento and others unconvincing. Attempts by Sundstroem and others to clear up the matter by experiment had not helped much; this work was considered inconclusive by Halliburton. Referring to the confident claims by Sir James Barret and others that the actual experience of Northern Queensland had proved the practicability of white settlement there, Dr. Haslam held that a much longer period must pass than had yet elapsed before it could really be certain that no deterioration of the stock had taken place. He concluded by giving examples of the extra premiums charged by certain London insurance offices for various parts of the tropics. The great variation between country and country and between company and company indicated to him that neither the insurance offices nor their medical advisers had as yet any very clear ideas of the amount or cause of risk to life and health involved in tropical residence.

Mr. H. E. RAYNES, F.I.A., stated that a constant difficulty confronting actuaries in assessing tropical premiums had been the lack of reliable statistics; crude death rates were almost valueless, and the tendency had been for offices to rely on their own very limited experience, thus causing a lag between the actual mortality current at a particular date and the premium charged. He favoured the classification of the world into normal, sub-tropical, and tropical zones in dealing with the case of European peoples. A mixed racial population presented special difficulties, since mortality was a factor of race as well as climate. In various West African districts the mortality was 10.3 per cent. in 1886; in 1911 it had fallen to just over 1 per cent. It was unreasonable to suppose that this improvement was confined to West Africa alone; he had computed some figures for that country during the period 1921 to 1924 which showed that the actual death rate was 1.14 per cent., compared with the English death rate of 0.80 per cent. (based on the No. 8 English table). The mortality during the first few years of tropical residence was higher than later. Mr. Raynes's investigations had shown that a constant addition of under 0.6 to the percentage rate of mortality as shown by the new English life table would adequately cover the excess mortality in West Africa. This would mean the addition of from 4s. 10d. to 7s. 5d. per cent. to the annual premium charged, and a policy from a first-class office could be now obtained with an addition of not more than 10s. to cover West African residence. In East Africa the high lands did not appear to be detrimental to health, but the coastal plains and lake margins corresponded to West African conditions. In Mr. Raynes's opinion the factors governing tropical mortality were race, geographical surroundings, political and social administration, and occupation. He showed graphs illustrating the fall in mortality and sickness in West Africa within recent

years, and tables illustrating the classification of the world into zones for insurance purposes.

Sir LEONARD ROGERS compared the results of over 1,600 necropsies in Calcutta with over 1,000 in London. In Calcutta about one-third of the deaths were due to purely tropical diseases, such as malaria, kala-azar, cholera, and dysentery. There were relatively few cases of cancer in India, because the normal length of life was much shorter than in Britain. Tuberculosis, on the other hand, was twice as common, and both respiratory and digestive diseases were much more frequent. Septicaemic diseases and tetanus were also very high, although, since the introduction of serum treatment, the latter had been much reduced. Typhoid fever also was very common. It was of interest to observe that tuberculosis—especially pulmonary tuberculosis—caused a higher mortality than any of the purely tropical diseases; Sir Leonard Rogers attributed its prevalence to the habits of expectoration and the contamination of milk in the streets. While lobar pneumonia was often seen, broncho-pneumonia was rare. Heart diseases were half as common as in London, and rheumatic endocarditis was quite absent, although streptococcal infections were otherwise frequent. Aortic valve disease was common, although mitral was rare—the reverse of the position in England. Gastric ulcer was unusual in India, but cirrhosis of the liver was common. It was not alcoholic in its origin, and was probably secondary to dysentery.

Mr. J. A. CALDER questioned if heat without humidity had a very adverse effect on men in the tropics. He had noticed that in Africa, where the climate was dry, the effects were much less marked than in places where it was wet. Dr. W. NICOLL said that tropical Australia had more tolerable conditions than elsewhere in the tropics, and that the population included few others than Anglo-Saxons. It could not be compared with other tropical countries, but only with Europe and the rest of Australia. Policies were not loaded there. Overcrowding was absent, even in the towns, and there was only one person to eight square miles. The population, moreover, was selected and there was no unemployment. Accordingly there was no reason why insurance should be dearer than elsewhere in Australia. None of the classical tropical diseases was present, and the chief causes of death were diseases like dengue. The expectation of life was increasing there, and the effective working age period was greater than in any country in Europe. Mr. R. E. UNDERWOOD discussed the business aspects of insurance, and said that increased premiums might be deliberate in order to exclude insurances which any particular office considered to be undesirable.

Dr. H. STANNUS thought that individuals were not always acclimatized on residence in the tropics; on the contrary, there was often a general deterioration throughout service. Comparison of tropical countries should not be by latitude but by isotherms, humidity, or some such feature. Countries could not be classified by lists, and each must be considered on its merits. It was necessary, however, for an insurance office to use an average which would deal hardly with some policies and favourably with others. Dr. DREW SHANN said that the real reasons for the high death rate in West Africa were still obscure, but he believed that neurasthenia and social conditions were most important. He personally had found that the climate of northern Nigeria, with its great extremes of day and night temperatures, was agreeable, but trying; in the Cameroons, an almost uninsurable district with a very small range of temperature and great humidity, life was much less exacting. Dr. CHRISTOPHERSON thought that both humidity and heat were very trying in the tropics, and that frequent holidays were necessary for white men employed abroad.

#### UTERINE SARCOMA.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on January 20th, the president, Mr. COMYNS BERKELEY, in the chair, Mr. W. GILLIATT showed a specimen illustrating sarcoma of the uterus.

Mr. Gilliatt said that the specimen was obtained from a patient, aged 27, whose symptoms had only lasted one month. She had a sudden attack of acute abdominal pain

ten days before operation. The physical signs were unusual, in that the swelling was found rising out of the pelvis to within one inch of the umbilicus; in the right lateral and posterior fornix was another swelling, soft and almost cystic. A subtotal hysterectomy was performed and the right tube and ovary were removed. She was now in excellent health, and nothing abnormal could be detected on examination. The microscopic sections show the characters of a myosarcoma.

#### Difficult Labour in an Aboriginal.

Professor J. B. CLELAND (University of Adelaide) sent a short communication entitled "Difficult labour in a pure-blooded Australian aboriginal woman." This was an account of the whole process of labour. The first stage was normal, the second was unduly prolonged, the child lying in the left occipito-posterior position. The head descended to the plane of the ischial spine, but further progress was impossible. Under anaesthesia the position was converted into a left occipito-anterior, and great difficulty was experienced in delivering the head by axis traction forceps. The shoulders were only delivered by extreme traction, and there was similar difficulty with the breech. The placenta was retained for thirty-five minutes and was removed manually. After labour the pelvis was examined, and was thought to be of the funnel variety. It was also slightly generally contracted. The child was unusually large, weighing 12½ lb.

#### Albuminuria during Pregnancy.

Mr. G. F. GIBBERD read a paper on the results of albuminuria occurring during pregnancy, with special reference to the relation between pregnancy kidney and chronic nephritis. This paper was the result of investigations of seventy-eight patients at the post-natal clinic of the maternity department at Guy's Hospital, forty-three of whom were examined at intervals greater than six months from delivery. Mr. Gibberd concluded that albuminuria of pregnancy recurred in subsequent pregnancies with much greater frequency than was usually stated. He considered that this pointed to permanent renal damage as a result of the primary albuminuria. The evidence showed that chronic nephritis might arise *de novo* as a sequel to pregnancy kidney, and Mr. Gibberd added that he thought the most delicate test of the renal function in a patient who had had a pregnancy kidney was a subsequent pregnancy. He had found permanent renal damage in over 50 per cent. of his cases. He did not believe it possible to say that there was no danger in an albuminuria occurring during pregnancy, and he advocated abolishing the term "functional albuminuria of pregnancy." He also concluded that induction for this condition was commonly postponed too long, and that the mere avoidance of eclampsia was not an obstetric triumph. As a further argument in favour of early induction he instanced the frequency with which the foetus was macerated in these cases.

#### INFLUENCE OF STATISTICS ON MEDICAL PRACTICE.

A MEETING of the Liverpool Medical Institution was held on January 14th, when the president, Dr. J. C. M. GIVEN, was in the chair.

Mr. FRANK JEANS read a note on statistics, with some observations, and remarked that some observations were more valuable than statistics—as, for example, Mr. Paul's statement that a woman aged 75 was not so old as a man of the same age from the point of view of a major operation. The influence of statistics on an operator's mentality was indicated by the subconscious rejection or inclusion of certain cases which might affect his mortality rates. Mr. Jeans thought that if a case of appendicitis was treated medically and the patient died because the condition was really one of internal strangulation, it should be recorded as a death from appendicitis treated medically; a death from pneumonia treated by operation in mistake for appendicitis should figure as a death from appendicitis treated surgically, because the patient was actually, if not statistically, dead. Now that much surgery was being performed by practitioner-surgeons, it must be obvious

that specializing surgeons were getting an increasingly high percentage of difficult cases, and therefore, if their mortality figures were as high as they were fifteen years ago, this was no cause for depression. The practitioner-surgeon, who often admitted that he only dealt with the easy cases, was more selective than the "pure surgeon" was allowed to be, and therefore comparisons between the two classes of mortality were impossible. The pure surgeon, especially when successful, was willing to have the most difficult cases sent to him.

#### *The Detection and Care of Rheumatism in Childhood.*

Dr. A. DINGWALL FORDYCE, in a paper on rheumatism in childhood, said that detection of the frank, classical type of acute rheumatism was simple, but active rheumatism, endangering the heart, was often present in the absence of striking symptoms. The fundamental inclination towards infection was a diathetic peculiarity which might be determined before or after birth, and lead ultimately to the exhibition of rheumatic symptoms as a result of endogenous infection by probably varying organisms of a similar group. The main aim must be to prevent the development of such a constitutional tendency as would lead to a favourable field for bacterial infection. During 1927 out of 213 cases of rheumatism one child had died from rheumatic heart disease. In 71 cases the heart was permanently injured without doubt when the child was first seen, and at the end of the year 97 children disclosed permanently damaged hearts. In 31 cases the condition of the heart was doubtful, and in 84 cases there was no cardiac affection. Rheumatic nodules were noticed in 3 cases. The "intelligence quotient," taken during the quiescent or convalescent stage, was usually well above 80, the deficiency being mainly scholastic. The essence of correct care was physical and mental supervision for a prolonged period. For the poorer classes six months in a county hospital with a school such as that at Heswall proved very valuable after the initial condition had been dealt with in the city hospital, but for effective results a further prolonged period in a residential school was often essential.

### THE OVER-SENSITIVE CHILD.

A MEETING of the Section of Medicine of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on January 20th, with the president, Dr. G. E. NESBITT, in the chair.

Dr. B. CRICHTON, in a paper entitled "The sensitive child," pointed out how much a very sensitive disposition influenced behaviour, and might produce syndromes capable of being mistaken for the symptoms of disease. Much depended on the wisdom of those in charge of such children; for instance, abnormal behaviour in a sensitive child was often the result of the follies or neuroses of the parent or nurse. Sympathetic handling was essential, and encouragement rather than repression was the clue to managing most of the problems of difficult children. Many children laboured under the disadvantage of being forced to attend a school where education was carried out in surroundings and under conditions prejudicial to good health. He urged that medical men in Dublin should unite to make educational authorities see the harm done by the present system. Hours were long, the lunch interval badly chosen, lavatory accommodation defective, medical inspection wanting.

Dr. M. F. O'HEA agreed that the sensitive child was a definite entity. Every child was different, and he felt that to try to make children plucky by holding up to them the pluck of other children was a great mistake. The question of giving the children their principal meal at the proper time in the middle of the day was vexing the minds of the educational authorities at present; some schools insisted that the children should have dinner at 1 o'clock, and stopped school from 1 to 2 o'clock for this purpose. He thought this was bad for the children's digestion, as it meant that they had to eat their meal too hurriedly. One of the most important things in the management of children was being careful about the people who looked after them.

Dr. V. M. SYNGE thought children went to school at far too early an age, and learnt a lot of things by routine,

instead of reasoning them out. He felt that the so-called increase of education in Ireland by compelling attendance at the national schools was not an unmixed blessing. He had seen children in quite an advanced stage of tuberculosis who were sent to school every day, as their parents were afraid that if they did not send them they would be smudged. The national schools at present were far too crowded; in many of them there were 150 children in about three rooms, with only three teachers.

Dr. N. FALKNER asked if most of the children seen by Dr. Crichton were children who had had some definite organic lesion, or in whom diet had been faulty, and if the majority of them were children who had not been breast-fed. If they were children who were not breast-fed he thought that cases were more likely to occur in private practice than in hospital practice.

Dr. R. J. ROWLETTE referred to the necessity for an altered school hygiene, and said it was a pity that the enforcement of attendance at schools should have anticipated the establishment of a proper system of medical inspection of schools. Referring to the sensitive child, he said that while individual attention was necessary in the diagnosis of the condition, he thought it might be carried too far in the treatment of the child. He felt that the concentration on itself by a child which might take place if individual attention was pressed too far was unhealthy for the child.

Dr. L. ABRAHAMSON agreed that one of the most difficult points in dealing with the nervous child was the comparatively unknown factor represented by the nurse, who was interposed between parents and child. In some cases it was as necessary to study the parents and the nurse as it was to understand the child. He agreed that school hours were too long, and thought it unfair that the hours should be longer in national schools than in private schools.

The PRESIDENT said that he could not imagine anything worse than a child who was not sensitive, or an adult either. He thought that Dr. Crichton should have entitled his paper "The hypersensitive child." One of the most important influences in the bringing up of children was the nurse. He referred to the factor of heredity; which he thought played a great part in the sensitiveness of children, and said that nowadays in cases of extreme naughtiness in children the question of encephalitis lethargica was worth going into, for children who had over suffered from this disease, even slightly, were very liable for some time afterwards to be naughty purposely.

Dr. CRICHTON, in replying, said that when talking about sensitive children, he really had in mind hypersensitive children. The ordinary child wanted to be constantly doing something, and he thought that care should be taken to study its favourite pastimes and habits. He felt that the education of nurses for small children had not really been given enough thought. A person needed to be born a nurse: it was really not possible to teach a person to be one. He thought that enough interest was not taken in the teaching of children, and that the preparatory school was more important even than the public school, as in the first five years a boy could be either made or marred. He had not found much difference between breast-fed and bottle-fed children. By over-treatment a child could, of course, be made more hypersensitive. He thought that the principal meal should be between 1 and 1.30 o'clock, and not as late as 2 or 3 o'clock, and that the interval in the middle of the morning given in most schools was not long enough.

#### *Psychoneuroses.*

Dr. J. H. POLLOCK read a paper on a case of psychoneurosis. In describing the clinical history he pointed out the importance of the time factor. In the case he described the psychological disturbances came on first some considerable time after the shock to which they were due, and roused up buried fears dating back to a much earlier period. Moreover, it was important to remember that recovery was bound to be slow, and attempts to hurry the process were comparable to the "meddlesome midwifery" of which complaint was made at times. Simple analysis might help the physician to understand the details of his case, but it was a grave mistake to interest the patient in the process or present it to him as a means of treatment.

The psychoneurotic tended to be subjectively minded; and the object of treatment should be to make him objectively minded; to interest him in his own mental processes was to do the reverse.

The PRESIDENT said that repression was now admitted to be one of the most important factors in mental upset. He thought that the heredity aspect must also be present. Referring to the endocrine basis of these disturbances, he felt strongly that these cases were all due to endocrine disturbance; even more attention should be focused on these glands than was being done at present. The classification of these cases seemed to be quite hopeless, but he did not think that classification would help much unless some light was thrown on their etiology.

Dr. ABRAHAMSON said that he saw a number of patients rather similar to the one described by Dr. Pollock, and he thought that in cases such as these it was important to work up the details as Dr. Pollock had done, but in a general practice this was impossible, and he thought that they should only be dealt with by a man who had the time to go into them thoroughly. He referred to the line of demarcation between the extreme psychasthenic patient and one definitely mental. He believed that satisfactory classification of these cases would be impossible until more light was thrown on their etiology.

Dr. ROWLETTE thought that in these cases the most important point was not classification in regard to treatment, but in regard to prognosis. The question was, When should the line be drawn between a case such as the one described by Dr. Pollock and a case which should be certified? Many of these patients got seriously depressed, and it was in the depressed patient who was not actually insane that there was the greatest danger of suicide and the possibility of not putting the patient under restraint soon enough. In a great many of these cases the condition seemed to arise out of a conflict which went on for some time, and this conflict was generally between one of the primal motives in human beings and that of moral restraint. He thought that in most of these people the unfortunate subject took refuge in drugs as a method of preventing loss of self-control, which he would do if left to his own exertions. He thought it might be assumed that the endocrine secretions were definitely associated with certain emotions. These conditions had to be looked on as having their origin both in the mental substructure and in the physical substructure, and it was impossible in any case to separate one entirely from the other.

Dr. M. F. O'HEA did not think that cases of severe neurasthenia were nearly so common now as in the previous decade.

### VULVO-VAGINITIS IN CHILDREN.

At a meeting of the Edinburgh Obstetrical Society on January 11th, with Professor R. W. JOHNSTONE in the chair, a paper was read by Mr. DAVID LEES on vulvo-vaginitis, in which he analysed the cases which had come under his observation in a period of five years—1922-27.

Mr. Lees dealt with a total of 146 cases, which were divided into the following age groups:

0 to 1 year	...	...	7.4 per cent.
1 to 5 years	...	...	39.2 "
5 to 10 "	...	...	44.9 "
10 to 15 "	...	...	8.4 "

He said that the incidence of vulvo-vaginitis in Edinburgh had been augmented by a recent epidemic in a children's institution, in which the disease had spread rapidly and proved to be very contagious. In the largest number of cases, 40 per cent., the source of the infection could not be ascertained. In 13 per cent. of the cases the patients were reported to have been assaulted, but in only a very small proportion of these cases was this proved; 15 per cent. of the cases were epidemic in origin, and in 32 per cent. the infection was traced to others in the family. The symptoms and signs of the disease were described, and attention was drawn to the frequency (99 per cent.) with which the urethral canal was involved in acute cases. Mr. Lees insisted that every vaginal discharge in children must be looked on with suspicion, and treated as if of gonococcal origin, until at least three bacteriological tests, performed under conditions favourable for the detection

of the gonococcus, had proved negative. In chronic cases repeated films and cultures were necessary, and in resistant cases direct films or cultures must be taken from the cervix. In 73.7 per cent. of the cases gonococci were found, in 6.6 per cent. gonococci and other organisms, and in 19.7 per cent. secondary organisms only. In acute cases the gonococcus was demonstrated in over 98 per cent. of cases. The more acute signs of disease disappeared rapidly with treatment, but the parents should always be warned that a long time was required to eradicate the disease, and that relapses were apt to occur unless the patient was kept under treatment. Hospital treatment and isolation of the patient from other children were advised wherever possible. The chief therapeutic measures recommended were hot antiseptic and alkaline hip baths with daily lavage of the vagina and urethra. In older children the vagina was dried by swabbing through a speculum and the parts were dusted with dermatol powder; in younger children, when a speculum could not be introduced through the hymen, instillations of an antiseptic dissolved in glycerin were employed. The antiseptic preparations recommended were 1/4 to 1 per cent. picric acid in glycerin, 1/4 to 1 per cent. silver nitrate in glycerin, and 1/4 to 1/2 per cent. chloramine-T in glycerin. The instillations were supplemented by the use of small medicated bougies of these and other substances. If it was not possible to irrigate the urethra small urethral bougies, with ehlretone added to ease the pain, were inserted daily. Repeated changing of the antiseptic was advised, and it was recommended that in every case the vulvar surface should be left as dry as possible by dusting it with a compound dermatol powder. Efficient treatment depended more on the meticulous care with which it was applied than on the medicament used. In every case it was essential: (1) to establish good drainage from the urethra, vulva, and vagina; (2) to produce a slight hyperaemia of the infected parts by hot hip baths and hot vaginal douches; (3) to use a sterile all-glass catheter with lateral perforations in douching so as to spread the antiseptic over the vaginal wall during the douche and prevent the infection being carried to the cervix; (4) to dry the parts subsequent to douching, or alternatively treat the vagina with instillations of an antiseptic solution in glycerin; (5) to treat the urethra in every case; (6) to examine and treat the rectum if infected; (7) to prevent the child from conveying the infection to others and to its eyes. Adjuvant methods of treatment were used in both acute and chronic cases, and of these detoxicated and autogenous vaccines had proved the most serviceable. The child tolerated and responded well to vaccine therapy.

In the series of cases reviewed the following complications arose:

Gonococcal infection of the eye	...	8.3 per cent.
Infection of the Fallopian tubes and pelvic peritoneum	...	5.5 "
Infection of the rectum	...	2.7 "
Non-specific ulceration of the vulva	...	1.8 "
Acquired syphilis of the vulva	...	1.8 "
Cystitis	...	0.9 "

No cases of arthritis were met with, but coincident syphilis occurred in 7.5 per cent. of all the cases. In making a diagnosis of cure it was essential to observe cases over long periods, and to examine repeated films during this period of observation. The standard of cure aimed at in every case should be: (1) Clinical cure and no sign of clinical relapse after suspending all local treatment. Local treatment must be continued for at least three weeks after apparent clinical cure. (2) Bacteriological cure in three successive smears taken at intervals of one week during treatment, and in three subsequent weekly tests taken after suspending treatment. (3) Clinical and bacteriological tests at intervals of one month over a period of three months subsequent to the attainment of (1) and (2). (4) If there was any doubt as to the clinical condition or as to the bacteriological reports, administration of a provocative vaccine and a repetition of the tests both by direct film and by culture were indicated. (5) If there was neither clinical nor bacteriological evidence of disease during a period of three to four months after cessation from all treatment the case might be considered cured. In trying to attain this standard the following

results were obtained in the series of 146 cases reported. The average duration of treatment and tests for cure of gonococcal cases in those completed (87 cases) was seven months. The average duration of treatment and tests for cure of vulvo-vaginitis cases not proved gonococcal (21 cases) was two months. Thirteen cases which were still under treatment but presumed cured had been under treatment and tests for cure for a period of five months; eighteen cases were under active treatment with infection still present. Seven patients had defaulted while still showing signs of infection.

#### *Puerperal Haemorrhage.*

Dr. KENNEDY then gave clinical notes of three cases of puerperal haemorrhage. These cases were of interest as the bleeding was very severe and did not begin until after the tenth day of the puerperium; the dates of occurrence being the tenth day, fourteenth day, and sixth week after delivery. There was also no definite cause found for the haemorrhage, even after thorough examination under chloroform and enretage. In each of the cases, however, a retroversion was present, which was the more interesting as on dismissal from the maternity hospital in all cases the uterus was anteverted. In no case was there any apparent infection present during the puerperium. In two cases the mother was not nursing her baby, and therefore the haemorrhage might be the return of an early menstruation. Dr. Kennedy was doubtful as to the cause of the haemorrhage, but since retroversion was common to all, he thought that it must have something to do with the haemorrhage. He could, however, find no record anywhere of a simple retroversion in the puerperium causing so severe a haemorrhage.

#### FORFARSHIRE MEDICAL ASSOCIATION.

At a meeting of the Forfarshire Medical Association on December 15th, 1927, at University College, Dundee, the president, Dr. T. F. DEWAR, in the chair, Dr. W. E. FOGGIO read a paper on hereditary haemorrhagic telangiectasia, and added a new case to the forty recorded in the literature.

Dr. Foggio said that the essential features of the condition were an hereditary tendency to epistaxis and telangiectasis. His patient, a woman now aged 42, had a typical family tree, and he had been able to trace the condition back through five generations. All the other affected members of the family had both the epistaxis and the telangiectasis, but in his patient these signs were atypical. The only telangiectasis visible was one on the lower lip, which had been there for as long as she could remember. An unusual feature, and, so far as he knew, one never noted before in this condition, was the occurrence of haematuria, presumably from a telangiectasis in the urinary tract; the urine contained blood and albumin, but no casts. The blood film was normal. Before the onset of an attack of haematuria she occasionally had epistaxis with headache. There was no evidence of renal or cardiovascular disease, and no suspicion of tubercle or tumour. He suggested that this case might form a link between hereditary haemorrhagic telangiectasia and essential haematuria of hereditary type.

Dr. ARTHUR MILLS read notes on a case of recurrent spontaneous pneumothorax. A man, aged 21, who appeared in perfect health, complained of pain in the left side of the chest and breathlessness on exertion. The pain had come on suddenly twelve days previously, accompanied by a feeling of suffocation and faintness; he had had several similar attacks before. A diagnosis of pneumothorax on the left side with displacement of the heart was confirmed by x-ray examination. He made a complete recovery, but one year later a right pneumothorax was found. Recovery from this was followed in a few days by another right pneumothorax, from which he again made a complete recovery. There was no evidence of disease of the lungs, no indication of pleural adhesions, and no history suggesting former tuberculosis. Radiograms of the chest at various periods after an attack were shown by Dr. G. H. S. MILLS.

Dr. J. S. Y. ROGERS read notes on a case of chloroma in a female child aged 11 months, which came under observation because of proptosis of both eyes. The blood picture

was that of lymphatic leukaemia, the leucocytes rising eventually to 65,000 per c.mm. (large lymphocytes 38 per cent., small lymphocytes 57 per cent.). Multiple tumours of the skull appeared later. A post-mortem examination could not be obtained.

Mr. JOHN ANDERSON gave a lantern demonstration to illustrate the effect on the tissues of the are electrode in surgical diathermy. He exhibited photomicrographs from sections taken along the line of incision in amputation of the breast and in excision of a part of the lip. The sections showed on the surface a discontinuous delicate film, which might be coagulum, and beneath this a narrow zone, about 0.1 mm. in depth, where the cells were altered and desiccated. Mr. Anderson also described briefly his technique in surgical diathermy.

#### DIGESTIVE FACTORS IN ROSACEA.

At a meeting of the London Association of the Medical Women's Federation held on January 24th, with the president, Miss BOLTON, in the chair, Dr. SYRIL R. EASTWOOD gave an address on the results of an investigation into the gastric secretion and other digestive factors in rosacea.

Dr. Eastwood defined rosacea as essentially a chronic congestion of the facial skin, affecting mainly the central two-thirds of the face and leading to permanent vascular dilation of this area. Papules and pustules, eczematous scaling, ocular lesions, hypertrophy of the subcutaneous tissues leading to rhinophyma, though seen in varying degrees in the clinical picture, were to be regarded as complications of the underlying vascular condition. The eyes were affected far more frequently than appeared from the literature on skin diseases. Since Ait described a case in 1864 there had been constant reports of cases in ophthalmological journals, and Dr. Eastwood explained this discrepancy as being due in the first place to rosacea keratitis occurring often in mild forms of facial rosacea, and secondly to the greater importance attached by patients to a condition affecting their eyesight than to their appearance. It was not until the recognition, even now not general, of the relationship between the two that the cases had been freely interchanged between the eye and skin departments of hospitals. Dr. Eastwood said she had been led to rosacea by her interest in the digestive system, and had hoped to obtain a series of patients with achlorhydria or extreme degrees of hypochlorhydria to observe, as Barber and Ryle had reported this anomaly of gastric secretion as present in 58 per cent. of the rosacea cases examined by them. In a series of over 50 cases of rosacea, 7 of which had ocular complications, Dr. Eastwood had found digestive disturbance present in about 90 per cent., and that it was nearly always "functional" in the sense that no organic lesion of the gastro-intestinal tract could be demonstrated. Fractional test meals had been given to all patients, and 9 per cent. had achlorhydria, 24.5 per cent. hypochlorhydria, and 15.5 per cent. low normal curves, thus agreeing very closely with Brown's results in a similar series published in 1925. These results corresponded closely with those found in chronic arthritis and chronic cholecystitis by other observers. Flatulence, constipation, flushing after meals, and capriciousness in diet had been the commonest symptoms complained of. From the x-ray examinations made in many of these cases it appeared that some degree of hypotonicity was common, though by no means universal. Marked dislike of meat had not been found correlated with low acid secretion, and had occurred equally with high normal and hyperchlorhydric curves—a point of much physiological interest. Focal sepsis had been found in many cases. Dysfunction or disease of the female genital organs had been found in only a few cases, and as these had been cervicitis they fell into the focal sepsis heading. The majority of the patients had low systolic blood pressures. Whatever the type of digestive disturbance, its effective relief had been accompanied by relief of the rosacea. Hydrochloric acid in drachm doses with meals had had an almost magical effect in the patients with low or absent acid secretion; but it had also proved useful where no deficiency had been shown. Carbohydrate excess in diet had been a fairly constant finding, and its correction a strong factor in successful treatment.

## Reviews.

### COMPARATIVE ENDOCRINOLOGY.

DR. L. T. HOGBen's book *The Comparative Physiology of Internal Secretion*<sup>1</sup> is a distinguished contribution to the new series of Monographs on Comparative Physiology, published by the Cambridge University Press. The subject of the chemical co-ordination of function is one of quite recent growth in comparison with that of our knowledge of the complementary phenomenon—the nervous co-ordination of function. Nevertheless, the growth of endocrinology has been rapid, if sometimes impatient. Now, as the author points out, the practical justification for comparative physiology resides in the fact that some animals provide far more accessible material for the solution of a particular problem than others. This has proved very true in respect of the physiology of the ductless glands, and it has undoubtedly been the comparative point of view which has disciplined the less cautious claims in this field.

In a field in which terms are apt to be used with little discrimination, Dr. Hogben is wise to define his subject with precision. He regards an internal secretion or hormone as "a substance liberated into the blood stream by the specific activity of a particular structure, and which there is capable of evoking response in tissues remotely situated." It is no economy of hypothesis to extend the term, as some writers do, to include any physiologically active cell constituent, such as choline or even carbon dioxide. The argument of the monograph, then, is directed towards establishing the functional importance of internal secretion as a part of the mechanism of co-ordination. The various chapters deal with neuro-muscular co-ordination and the suprarenal, with the chromatic function in relation to the suprarenal and pituitary, with secretory processes and the activity of the intestine and pituitary, with vasomotor regulation by the pituitary, with metabolism as affected by the pancreas, thyroid, and parathyroids, and with developmental processes in relation to internal secretions of the thyroid and pituitary. Discussion of the internal secretions of the reproductive organs is omitted with intention. It appears that a monograph upon this particular subject will shortly be added to the series. It suffices to add that the literature of comparative physiology is carefully sifted, that the discussion, though severely critical, is considerably performed, and that recent work is given generous space and careful appraisal. The book is a contribution of real distinction to the literature of endocrinology.

### THE "ACUTE ABDOMEN."

WE have received for review three books on the "acute abdomen," by Mr. ZACHARY COPE.<sup>2</sup> The first deals with diagnosis, the second with treatment, and the third with clinical research in acute abdominal disease. The books are of uniform size and price, and belong to the Oxford Medical Publications.

The first volume, *The Early Diagnosis of the Acute Abdomen*, is in its fourth edition, and this must not be judged by the rather forlorn paragraph on mesenteric thrombosis and embolism to which attention is drawn in the preface as the chief addition to the present issue. The volume is still the very valuable, lucid, compact account of the common abdominal emergencies that must appeal to every student and young medical man. Probably the pages have served as the basis of many a clinical lecture, and no surgeon, however experienced, will be the worse for reading it; few will study it carefully without finding something of value to them. We are inclined to predict that the fourth edition will not be the last.

The volume on *The Treatment of the Acute Abdomen*

<sup>1</sup> *The Comparative Physiology of Internal Secretion*. By Lancelot T. Hogben, M.A. Cantab., D.Sc. Lond. Cambridge Comparative Physiology. London: Cambridge University Press. 1927. (Demy 8vo, pp. 138; 37 figures. 10s. 6d. net.)

<sup>2</sup> Three Volumes by Zachary Cope, M.D., M.S., F.R.C.S. (1) *The Early Diagnosis of the Acute Abdomen*. Fourth edition. Pp. xiv + 237; 20 figures. (2) *The Treatment of the Acute Abdomen*. Pp. xvi + 238; 146 figures. (3) *Clinical Research in the Acute Abdomen*. Second edition. Pp. xvi + 238; 146 figures. Oxford Medical Publications, London: Milford, Oxford. 8vo. 10s. 6d. each volume.)

must be appraised according to its intentions, "to help those doctors who are not much practised in abdominal surgery, but who may be called in an emergency to operate upon an acute abdominal condition." The claim that "if the technique advised be followed carefully a very large proportion of successful cases can be assured" is likely to be made good, for while probably no surgeon will agree with every dictum, such criticism as may be offered here deals with minor matters. Clearly it is necessary in such a book to advocate caution, but in the matter of dosage of morphine (gr. 1/6) and of medinal (gr. 2) the caution seems perhaps excessive. Jejunostomy has certainly proved useful in skilled hands, but it must be very seldom called for, and it has disadvantages in the hands of the inexperienced. Is it wise to advocate the use of intravenous ether by those for whom, avowedly, the author writes? Is it likely that Turkish sponges will be adequately sterilized? Is it worth while mentioning a procedure for which the author (p. 67) "can hardly imagine its necessity"? The plan of shortening the mesosigmoid by mattress sutures when operating for volvulus is hardly to be recommended to the tyro. Half a dozen other such comments might be made, but their trivial character bears witness to the essential soundness of the teaching and the clarity of the directions. This is a valuable book, adapted to its purpose; it does not shirk difficulties.

In Mr. Cope's third volume, *Clinical Researches in Acute Abdominal Disease*, is to be found evidence of the painstaking work that has gone to the successful production of the seemingly simple books reviewed above. The most important new feature in this, the second edition, is the study of "shock" embodied in the author's Hunterian Lecture. He elaborates the observation that shock may be present and manifested by other signs, with a blood pressure still high; so long, that is, as the fall in circulating blood volume can be compensated by vasoconstriction. His thesis of "dissociation of symptoms" in shock is amply illustrated by case records, and the presentation of it is convincing because it appeals to what is common experience. His "definition" of shock, however, is not much more successful than its predecessors: definitions should not need explanation.

### PATHOGENIC MICRO-ORGANISMS.

SINCE the first parts of the third edition of KOLLE and WASSERMANN's handbook of pathogenic micro-organisms<sup>3</sup> were reviewed in our issue of May 7th, 1927 (p. 839), several fasciculi, forming parts of several volumes, have appeared. These contributions, which follow the lines adopted in the earlier fasciculi, are admirable reviews of the subjects they deal with, and contain lengthy bibliographies. A mere enumeration of some of the principal contents of the various parts is all that can be attempted here; but this will, we hope, serve a useful purpose by providing fingerposts for those to whom the work is addressed.

Part 12 of volume i contains the final sections of Gotschlich's article on the general morphology and biology of pathogenic micro-organisms, a summary of the researches carried out on the bacteriophage by R. Otto and H. Munter, and shorter articles on the nature of infection and on mixed and secondary infections by A. Seitz. Part 6 of volume ii contains four papers on immunity: on active immunity by M. Fickler, on the production of antibodies by R. Bieling, on the concentration of antibodies by St. Bächer, and on the value of antisera by R. Otto and H. Hetseb. Part 5 of volume iii contains articles on serum therapy against snake, scorpion, and spider venoms by R. Kraus, on researches on animal venoms by H. Sachs, on plant toxins by M. Jacoby, on hay fever and asthma by G. L. Hoffmann. Part 8 of volume iv contains articles on the pseudo-tuberculosis of rodents by K. Poppe, on the staphylococci by M. Neisser, and on undulant fever by A. Lustig and G. Verroni; and Part 11 of the same volume

<sup>3</sup> *Handbuch der pathogenen Mikroorganismen*. Begründet von W. Kolle und A. v. Wassermann. Dritte, erweiterte Auflage. Jena: G. Fischer; Berlin und Wien: Urban und Schwarzenberg. 1927.

contains articles on meningococcal infections by K. W. Jötten, on gonococcal infections by J. Koch and A. Cohn, and on immunity in gonococcal infections by C. Bruck. Part 7 of volume v contains articles on infection by trichobacteria by O. Huntewüller, on the actinomycetes by R. Lieske, on actinomycosis by M. Schlegel, on Madura foot disease by A. Plehm, and on the dermatophytes (or ringworm fungi) by H. C. Plant and O. Grütz. Part 14 of volume v contains an article on the yeasts by A. Buschke and A. Joseph, one on sporotrichosis by A. Buschke and E. Langer, and another on diphtheria by H. A. Gins. Part 4 of volume vi contains articles on glanders by E. Lührs, and on *B. pyocyaneus* by A. Lode. Part 13 of volume vii contains a general account of the spirochaetes by G. Sobernheim and W. Loewenthal; various articles on syphilis by G. Sobernheim, C. Bruck, R. Prigge, and L. Laubenheimer, and a concluding one on framboesia by G. Baermann. Part 9 of volume viii contains articles on the piroplasmoses by C. Schilling and K. F. Meyer, on immunity in protozoal infections by C. Schilling, on the morphology and classification of amoebae by W. v. Schuckmann, and on amoebic dysentery by W. Fischer. Part 10 of volume ix contains articles on pleuro-pneumonia in cattle by H. Dahmen and M. Ziegler, on rinderpest by B. Albrecht, on African horse sickness by G. Liechtenfeld, on infectious anaemia in horses by T. Oppermann and M. Ziegler, on Bornasche Krankheit (meningitis) in horses by W. Zwick and O. Seifried, on distemper in dogs by H. Schroeder, and on fowl-pest by F. Gerlach.

#### HEALTH ADMINISTRATION.

WHILE public health, alike in theory and practice, is based on the application of medical knowledge, the members of local authorities responsible for its administration usually consist for the most part of persons without special medical training. The general public, which provides the *corpus vile* for the public health administrator, and which has most to gain or most to lose by the skill or incompetence of his efforts, is also a lay body, observant enough of results achieved, but unfit fully to appreciate the methods by which they were arrived at. Health propaganda in this country is at present moving along the lines of furnishing the information on these matters of health which the laity seems to require. The recent issue by the Scottish Board of Health, at a modest price, of pamphlets on the Schick and Dick tests, on encephalitis lethargica, and on ultra-violet ray therapy, intended for the perusal of members of local authorities, is an effort towards the health education of lay representatives, while the health weeks and other special enterprises, which are cordially aided by the press, bring under the notice of the general lay public the health problems of the day, and suggest ways in which the public may co-operate for their solution.

A volume<sup>1</sup> by Dr. CARL E. MCCOMBS, recently issued from the National Institute of Public Administration and New York Bureau of Municipal Research, aims to provide the layman in America with the same kind of insight into public health administration as has been referred to above. The book falls naturally into three parts. In the first, the health functions of a municipality are discussed. It is pointed out that in America the degree of responsibility for the health of their citizens conferred on municipal bodies varies greatly in the different States. The view is expressed that all health and welfare services in administrative areas should be co-ordinated under one management. In the second part, referring to vital statistics, the author points out the difficulties which arise from the differing laws as to the registration of births and deaths in different States. The health officer, he thinks, should be the registrar. The third part is concerned with the treatment of the sick. Dr. McCombs does not favour a free public medical service, but he thinks that the municipality, while undertaking the care of infectious cases and of the sick poor, ought at the same time to provide general hospital accommodation at reduced rates for those unable to pay high charges. The educa-

tional value to the general public of a good hospital and nursing service is emphasized. The working of a public health laboratory is described in some detail. The book as a whole conveys an impression of the systems of health administration now current in the American Union. The instances quoted are often illuminating. Urging the importance of registration, the author cites the case of an American citizen during the general war who, possessing no documentary evidence of his birth in the United States of America, was compelled to serve in a European army.

#### EMULSIONS.

DR. WILLIAM CLAYTON's book *The Theory of Emulsions and their Technical Treatment*<sup>2</sup> first appeared in 1923, and the fact that a second edition has already been required is an indication that this work, which deals with highly specialized problems, has earned general approval. Colloidal chemistry has undergone a rapid development in recent years, but the author has brought the present volume thoroughly up to date, although this has involved re-writing a large proportion of the book. The laws governing the production of emulsions are of peculiar complexity and obscurity. The number of important technical processes which depend upon these laws is, however, remarkably large. A few of such processes are the manufacture of ice cream and margarine, the cleansing of condenser water, the separation of water from crude oil, and the recovery of ores by the flotation process. The book deals chiefly with the general theories underlying the processes of emulsification and de-emulsification, but reference is made to certain problems of particular interest to medical science. For instance, the methods used in emulsification of drugs are referred to briefly. A good deal of space is devoted to the problem of dual emulsions, and this portion will be found of great interest by those who are concerned with the fundamental properties of protoplasm. There is a considerable amount of evidence that indicates that the surface of the living cell is composed of a reversible emulsion of lipid and protoplasm. The author discusses fully the influence of ions on oil-water emulsions, and this, in particular, is a problem of great biological interest.

#### THE NATURE OF MIND.

DR. PAUL BOUSFIELD and Mr. W. R. BOUSFIELD have written a volume on *The Mind and its Mechanism*<sup>3</sup> in which they endeavour to explain the phenomena of mental life by postulating the existence of a real psychic structure or "psychoplasm" which, like protoplasm, is an essential part of each living cell. As to the possible basis of this psychoplasm the authors take the analogy of the etherial protons and electrons which constitute matter, and postulate analogous etherial units of a finer order which they term "psychons." It is suggested that just as protons and electrons are aggregated into protoplasm so may psychons be aggregated into psychio structure. Electrons and protons are both considered to belong to the physical realm, and psychonic substance is considered to be of mass so small as to be practically inappreciable.

Though this book is highly speculative the hypothesis which it is intended to elaborate is ingeniously worked out. In successive chapters the assumed existence of "psychonic substance" is utilized to explain consciousness, the "psychic organ," memory, the transformation of ideas, the energy of ideas, emotion, the unconscious mind, the "censor" of Freud, hypnosis, telepathy, and evolution. The writers strongly favour the Lamarckian theory of evolution, taking the view that habits become ingrained in the "mental structure" of the organism, and that the psychic structure of the germ plasma is thereby cumulatively affected.

We are not quite sure whether hypotheses such as those

<sup>1</sup> *The Theory of Emulsions and their Technical Treatment*. By William Clayton, D.Sc., F.I.C. Foreword by Professor F. G. Donnan, C.B.E., F.R.S., etc. Second edition. Textbooks of Chemical Research and Engineering. London: J. and A. Churchill. 1923. (Demy 8vo, pp. xi + 253; 42 figures, 15s.)

<sup>2</sup> *The Mind and its Mechanism*. By Paul Bousfield, M.R.C.S., L.R.C.P., and W. R. Bousfield, R.C., F.R.S. London: Kegan Paul, Trench, Trubner and Co., Ltd.; New York: E. P. Dutton and Co. 1927. (Demy 8vo, pp. vii + 224. 9s. net.)

<sup>3</sup> *City Health Administration*. By Carl E. McCombs, M.D. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1927. (Demy 8vo, pp. x + 524. 24s. net.)

developed in this book really add to our understanding of the phenomena of mind. Memory, "meaning," and consciousness are but manifestations of life which are no more and no less mysterious than the physiological processes of the living organism. It seems doubtful if it is either necessary or desirable to postulate, after the manner of the authors, two kinds of energy in the living organism—physical energy traceable to the sun, and psychic energy to the "psychic environment." What can be definitely said is that matter infused with life behaves otherwise than inert matter, and perhaps this difference is best summed up in Rignano's formula—"living things remember, inert matter does not remember." (See the review of *Biological Memory*, BRITISH MEDICAL JOURNAL, August 20th, 1927, p. 310.)

### NOTES ON BOOKS.

DR. GUSTAVE MONOD has published a French translation<sup>7</sup> of the second edition of Professor MAX EINHORN's book on the duodenal sound. The volume is well illustrated, and the subject matter, in Dr. Monod's lucid style, describes clearly this effective method of duodenal investigation and treatment. We published a review of the German edition of Professor Einhorn's book on August 23rd, 1924 (p. 325), and of the first American edition on November 6th, 1920 (p. 704).

True to his faith in the efficacy of oleum alii as a curative agent in cases of chronic tuberculosis, Dr. W. C. MINCHIN has issued a third edition of his monograph,<sup>8</sup> of which the two previous editions appeared in 1912 and 1915 respectively. Further experience, he tells us, has confirmed his previous views. The present edition, however, contains more than this. Puzzled, as so many other observers have been, as to the significance of the minute granules and spherical bodies so often noted in association with the tubercle bacillus, he initiated a series of observations, with expert assistance, and claims to have proved that some of these bodies are able to pass the Chamberland filter, to be stained, and to resist acids, alcohol, and oil, and to infect guinea-pigs with tuberculosis. Similar minute bodies have been studied by other observers. Dr. Minchin regards them as yeasts, and would explain their action as fermentative.

MISS MARY WALLER has written a very useful handbook of *Practical Physics for Medical Students*.<sup>9</sup> As it is intended for use in the laboratory there are no illustrations, but repeated injunctions are given to the student to draw a diagram before starting an experiment. The book is to be used in close connexion with the lecture course, therefore no textbook material is included. In her preface the author states that the book is the outcome of some years' experience of the particular problems which arise in the teaching of medical students. Their time is limited, and their knowledge of physics is not expected to be profound, but it must be adequate and accurate, and should be based on sound experimental knowledge. The book is so arranged that students who have already had a scientific training can profitably follow the complete course given, while at the same time students just beginning experimental work in physics can perform only the experiments indicated. They illustrate general measurements, hydrostatics, mechanics, miscellaneous properties of matter, heat, light, sound, magnetism, electrostatics, and current electricity. As the book is intended for medical students certain experiments which should prove peculiarly useful to them have been included—for example, spectroscopy, surface tension, viscosity, induction coil, polarization, psycho-galvanic reflex, and the use of the electricity mains. A list of useful constants and mathematical tables published by the Board of Education is appended. This little book is so lucid and concise, and so definitely supplies a want, that we may hope that Miss Waller may presently write a textbook of physics for medical students.

*Selected Papers of Karl Abraham, M.D.*,<sup>10</sup> consists of a translation of his more important psycho-analytic works, except his *Traum und Mythos*, which has already appeared in English,

and his study on Amenhotep, for which room could not be found in this volume. The author of these essays died in 1925, and Dr. ERNEST JONES has written a lengthy introductory memoir giving a summary and appraisal of his numerous contributions to psycho-analysis and a sympathetic appreciation of his character. The author was a psychiatrist, and this work includes a number of studies of the psychoses from the psycho-analytic standpoint. It is evident that he nourished the hope that the application of the psycho-analytic technique in cases of manic-depressive insanity, during the intervals between attacks, might prove to be of therapeutic value. How far such a hope will be realized time alone will show. Meanwhile, the clinical manifestations of this psychosis are suggestive of biogenetic rather than psychogenetic causation.

The thirty-eighth annual edition of *Burdett's Hospitals and Charities*<sup>11</sup> contains several new features and improvements designed to keep the book abreast of the unending philanthropic developments in the British Isles and abroad. The chapter devoted to the work of the Hospital Saturday Fund has been augmented by a table showing in detail the progress made from 1893 to 1926 inclusive. More space than hitherto is given to the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society, and comments are made on such important subjects as co-operation between voluntary hospitals and Poor Law infirmaries and the urgent problems created by the increasing number of road accidents. The new developments in the London School of Hygiene and Tropical Medicine are indicated, and prominence is rightly given also to the Liverpool School. A new subsection has been devoted to societies for providing legal aid. The names of the medical staffs of all the teaching hospitals in the provinces, Scotland, and Ireland have now been added, and much valuable information about the different tuberculosis sanatoriums has been incorporated. The section devoted to overseas hospitals has been somewhat curtailed, but the directory of British hospitals in Europe, chiefly used by tourists, and the list of nursing establishments abroad have been retained. The directory of institutions includes universities, colleges, and schools; the hospitals in the empire and foreign lands; educational and charitable funds and institutions; nursing associations throughout the world; and periodicals published in Great Britain and Ireland dealing with medicine and allied subjects. It would be difficult to praise too highly this indispensable reference book.

The League of Nations Commission on Human Trypanosomiasis, consisting of delegates from Britain, Belgium, France, Germany, and Portugal, commenced operations at Entebbe in the beginning of 1926, and has just issued an interim report (CH. 536) on its activities. The report consists of an introduction on the general programme of the Commission (by Dr. H. L. Duke, the British delegate and chairman), and a number of articles written by various individual members. These articles include accounts of the commission's epidemiological, therapeutical, laboratory, diagnostic, and zoological studies. Owing to the interim nature of the report few definite conclusions are reached, but the lines of research contemplated promise to bring results of considerable importance in the fight against sleeping sickness.

<sup>11</sup> *Burdett's Hospitals and Charities*, 1928. Founded by Sir Henry Burdett, K.C.B., K.C.V.O. Thirty-eighth year. London: F. and W. Gwyer, Ltd. (The Scientific Press). 1928. (Demy 8vo, pp. xvii + 895. 21s. net.)

### PREPARATIONS AND APPLIANCES.

#### "ALEPOL."

"ALEPOL," manufactured by Messrs. Burroughs Wellcome and Co., consists of a selected fraction of the sodium salts of the total fatty acids of hydnocarpus oil, and is recommended for subcutaneous or intramuscular injection.

When modern investigations confirmed the traditional value of chaulmoogra oil in the treatment of leprosy, the chief difficulty encountered was the discovery of a method of administration suitable for prolonged treatment. This difficulty was due to the highly irritant nature of the crude oil. Several years ago Messrs. Burroughs Wellcome prepared a mixture of esters of acids of the chaulmoogric series, which has been widely used in leper colonies. Hydnocarpus oil contains fatty acids which resemble those of chaulmoogra oil and have the same pharmacological actions. The former oil has, however, the advantage of being more easily obtainable.

"Alepol" is a selection of the lower melting point sodium salts of the fatty acids of hydnocarpus oil, and this selection obviates, to a considerable extent, the old disadvantage of vein blocking which tended to occur when these compounds were given intravenously. The makers say that the clinical trials of this preparation have proved satisfactory.

## MOTOR CAR COACHWORK FOR THE MEDICAL PROFESSION.

[FROM A CORRESPONDENT.]

So many different styles of bodies for motor cars are on the market to-day that it has become difficult for the medical practitioner to decide which will meet his special requirements. Particularly does this apply to the small-powered less expensive cars. In order to withstand the ordinary wear of a continuous daily service, year in and year out, for both the town and country practitioner, workmanship and materials are important if heavy repair bills are to be avoided. With the variable climate experienced in this country, the progress that of recent years has been made in design, and the aid of new materials together with modern methods of construction, the closed body with its mechanically adjustable windows and a light permanent top, or the cabriolet coupé with the upper structure made to open when desired, probably stands first. They are designed for all-weather protection, which an open car, even when fitted with a conventional hood and side curtains, cannot give.

With a large number of medical practitioners self-driving is the rule; hence the popularity of the coupé or complete style. A design which is preferable is that frequently spoken of as a foreshortened saloon. A body of generous dimensions, with separate adjustable seats in front and two occasional spring seats, staggered for comfortable leg room at rear, fitted parallel with the sides, into which they fold when not in use, accommodates four passengers; luggage is carried in the tail-end of the body. The car is easily entered; moreover, it is theft-proof, as the rear extension has no doors or lids to open externally. A modification of this body is the quarter light coupé. Mann Egerton and Co., Limited, of Norwich, Ipswich, and London, have for many years specialized in this particular type of body. It is known as the "all-purpose coupé cabriolet," and it makes an ideal vehicle for a doctor, either for professional or pleasure purposes. It accommodates four persons under the hood, and contains a roomy hoot for luggage and bags, readily accessible from the interior of the car, this being a great convenience for a doctor. A comfortable detachable dicky seat can be fitted in addition, so that the car will carry from two to six persons, and it can be used either as a completely open or closed car.

But the closed car of the coupé style, though useful, does not possess to a high degree the points, most essential to medical men, of silence, comfort, and roominess. To eliminate all liability to rattle, or drumming noise, as well as to prevent the chassis frame distortions and vibrations being conveyed to the interior when travelling over rough roads, the body should be practically isolated from the chassis. This may be done by some special form of suspension, as in the Daimler cars, or by bedding the bottom of the body on thick felt or rubber. These constructional features are of such importance in the production of a silent interior that the shell framework of many forms of bodies, particularly those fabric-covered, is built distinct and apart, as in the Weymann fabric flexible body. The body shell framework is developed in a series of parallelograms, the various components being held together by steel plates with intervening air spaces, so that no noise or squeaks are set up by the ends rubbing together. In other bodies the framework joints are cushioned in rubber or a similar resilient material, and the rigid wood framework separated from the seats and flooring. For the medical man after a laborious day a restful, quiet interior is of importance, and it is suggested that good service, embodying all the desirable qualities of silence, comfortable seating, and durability, will be found in bodies built with a rigid framework panelled in aluminium for the lower part, and with flexible covered upper structure above the waist rail. The question of cushion comfort depends upon proportional measurements as to the height of the compressed cushion from floor, as well as the slope from the horizontal line, in combination with

the slope of the back, squabbed deeply and upholstered at points that will give support to the back and shoulders. Well built cushions are constructed on a double-deck principle, with two tiers of coiled springs of different gauges within a light wire frame, above which is a squab made of curled horse-hair. The cushions are ventilated to allow of the escape of air when compressed. As a substitute for springs pneumatic air-filled tubes, which can be inflated to the desired resiliency, are finding considerable favour. Sorbo rubber sponge is found to give a particularly soft and easy cushioning on the roughest of macadam roads.

The roomy quarter light coupé will provide good service to the medical man, when built on modern lines with all-metal front structure supporting a windscreen of a single deflector panel. On a standard chassis from 15 to 20-h.p. the body space will permit of a roomy body with extra seats, as previously mentioned, and an enclosure in the tail-end, with hinged doors, forming a receptacle for carrying instruments, cylinders of oxygen, and bags for miscellaneous drugs, etc.

The trend of design in all motor cars is for a lower overall height from ground, high waist, and shallow windows; but as long as the road clearance and standard head room are provided this will not affect the interior roominess for the extra seats and a suitable convenience for carrying the necessary surgical and other appliances all forward of the rear axle. In the interior of the closed car considerable improvement has been effected in the many appendages and necessary furniture, such as mechanical lifts for the frameless glass windows, moving in felt and rubber lined channels.

The prospective owner should satisfy himself that the seating arrangement and head and leg room meet with his approval; he should be equally satisfied that in the construction every contrivance has been introduced for abolishing shocks and nullifying rattles. Soft roofs, composed of leather and built up with an underlay of waterproofing material, are conducive to a silent interior, and are found most durable. In the construction of the doors spring-loaded hinges

Mann Egerton Coupé Cabriolet on 16-h.p. six-cylinder Sunbeam Chassis.

should be used, so as to take up the wear and avoid rattle from this source; while on the lock side silencers and dovetails should be fixed, of a three-way action, as a supplementary means to securing perfect rigidity. In the assembly of the wings and stepboard brackets no two metals should come in contact; they should be separated by a thin strip of leather; and in case of rear wings, at the arches, rubber tubing slit open at one edge, between the undersides of body and wing before finally fixing. The bonnet should preferably lock down on a base of rubber. Windcreens should also have their fixed portion, if any, bedded in rubber; but the present tendency, with the advent of wind-screen wipers, is towards the single-piece screen, adjustable from the top. Floor boards should be as large as possible, clamped to avoid shrinkage and warping, and lipped to prevent hot air and fumes from entering the body. Mats of a material that does not conduct heat should cover the floor boards, while a thin, non-conducting material between the cushions and seat boards also prevents the entrance of hot air and fumes. The method of attaching the interior upholstery, which is permanently fixed, influences to some extent a silent interior. In the best finished cars it is usual to have a rich West of England cloth, preferably of the plain stretched pattern, of a colour to harmonize with the painting.

As regards external finish the improvement in cellulose enamel or lacquer of a bright, lustrous finish appeals strongly to many owners, both from the point of view of durability and of economy of labour in cleaning the car. Small scratches and blemishes are easily removed without the expense of a revarnishing, as in coach painted brush work.

For economy in running cost, general up-keep, and garage space, the coupé with a car of medium horse power, and designed to dispense entirely with a dicky seat, thus offering the additional advantage of the back being left free to carry any surgical appliance, is excellent for medical men.

## THE VALUES OF DEATH CERTIFICATION.

THE practice of certification of the causes of death makes a double appeal to members of the medical profession. The immediate call arises when a certificate has to be provided in an individual instance. The wider claim recognizes that from certification there issues statistical information of high scientific, social, and economic importance. Conclusions regarding the frequency of various diseases, the decline or advance of each from year to year, and the relations of age, occupation, habits, and geography to pathological processes, are, with seeming justification, based upon the Registrar-General's returns; and, of course, towards these returns each certificate of the cause of death is an individual contribution. Clearly, therefore, the aim must be to secure in each contribution a maximum of accuracy. It is allowed that there are obstacles to this ambition, and that, as a fact, the aim is not invariably attained; hence efforts, of which the new form of death certificate recently issued is an example, to cultivate and secure accuracy in increasing measure. It is understood that the whole subject just now is receiving official consideration, and some of its aspects may therefore not inappropriately be submitted to the attention of our readers.

As a general proposition it may not unfairly be said that the larger values of accurate death certification are not often pressed on the notice of the general body of the medical profession. The official figures make their usual statutory appearance, and offer opportunities for passing comment and comparison, but they have little abiding influence. No practical application seems to be attached to them, and they do not secure the attention that is excited by challenge or controversy. Is it not possible to bring them, or some of them, into the medical arena as bearing on particular points of medical doctrine or opinion? Certainly some of the conclusions urged on the basis of the official figures are in apparent conflict with teaching proposed from other sources. Where such disparity exists there is obviously opportunity for inquiry and argument and debate, and some of our medical societies would surely provide an appropriate platform. No doubt contributions on the general values of accurate death certification have their worth, but here we are thinking rather of limited topics chosen as bearing on medical teaching and on medical practice. For example, some recent figures suggest that the age distribution of cancer and the class incidence of this disease may have important relations to the prevention of cancer. If such conclusions are to be made effective the figures on which they are based must be brought to the test of debate, and not simply announced as authoritative totals carefully registered in appropriate official departments.

There is the more need for such developments as are here advocated seeing that, with or without justification, the official returns of the causes of death are received with some measure of incredulity. Their general appreciation will therefore be promoted if, in particular respects, they can be shown to be confirmed by other observations. Especially is this true if such confirmatory observations are supplied by actual *post-*

*mortem* examinations, for here we pass from the region of opinion to that of demonstration. The official figures are naturally impressive from their bulk and from the wide area from which they are collected, and no quotation of the experience of an individual practitioner or institution could be set on the same level. But *post-mortem* records, collected from all the principal hospitals of the country, would constitute a body of evidence not to be ignored; and if such evidence proved to be in harmony with the official figures on any selected issue, the appreciation of the official figures in general would certainly be increased. The claim, therefore, is that the value of the recorded results of death certification will receive wider recognition when these results are presented as topics for discussion and debate, and when they can be shown to be in harmony with information gathered from other sources.

Incidentally, we note that in the new form of death certificate the performance or non-performance of a necropsy must definitely be recorded. Time will therefore bring a body of verified knowledge, valuable in itself, and valuable also as a check upon other certificates having a somewhat less confident quality. The most sure of all bases for death certification is obviously *post-mortem* examination, and possibly the day may come when the public will recognize the value of such examinations, not only to medical science, but also to the equipment and efficiency of the individual practitioner as an adviser of individual patients. Certainly the more numerous the death certificates resting on this basis the more widespread will be the confidence given to the official returns.

In the meantime, and probably for many years, the great majority of deaths will not be certified on the fact of *post-mortem* examination, and the returns must rest on the care and judgement with which certifying practitioners carry out the duty prescribed for them. The question therefore arises whether the educational efforts directed to this end are adequate. Presumably in the medical curriculum the lecturer on public health or forensic medicine, in drawing the students' attention to the legal responsibilities of medical practice, must speak of medical certificates in general, and of the certificates of the cause of death in particular. The occasion might well be taken to emphasize the wide and important relations of death certification, for here is an inspiring motive for the cultivation of accuracy in the individual certificate. Practical teaching in the actual writing of the certificate has its opportunities in every hospital ward; were such opportunities utilized the young practitioner would surely cease to be embarrassed when he is first called upon to sign a certificate of the cause of death. A few doctrinal explanations and actual experiences would promptly reduce the responsibility to its very simple proportions. Possibly some practitioners fail in full attention to the notes and suggestions printed with the books of blank certificates. These are most helpful, and they show a very modest set of demands. What is desired is not a severely critical exercise, but a broad statement of the disease which has produced the patient's death. Thus, to take a single example, the Registrar-General is concerned to know how many persons die from phthisis pulmonalis, but is relatively little interested in knowing how many of these die from exhaustion and how many from hæmoptysis. In many cases a single term fully meets the demand, though admittedly there are experiences which may not be so easily satisfied.

That more accuracy should be attempted in death certification is a proposition to which all will assent.

This end, we suggest, will be promoted by bringing some of the official statistics into contact with other sources of medical knowledge, by emphasizing the wide bearing of death certification, and by introducing the medical student both to the certificate itself and to the sanctions on which it rests.

### A NEW WAY IN PUBLIC HEALTH.

WHEN the Local Government Act of 1888 laid down that no person should be appointed the medical officer of health of any county or district having a population of 50,000 or over unless he held a diploma in sanitary science, it made a provision which was greatly in the interest of the beneficiary areas. In drawing the line of demarcation the Legislature may be presumed to have taken the view that, while the health affairs of populations of 50,000 and over were of sufficient weight to demand the services of a "specialist" trained in the field of health, those of populations of lower dimensions might safely be entrusted to an "ordinary" medical man, qualified in general to practise medicine, surgery, and midwifery, or, in terms of the Act, where the Local Government Board saw fit, to a man without any medical qualifications at all. In the present day, with its wider outlook and its Sanitary Officers Order, 1922, such a view may seem circumscribed, yet at that period it was not unreasonable. The hygiene of the time was largely environmental; questions of water supply, drainage, and sewage disposal awaited settlement, and the problems which arose, while acute in the cities, were much less urgent in smaller areas, with the people more dispersed or in the open country.

The Act of 1888 notwithstanding, the Local Government Board, as long ago as 1872, had recognized for areas of all dimensions, great and small alike, the importance of having a specialist officer in the sense of one who devotes his whole time to public health work, and towards this end had urged upon districts that they should combine. On this ground, and doubtless in some cases on grounds of economy also, a number of combinations were made, adjacent areas joining together to appoint one common medical officer of health. For a time these combinations appeared to be adequate; they covered the environmental field. Then new issues began to arise as the scope of hygiene widened. Since 1907 administration has taken in school medical work, maternity and child welfare, tuberculosis, venereal disease, and other subjects, not all supervised by the public health authority, yet all germane to public health. For these new services the public health combinations failed; in some respects they were too narrow, in others they overlapped; a new way had to be found.

The new way, which goes far to solve the problem, is to co-ordinate the services of an area in such a manner that the medical officer of health of each district is also an officer of the county council. It is the subject of a report by Dr. James Pearce, lately issued by the Ministry of Health,<sup>1</sup> which deals more particularly with the counties of Essex, Hampshire, Gloucester, and West Sussex, but at the same time treats of the principles involved in a lucid and interesting manner. Each district has its own medical officer of health; and so remains autonomous; but its medical officer is also assistant school medical officer of the county in his district, or assistant school

medical officer and assistant tuberculosis officer, or else he holds the two last-named posts together with that of assistant maternity and child welfare officer. Complete co-ordination is thus effected in the person of the district medical officer of health, who holds all the reins of district administration, working either in concert with, or under the supervision of, the central department of the county. The fact that he works under dual control has apparently created no difficulty. The opinion of forty-seven authorities in the counties concerned, as expressed to Dr. Pearce, was in general favourable to the new scheme. The most emphatic approval was that of the authorities whose sanitary standards were highest. Two only, and these not the most zealous, evidently thought their new officer too energetic.

Apart from the direct administrative advantages for the control of infectious disease, the supervision of tuberculosis, the amelioration of housing conditions, and kindred matters, Dr. Pearce brings out, as a point of importance to the public health service and the medical profession, the wider range and interest to medical officers of the co-ordinated scheme, which relieves the monotony of the routine examinations incidental to school and tuberculosis work, and which, if extended in the future, will offer many assistant officers an escape from the backwaters of the health service into its main current.

It is customary to decry the local government system of England on account of sundry defects. This report shows that, given goodwill and enterprise, results can be obtained under existing conditions which, for practical purposes, could scarcely be bettered by a complete reorganization.

### ABSORPTION FROM MUCOUS SURFACES.

THE question of absorption of materials from mucous surfaces is one of considerable practical interest both to the clinician and to the toxicologist, but although a great deal of work has been done by physiologists on questions relating to cell permeability in general, the reports of direct observations of the penetration of substances into mucous membranes are comparatively few. General considerations of permeability, and experiments on the passage of substances from the cerebro-spinal fluid into the blood (Dixon, Dolmo Lecture, 1925), suggest that one of the determining factors may be the size of the molecule of the substance employed. Thus crystalloids in general pass freely from the cerebro-spinal fluid to the blood; insulin, Witte's peptone, and secretin do not; and there are fairly good grounds for supposing that the molecules of insulin and secretin are large ones, while we know that the Witte peptone consists for the most part of polypeptides. The difference, however, between absorption from the cerebro-spinal fluid and from the stratified epithelium, of which many of the mucous surfaces of the body are composed, is great. Direct experiments by Knaus<sup>1</sup> showed that pituitrin was absorbed from the mouth and the rectum, but from no other part of the alimentary tract. He failed to confirm the results of Wolfe,<sup>2</sup> Hamill,<sup>3</sup> and Donaldson,<sup>4</sup> who concluded that pituitrin could satisfactorily be absorbed from the alimentary canal. In 1917 Macht reported some very interesting experiments dealing with absorption of drugs from the vagina. The materials tested consisted of certain inorganic salts, alkaloids, and antiseptics, and were all crystalloids. He found that they were, without exception, rapidly absorbed, and produced

<sup>1</sup> The Co-ordination of the Public Health Services in the Counties of Essex, Hampshire, Gloucester, and West Sussex. By James Pearce, C.B.E., M.D., on Public Health and Medical Subjects, Office. 1928. 6d. net.

<sup>1</sup> BRITISH MEDICAL JOURNAL, February 6th, 1926.  
<sup>2</sup> Brit. Min. Week., 1921, 5, p. 101.  
<sup>3</sup> Proc. Roy. Soc. Med., 17, 1921.  
<sup>4</sup> Ibid., 19, 1921.

their typical physiological and toxic effects to a marked degree. Ho quoted, in addition, many cases from the literature in which serious—sometimes fatal—effects followed the introduction into the vagina of substances for therapeutic or, in a few cases, criminal purposes. At the moment considerable interest attaches to the administration of insulin by routes other than the subcutaneous, which, if used over long periods of time, becomes increasingly unpleasant to the subject. Notwithstanding reports from some German physicians,<sup>5</sup> the weight of evidence seems to point to the fact that insulin is not absorbed from the alimentary tract. Up to the present the results obtained with synthalin and allied substances are not sufficiently encouraging to warrant their general adoption, and the question arises whether insulin could usefully be given by any other route. In 1923 Fisher and Noble<sup>6</sup> reported that insulin was absorbed when injected into the vagina. Recently Robinson<sup>7</sup> has reported experiments which serve to confirm the work of Macht, quoted above, and which, in addition, confirm that of Fisher and Noble on the absorption of insulin. Robinson found that adrenaline, secretin, and Witte's peptone were not absorbed; with pituitary extract the oxytocic, but not the pressor, effect was obtained. This last point, taken in conjunction with the similar result obtained by Knaus on the absorption of pituitrin from the mouth, may perhaps be considered as tending to support the idea that in pituitrin we have to deal, not with one substance, but with two. Robinson, unlike Macht, took special precautions to avoid absorption from the cervix uteri.

#### DEFECTIVE STRUCTURE OF TEETH.

From the Department of Pharmacology of the University of Sheffield comes an essay by Mrs. Mellanby (reprinted from the *British Dental Journal* of July 1st, 1927) containing a summary of the results of her investigations during the last four years into the prevalence of hypoplasia in the teeth of English children of to-day. After prolonged research, in the course of which 1,036 deciduous teeth and 266 permanent teeth were submitted to microscopic examination, she confronts us with figures showing a prevalence of hypoplasia to a degree hitherto quite unexpected. She distinguishes three degrees of hypoplasia. Of temporary incisors 49 per cent. were normal, 14 per cent. hypoplastic or severely hypoplastic. Of temporary canines 8 per cent. were normal, 54 per cent. hypoplastic or severely hypoplastic. Of temporary first molars 7 per cent. were normal, 73 per cent. hypoplastic or severely hypoplastic. Of temporary second molars 1 per cent. were normal, 92 per cent. hypoplastic or severely hypoplastic. The remainder showed slight hypoplasia. Of the permanent teeth (the wisdom tooth is the only one not examined) none were normal, and only one tooth, the second premolar (62.5 per cent.), showed an incidence of hypoplasia or severe hypoplasia of under 90 per cent., the second molar reaching 100 per cent. To emphasize the tangible nature of the defect these figures point to, Mrs. Mellanby gives tables showing that by macroscopic observation in the mouth or in the hand (by means of a somewhat blunt probe to detect roughness, and by visual estimate of hypoplastic enamel) practically identical figures were obtained. Another table showing that the teeth from dental clinics are decidedly worse than those from private sources, and the observation that the temporary incisors are the best formed teeth, suggest that malnutrition is the factor responsible for the wide spread of dental hypoplasia—a theory which is entirely at one with the current view of its origin. Mrs. Mellanby believes that the incidence and severity of hypo-

plasia have a definite relation to the incidence and severity of dental caries. She is careful to define what she means by hypoplasia, and it is here that a possibility of error presents itself. It is well known that the dentine of the teeth of ectopoda, for instance, shows large numbers of interglobular spaces—are we to expect perfection in man only? Again, she says: "It is interesting to note that the interglobular spaces, especially in the incisors and first molars, are usually situated fairly near the amelodentinal junction, in contrast with the deciduous incisors, where any defects are usually found towards the pulp." The granular layer of Tomes, situated close to the amelodentinal junction, has always been considered a normal structure, and it may be asked whether this is the layer to which Mrs. Mellanby refers. As regards the relationship of caries to hypoplasia, Mrs. Mellanby is rather unfortunate in Fig. 14, in which the carious area is the only part free of interglobular spaces. The figure seems to suggest that environment is the more important factor in the production of caries. Importance is attached by the author to variations in the rate of calcification, and it is suggested that the second temporary molars, for example, are more hypoplastic because of more rapid calcification. We may be allowed to ask for the proof of this suggestion. We may ask, too, for proof of the statement that "no doubt . . . increased maternal dental decay is due to the sacrifice of the mother to the growing organism of substances essential for her own welfare." But these are side issues. The main point stands. By patient and careful investigation Mrs. Mellanby has demonstrated the existence of dental hypoplasia among English children to an extent hitherto undreamed of. With a generous allowance for Nature's wasteful methods there must still be a large preventable residue—and sound teeth will assuredly be the better adapted to resist the inroads of decay. We may go a step further. Children with well formed teeth are likely to be of a healthy constitution—"dens sana in corpore sano"—and Mrs. Mellanby may have found a touchstone for an A1 population. She acknowledges her indebtedness to the Medical Research Council and the Dental Board of the United Kingdom for the costs of the investigations. We think the whole medical profession will cordially agree.

#### IRAQ COLLEGE OF MEDICINE.

THE conclusion of a new treaty of alliance between Great Britain and Iraq (writes a correspondent), and the prospect of the early admission of Iraq to the League of Nations, has brought into prominence the political and economic progress of "The Land of Two Rivers" since the accession of King Faisal. In educational matters, too, great strides have been made, and the infant Al-Al-Bait University of Baghdad already possesses Faculties of Religion, Agriculture, and Medicine. Of these the Faculty of Medicine is the most recently instituted. The doors of the Iraq College of Medicine were first opened in October last, when, following matriculation, twenty selected students began their course of studies. The University confers a single medical degree—M.D. A high standard of education is being required of candidates, and the curriculum, covering five years, is based on that prescribed for the M.B., Ch.B. of Edinburgh. The dean and the professors are all British graduates of British universities, and the teaching staff of each department includes an Iraqi. The students already admitted include Mohammedans, Christians, and Jews. Systematic lectures are delivered in English, but practical and tutorial instruction is permitted in both English and Arabic. Iraq is very poorly provided with doctors in all but the three largest towns, and the primary purpose of the College is to train suitable candidates for Government service throughout the country. With diseases such as

<sup>5</sup> *Lancet*, January 21st, 1928.

<sup>6</sup> *Amer. Journ. Physiol.* lxxvii, p. 65.

<sup>7</sup> *Journ. Obstet. and Gynaecol.*, 1925, xxxii, 1, and *Journ. Pharm. and Exper. Therap.*, xxxii, 81.

ankylostomiasis and bilharziasis rampant among the fellahoon, the necessity of this provision is very real. Students receive their instruction free on condition that they contract to serve the Government for a period of four years following graduation; while so serving, however, they will receive the same rate of pay as other medical officers of similar grade in the health service of Iraq. The College is well equipped, and is situated in the precincts of the Royal Hospital, Baghdad, where ample opportunities exist for clinical instruction of all kinds. There is great competition among young Iraqis for admission to the faculty, and, as the number of entrants is strictly limited, an excellent type of student is being obtained. Everything points to a successful future for the College, and it remains to be seen whether the present sons of this romantic country, in whose ancient capital, a thousand years ago, dawned the classical period of Arabian medicine, are capable of attaining the same heights of erudition and professional skill as their distinguished ancestors, among whom was Avicenna, "Prince of physicians."

#### THE BACILLUS CALMETTE-GUÉRIN (B.C.G.).

PROFESSOR CALMETTE is a prophet not without honour in his own country. When he concluded an address at the meeting of the Académie de Médecine on January 10th, the president of that body complimented him on being raised by the Government to the highest grade of the Légion d'Honneur—a small recompense for the immense services rendered, not only to France, but to the whole of humanity. Professor Calmette's address dealt with the results which have been obtained between July 1st, 1924, and December 1st, 1927, in the preventive vaccination of the newly born by B.C.G. (bacillus Calmette-Guérin). During the period under review 52,772 infants have been vaccinated; but the address was only concerned with 5,749 of these, who were stated to have been born of tuberculous mothers or to be living in tuberculous surroundings. Vaccinated infants under 1 year of age numbered 3,808; of these 118 were dead, a mortality from all causes of 3.1 per cent. The mortality at this age for non-vaccinated infants, whether in contact with tubercle or not, throughout France was stated to be 8.5 per cent.—a difference sufficiently startling if the former low figure continues to be maintained as the number of vaccinated infants increases. The mortality from causes presumed to be tuberculous among the 3,808 infants was 0.9 per cent., whereas the mortality for such causes amongst non-vaccinated infants exposed to tuberculous conditions was variously estimated at 24 to 70 or even 80 per cent. Only in Denmark, says Professor Calmette, has the mortality of non-vaccinated contact cases under 1 year of age been reduced to 7.7 per cent. Amongst 1,941 vaccinated contact children between the ages of 1 and 3½ years there have been 21 deaths, of which 4 were from diseases presumed to be tuberculous. The mortality of 1.2 per cent. from all causes compares with a mortality of 1.6 among non-vaccinated children with or without tuberculous contact. The mortality from tuberculous causes is 0.2 per cent., as compared with 0.14 for the non-vaccinated population of the same age. Professor Calmette believes that the immunity conferred by B.C.G. lasts longer than was at first thought, and is perhaps reinforced by virulent infections which are inoffensive for a vaccinated child. He regards this hypothesis as plausible, though not irrefutable. It is possible that the immunity continues for not less than five years, and so tides the child over the period in which it is exposed to severe infection. The fact that the bacillus-vaccines can remain so long in the human body without producing any other effect than resistance to virulent infection removes, adds Professor Calmette, any possible anxiety as to danger resulting from the vaccine. It appears that with an increase in the

number of the vaccinated a good case can still be made for pre-immunization of the newly born by B.C.G., at all events for those in tuberculous surroundings, and there is no evidence of harm having resulted from the process. But we are still doubtful whether Professor Calmette's results have been sufficiently submitted to expert statistical investigation. We hope that as the number of the vaccinated increases the cases will be kept in sight, with the object, ultimately, of a strict statistical review. It is interesting to note that on January 3rd Dr. Gram reported to the Académie de Médecine observations made at Oslo by the Norwegian doctors Heimbeck and Scheel on the use of B.C.G. in persons who gave a negative result to the von Pirquet reaction. Such persons were presumed never to have suffered from tuberculosis, and therefore to be liable to grave infection from massive doses. Vaccination with B.C.G. resulted in a positive von Pirquet reaction, but without any sign of disease. The observers believed that B.C.G. was entirely harmless in such cases, and might be preventive against tubercle. Professor Calmette considered that even if tuberculosis was present a subcutaneous or intramuscular injection of B.C.G. led to nothing more serious than a localized cold abscess.

#### THE VENEREAL DISEASE PROBLEM IN INDIA.

THE British Social Hygiene Council recently sent a delegation to India, consisting of Dr. David Lees and Mrs. Neville-Rolfe, and in the twelfth annual report issued by the council some account is given of the results of the tour. Seven large towns were visited, and social hygiene councils, affiliated to the British Social Hygiene Council, were established in each place. The delegation found evidence in the Provinces and States of a high incidence of syphilis and gonorrhoea, and it is reported that social conditions and customs are such that the diseases are disseminated among the adolescent as well as the adult population. Many recommendations have been made, and forwarded to the Governments concerned, dealing with the medical, social, and educational aspects of the problem. From the medical point of view it is emphasized that there is need for more co-ordination of effort, with increased hospital accommodation and a free supply of pharmaceutical material. It is suggested that there should be appointed for each Province or State a specialist in venereal disease who should be a member of the surgical teaching team in the university. From the social and educational standpoint the importance of biological training is stressed, and as an emergency measure it is proposed that two prominent university professors in biology and psychology should visit the universities and educational departments in the immediate future. The social recommendations are far-reaching; they include, among other points, an extensive campaign of public enlightenment, the eventual provision of skilled medical treatment for all persons needing it, the abolition of commercialized prostitution, and an extension of the cinema censorship. The central Government has been asked to co-operate in three ways: (a) by providing in the principal seaports the cost of medical facilities for the diagnosis and treatment of venereal disease and ground for the erection of institutes affording recreational facilities for the members of the mercantile marine; (b) by co-operating with the provincial Governments and the universities in the scheme for providing two university professors to initiate additional teaching on biology and social hygiene; and (c) by taking responsibility, through the British Social Hygiene Council, for the Indianization of dramatic films for propaganda purposes. In this connexion it should be noted that the Government of India is considering the appointment of a commission of inquiry into the present film situation, and the delegation urges that the cinema censorship should be extended and that films unsuitable for

India should be banned. The council undertakes annually a vast amount of work, as a glance at the present report will show, but it is to be especially commended for the way in which its delegation has tackled a vast problem, and the working of the schemes recommended, should they be adopted, will be watched with interest.

#### AFTERMATH OF THE MISSISSIPPI FLOOD.

SURGEON-GENERAL H. S. CUMMING, of the United States Public Health Service, has submitted to Congress a report dealing with the measures taken to protect the public health after the Mississippi flood. It is thought that the economic losses and human suffering in the flood area have exceeded those in any previous disaster in the country. Emergency aid was received from the Federal, State, and local health authorities, as well as from voluntary agencies, including the American Red Cross, and an officer of the Public Health Service was stationed at the national disaster relief headquarters of the American Red Cross at Memphis, Tennessee, to act as liaison officer and to secure the necessary assistance required. Such urgently needed therapeutic agencies as small-pox and antityphoid vaccines and antitetanic serum were supplied in large quantities. Within ten days from the beginning of the emergency fourteen trained officers of the Public Health Service, familiar with the localities, were actively engaged, and the response to the demand for other trained help was so generous as to meet the chief needs of the flood area within a very short time. With the recession of the flood a joint conference of the authorities concerned was held, and a plan was devised for the establishment of county health units throughout the affected area, so as to avert the danger of epidemics of various kinds. It was observed that the counties with whole-time efficient health services met all emergencies promptly and effectually. Surgeon-General Cumming added that for a long time the people in the flooded areas would be exposed to adverse health and economic conditions, especially owing to the damage to the water supply and waste disposal systems and the curtailment of food supplies. Pellagra had increased in certain neighbourhoods, owing to the partial failure of crops as well as to the flood.

#### ESTIMATION OF HEPATIC EFFICIENCY.

The complexity of the structure and blood supply of the liver is evidently correlated with multiple function, but the part taken by this organ in the digestive, glycogenic, secretory, and endocrine activities of the body is not yet fully understood. Attempts to estimate hepatic efficiency must, therefore, be beset with difficulty, and it is not surprising that various tests have been put forward and discarded from time to time. Thus, for example, Widal's haemoclastic test, advocated by some for gauging the liver function, was condemned in our columns by A. F. Bernard Shaw (1925, i, p. 914), though Maurice Shaw (*ibid.*, p. 1020) thought this conclusion a little premature. Another line of approach was suggested in 1921 by Roch and Schiff, who employed sodium salicylate to test hepatic efficiency on the ground that this salt is destroyed by a healthy liver, and therefore does not appear in the urine. As this test sometimes gave positive results when the liver was healthy its value was admittedly doubtful, but H. Thiers has since published<sup>1</sup> a modified procedure which may be worthy of consideration. He states that a normal adult can assimilate a dose of 0.04 gram of sodium salicylate, no trace of salicylic acid being found subsequently in the urine. If the liver is damaged salicylic acid appears in the urine passed during the second to the seventh hour after the ingestion of the sodium salicylate. Roch and Schiff added the urine, drop by drop, to a

1 per cent. solution of ferric chloride, but this method of estimation gave rise to error. Thiers therefore proceeds as follows. At 8 a.m. the patient is given 0.04 gram of sodium salicylate in solution, and all the urine passed between 9 a.m. and 1 p.m. is collected in one beaker in order to eliminate the possibility of retardation in renal excretion. In some cases the quantity of urine is so small that its collection has to be continued until 4 p.m. For the estimation of salicylic acid 50 or 100 c.cm. of urine is placed in a beaker of 200 c.cm. capacity graduated at intervals of 25 c.cm., and a sufficient quantity of strong hydrochloric acid is added to acidify it. Into this mixture 25 c.cm. of sulphuric ether is poured, and the fluid is shaken energetically three times. The liberated salicylic acid is almost insoluble in water, but dissolves in the ether. In ten minutes the liquid separates into three layers; the urine forms the lowest stratum, the middle layer consists of water containing a trace of emulsified ether, and the upper frothy viscid stratum consists of ether emulsified by the nucleus of the urine and containing the salicylic acid. This frothy emulsion is decanted, and sufficient alcohol (95 per cent.) is added to decompose the emulsion. The mixture is shaken gently and allowed to stand. It then separates into two layers; the upper consists of salicylic acid in ethereal solution, while the lower contains mucus and organic and inorganic substances which precipitate ferric chloride. The upper stratum is decanted; a minimal portion of ether is lost in these successive manœuvres, but this is fairly constant and produces no appreciable error. The ethereal solution is poured into a test tube containing 19 c.cm. of the following solution: *Liquor ferri perchloridi* fort. 20 drops, concentrated hydrochloric acid 1 c.cm., distilled water to 1 litre. The contents of the test tube are well shaken three times, and allowed to stand. A positive reaction is indicated by the colourless mixture assuming a violet colour; this occurs immediately when the reaction is strongly positive, and if no colour appears in ten minutes the reaction is negative. Thiers maintains that the test performed in this way is much more reliable than the ordinary addition of urine to a ferric chloride solution, because the insolubility of salicylic acid in water prevents its diffusion in the ferric chloride solution. The test can be applied quantitatively by using a colorimetric scale prepared by titration of a standard salicylic acid solution. He claims that this test is not invalidated by circulatory failure due to cardiac or renal disease; the majority of his patients giving strongly positive reactions had more or less damaged kidneys. It should not be employed, however, during a period of profuse diuresis, as the reaction may then be negative or feebly positive. Negative reactions occurred in all Thiers's cases in which the liver appeared to be normal. The presence of urobilin interferes slightly with the colour estimation, but Thiers overcame this difficulty by practice. He thinks that this test, though empirical, has a definite clinical value, and may be used advantageously until a more systematic examination of the hepatic function is made possible by further knowledge of its physiology and pathology. Epstein, Delprat, and Kerr, who have for some time advocated the intravenous injection of rose bengal for the estimation of liver activity, have reviewed the results of investigating over 500 patients by this means.<sup>2</sup> They found that this dye, of which only a trace remains in the blood plasma of normal persons after sixteen minutes, is not eliminated for a considerable time in obstructive jaundice, catarrhal jaundice, or arsenphenamine icterus. The test therefore appears to be a valuable aid in detecting these conditions and in following their clinical course. The nephritic toxæmias of pregnancy do not delay the disappearance of this dye from the blood stream, but acute hepatic infections were shown by its use to cause marked impairment of the liver function.

## HOSPITALS AND ROAD ACCIDENTS.

In a note on page 192 of our last issue we referred once more to the heavy cost of hospital treatment for motor casualties, and mentioned the letter on this subject by Sir Duncan Kerly printed in the *Times* of January 30th. The same newspaper published on February 4th a letter by Sir Arthur Stanley stating that the British Hospitals Association and the Royal Automobile Club had the matter under consideration, and on February 7th the Earl of Donoughmore, as chairman of the management committee of King Edward's Hospital Fund for London, wrote suggesting that the fairest and most effective solution of the problem would probably be found to lie in insurance, with specific provision in motor policies for agreed payments to hospitals in respect of accident cases, and that a comparatively small extra premium might be expected to meet a reasonable scale of hospital payment. Lord Donoughmore added that the position was felt to be so serious that the King's Fund had decided to take the responsibility of inviting representatives of the hospitals, the insurance companies, and the leading motorists' organizations to an early conference on the subject. This we regard as an important step in the right direction, and we share his hope that combined effort on the part of all concerned will soon yield an equitable solution.

## PATHOLOGICAL MUSEUM AT THE CARDIFF MEETING.

The committee appointed to organize the Pathological Museum in connexion with the Annual Meeting of the British Medical Association at Cardiff next July proposes to arrange the material under the following heads: (1) Exhibits bearing on discussions and papers in the various Sections. (2) Specimens and illustrations relating to any recent research work. (3) Instruments concerned in clinical diagnosis and pathological investigation. (4) Individual specimens of special interest or a series illustrating some special subject. (5) Exhibits of general interest. The committee appeals for the co-operation of the profession in making the museum a success. It will be easy of access, being situated in the same building in which the Sections will meet; it is hoped to make arrangements for exhibitors to demonstrate their specimens. Every care will be taken of the exhibits, and the contents of the museum will be insured. The honorary secretaries (Dr. J. B. Duguid and Dr. J. Mills, Department of Pathology and Bacteriology, Welsh National School of Medicine, The Parade, Cardiff) ask intending exhibitors to notify them as soon as possible.

## A SOUTH AFRICAN FIELD HOSPITAL.

To many people there is fascination in recalling, or having recalled to them, the details of some historical event which occurred within their memory. An example of these echoes of the past is the *Diary of a Field Hospital during the South African War*, by Lieut.-Colonel G. H. Younge, R.A.M.C.(ret.).<sup>1</sup> Spion Kop, the Tugela, Colenso, Long Tom, Hart's Hill: what memories these names awaken! The author was in charge of the field hospital detailed for duty with the Irish Brigade, and so took part in the operations which culminated in the relief of Ladysmith. Of particular interest is his comparison between active warfare in 1900 and that of only fifteen years later. For the transport of his equipment bullock carts were alone available. These weighed about two tons, were drawn by teams of sixteen oxen, and carried a load of at least five tons. By how many months would the campaign have been shortened had the modern mechanical tractor been available! Colonel Younge records the fact that in January, 1900, a steady increase in the severity of rifle-bullet wounds was noted; the wounds of entrance had become large, contused, and jagged, and those of exit large, funnel-shaped, and

lacerated. The inference was that expanding bullets were being used. A curious fact is the great predominance of wounds of the lower extremities. The author recalls for us some interesting details of Ladysmith on its relief. The General Hospital, situated on nontrial ground, contained some 800 wrecks of humanity; a forest of white headstones marked the graves of 1,600 men who had been killed or had died of disease during the siege; and he notes that most of the survivors, on return to full diet, developed jaundice. Enteric fever was first encountered by him after the relief of Ladysmith, and was traced to the drinking of water from pools during the protracted battle of Pieter's Hill, when our men occupied old Boer trenches at Colenso. From March 9th, 1899, to July 8th, 1901, this field hospital alone treated 595 cases with 65 deaths, a mortality of 10.9 per cent. The author, however, considers that some of the cases returned as simple continued fever (572 cases) or as not yet diagnosed (413 cases) were in reality mild or modified cases of enteric.

## JACQUES LOEB.

At the Marine Biological Laboratory, Woods Hole, Massachusetts, a memorial bronze tablet recording his achievements under the headings "Brain physiology; Tropisms; Regeneration; Antagonistic salt action; Duration of life; Colloidal behavior" was unveiled last summer to Jacques Loeb (1859-1924). Among the "exercises" on that occasion was an appreciation of his life's work by Dr. Simon Flexner<sup>1</sup> of the Rockefeller Institute for Medical Research, which Loeb joined in 1910 after being a professor at the University of California. His family, which left Portugal to avoid the Inquisition, settled in Amsterdam and later in Alsace; he was educated at the Universities of Berlin, Strasbourg, and Würzburg, and while assistant to Fick at the last named university he came under the influence of the botanist Sachs, who turned his talents into the broad channel of general physiology. Loeb recognized that the tropisms described by Sachs in connexion with plants were applicable to animals, and was led to make ingenious experiments on animal tropisms and heteromorphosis. He was thus launched on his life's work of reducing the so-called manifestations of life to the status of physico-chemical reactions. These observations were extended to psychology, so that he applied his deductions to the explanation of certain phenomena of animal behaviour. Loeb was, Dr. Flexner said, an intensive individual investigator, and though his immediate pupils were not numerous, his wider influence reached even the educated lay public. He organized the Division of General Physiology at the Rockefeller Institute, the first department of the kind in the United States, and in 1918 founded and edited the *Journal of General Physiology*.

## THE HALF-YEARLY INDEXES.

THE usual half-yearly indexes to the JOURNAL and to the SUPPLEMENT and EPITOME have been printed; they will, however, not be issued with all copies of the JOURNAL, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this desire.

THE title of Sir Holbert Waring's Hunterian Oration before the Royal College of Surgeons of England is "The progress of surgery from Hunter's day to ours." The Oration will be given in the lecture theatre of the College, Lincoln's Inn Fields, on Tuesday next, February 14th, at 4 o'clock. A banquet to celebrate the bicentenary of Hunter's birth will be held that evening in the College.

## MEDICAL RESEARCH COUNCIL.

## ANNUAL REPORT.

## I.

THE annual report of the Medical Research Council for the year 1926-27 contains in its 150 pages a very condensed summary of many investigations proceeding in various parts of the country. It covers, as usual, a very wide field, and we shall follow our customary practice in giving a brief outline of some of the work of the several sections. Such a task is rendered especially difficult on this occasion, because the past year has been notable for many reasons, including the bringing forward of problems which have emphasized the imperial aspects of the work of the Council. We referred last year to the discussions at the Imperial Conference. As a result of these, it is remarked, "steady progress has been made towards the linkage of the research organizations in Great Britain with the equivalent organizations, either in being or foreshadowed, in the Indian Empire and in the Dominions overseas." A Colonial Medical Research Committee has been appointed, and it is suggested that as a result of the new opportunities for collaboration, and now facilities for intercourse, there may come about a veritable "Imperial Research Service." The Empire Marketing Board has shown its interest by making financial grants towards research schemes aimed at the improvement of Empire trade in given directions.

## GENERAL PRINCIPLES AND PRACTICAL APPLICATIONS.

In the introduction to the report certain aspects of the work are selected to illustrate the principles which guide the Council. The necessity of standards of reference in research work is emphasized; the Council maintains the national collection of type cultures, and at the Hampstead Institute are kept all the standard preparations required by the regulations under the Therapeutic Substances Act. The introduction refers also to the eleven years' work of Sir Thomas Lewis in clinical research and experimental medicine, and describes the investigations of the past years on the physiology and disorders of the heart as "the central stream of progress made in these subjects anywhere." The national importance of the work of the Council is exemplified by the vitamin researches. The isolation of the so-called vitamin "D" by Dr. O. Rosenheim, F.R.S., and Mr. T. A. Webster at the National Institute is traced in an admirable historical summary of the discovery of the "antirachitic" vitamin and the subsequent research work on this substance, culminating in the co-operative investigation by these workers in this country, and in Germany by Professor Windaus with Dr. Hess of New York. The practical importance of this work in relation to the food supply of the nation is emphasized, since "we now have at disposal abundant and cheap supplies of vitamin D in potent and isolated form," and the search among natural products for this vitamin is no longer necessary since "we can produce it artificially by irradiation of ergosterol." Arising out of such applications of scientific knowledge to the health of the nation as a whole, the Council also calls attention to the entire field of nutritional science, which requires careful study; a special committee has been appointed to frame a comprehensive and co-ordinated programme of work.

## WORK AT HAMPSTEAD.

In the next section is summarized the principal work during the year at the National Institute for Medical Research at Hampstead and in the associated field laboratories at Mill Hill. The section of biochemistry and pharmacology has included a large range of subjects. Dr. Dudley and Dr. Thorpe have made a chemical investigation of muscle on a large scale, undertaken as an extension of work on the nature of vaso-dilator constituents of different tissues. A peculiar peptide "carnosine" has been isolated, and investigation of its hitherto unknown functions is proceeding. Professor A. N. Richards of Philadelphia has

been working with Dr. Dale on the vaso-dilator action of adrenalin. Dr. King and his colleagues have continued their syntheses of substances likely to have chemotherapeutic values. In the section of experimental pathology, bacteriology, and protistology work during the year has proceeded on two main lines. One group of studies has been concerned with the infective viruses of various human and animal diseases, and the other has been aimed at improving methods of precision in immunology. Mr. Dobell and Dr. Laidlaw have continued their work upon the *Entamoeba histolytica*, especially directing their attention to the experimental infection of monkeys, and its treatment by emetine. In the department of applied optics Mr. J. E. Barnard has directed the improvement of microscopical methods and appliances likely to assist biological work and, in particular, the investigation of filterable viruses. The study of the reactions of the body to various atmospheric conditions and to the radiations of light, particularly in the ultra-violet region of the spectrum, has been the main work of the section of applied physiology. Dr. Campbell has completed certain experiments on the acclimatization of the body to low and abnormally high oxygen pressures in the air, and Dr. Hill, with the assistance of Miss Brad, has investigated the effects of diet upon the reproductive power and liability to cancer in mice. The work of the Statistical Committee continues to be of the highest importance, and a fruitful co-operation between statistical and psychological investigators upon telegraphist's cramp has developed. The help given by this committee in the general criticism of work of other departments, statistical verification of particular points, or in the indication of possible fallacies is emphasized as being among the most important of its activities.

## EXPERIMENTAL MEDICINE.

At University College Hospital, London, Sir Thomas Lewis and his collaborators have continued the study of the physiology and pathology of cutaneous blood vessels. The director and Dr. Grant have obtained evidence that anaphylactic poisons in "fish poisoning" act on the vessels of the skin by liberating a histamine-like substance, and the symptoms of a general anaphylactic response are attributed to a similar, although more general, release. Dr. Grant has completed and published his anatomical researches upon the coronary vessels of the heart, and his main work—a systematic examination and comparison of the coronary circulation in representative vertebrate species—has been completed with the help of Dr. Regnier. At St. Thomas's Hospital, London, work by the medical unit under Professor H. Maclean has been directed to certain experimental and clinical studies of gastric physiology and pathology, and the response of gastric and duodenal ulcers to treatment by alkalis has been watched by means of x-ray examinations. At the University, field laboratories, and Royal Infirmary, Sheffield, attempts have been made by Professor Mellanby and Dr. Cowell to control the symptoms of hyperthyroidism, as in Graves's disease, by purely medical means. Professor Mellanby has also continued his well known inquiries into the anticacifying action of cereal foods.

## PROBLEMS OF CHILD LIFE.

Studies of cases of toxæmia in the later months of pregnancy have been continued on clinical and biochemical lines at the Royal Maternity Hospital, Glasgow, and a special inquiry is being made into the carbohydrate metabolism in normal and abnormal pregnant women. Miss Widdows, Miss Bond, and others have continued their work on normal human colostrum and early milk at the Royal Free Hospital, London. These have been investigated with reference to the racial type of mother, length of lactation, method of extraction of milk, and other variables. Work on the metabolism of infants has been carried out at the Royal Hospital for Sick Children, Glasgow, under the direction of Professor Leonard Findlay. Dr. Stanley Graham and Dr. Morris have directed special attention to the acid-base balance of the blood in infancy and childhood with reference to the carbon dioxide dissociation curves in normal and abnormal conditions. The work of Dr. Leonard Parsons at Birmingham upon the

blood chemistry and bone changes in coeliac disease and in renal infantilism has shown that ultra-violet light, while beneficial in coeliac disease, may aggravate the bone changes in renal infantilism and is contraindicated. Dr. H. A. Harris at University College has studied the transverse striations of long bones which occur in non-rachitic children who have suffered from various acute illnesses. This investigator holds that the line of healing rickets of the cartilage may have a similar origin—namely, slowed growth on an inadequate diet—and that the “line-test” of healing rickets therefore presents definite fallacies.

#### HUMAN NUTRITION.

The Nutrition Committee has under consideration more comprehensive schemes for surveying, in the light of the latest knowledge, the dietetic needs of different sections of an active population and the deficiencies in national dietaries, which can be traced to remediable accidents of soil and water supply, or to remediable faults in the treatment and distribution of foods. Professor E. P. Cathcart has undertaken a study of the dietaries of the population of St. Andrews, where access to households in all grades of society has been possible, so that data of a vast economic and scientific interest has been obtained. At the Lister Institute Dr. S. S. Zilva has investigated the improvements of the methods for isolating vitamin C, and the relation of its antiscorbutic activity to the reducing substances accompanying this vitamin. With Captain J. Golding, Dr. Zilva and Miss Soames have co-operated in studies of the relative values in vitamins A and D of butter obtained from cows fed on diets supplemented by green fodder and cod-liver oil. Cows receiving the oil showed improvement in the vitamin A and D content of the butter, while green fodder improved the vitamin A content only. Miss Humo and Miss Henderson Smith, with Dr. N. S. Lucas, have found that the injection of irradiated cholesterol into the skin of rabbits and rats fed on a rickets-producing diet will prevent rickets, and that this may represent at least one of the natural means by which the body is supplied with vitamin D, since activation by light of pro-vitamin on the surface of the skin is known to take place. Professor J. C. Drummond, with his co-workers at University College, London, has been engaged on finding a suitable method for isolating vitamin A from material in a large-scale extraction of active fractions of cod-liver oil. Further work on the colour reaction for the estimation of vitamin A in relation to the disturbances produced by natural pigments in butter and milk has been proceeding, and means for avoiding this effect have been devised. Professor Drummond has also continued his work on the physiological action of vitamin B. The only clear-cut symptom directly ascribable to deficiency in this vitamin would seem to be the so-called polyneuritic or “beri-beri” condition, all other abnormalities being attributable to the loss of appetite and resulting inanition which follow the withdrawal of the vitamin. With Dr. Hassan he has shown that the physiological action of yeast is complex, due to at least two substances; the chemical nature of these two components is being further investigated. Mr. H. W. Kinnersley has obtained a highly active material, also from yeast, by Professor Peters’s charcoal adsorption method. Professor V. H. Mottram, Dr. Gladys Hartwell, and Miss Clifford have continued their work on nutritional subjects at King’s College for Women, London.

#### DENTAL DISEASE.

The lymphatic supply of the teeth in the dog and in the primate has been investigated by Dr. E. W. Fish, who finds certain fundamental differences which have a bearing on the question of dental caries, since the dog, with a free irrigation of its dental enamel, appears to escape it. Mrs. Mellanby has continued her work at the field laboratories, Sheffield, with special reference to the control over the structure of the teeth by diet and environment, ante-natal and post-natal. Miss K. C. Smyth, London, has collected measurements in selected children to show, by means of averages, the direction and normal rates of growth of the jaws as a basis for study of the abnormal.

#### DISEASES OF THE CARDIO-VASCULAR SYSTEM.

In addition to the work of Sir Thomas Lewis and his colleagues already mentioned, work on these diseases has been proceeding in other centres. Dr. J. C. Bramwell and Dr. R. Ellis at Manchester have been studying the form of the pulse wave in the central arteries in man. A portable instrument for the optical record of the rapid pressure changes in the carotid artery has been devised for use at the bedside. Dr. Ellis has followed up the results of the treatment of cases of auricular fibrillation with quinidine during the past five years, and he concludes that in the hospital class of patients at least the results are disappointing. Dr. G. Anrep at Cambridge has studied the blood supply to the heart muscle under normal and pathological conditions, and the effect of various drugs upon the coronary circulation. Changes in the coronary blood flow induced by auricular fibrillation, premature contractions, heart-block, and other conditions have been studied.

(To be continued.)

#### THE UNITED STATES ARMY MEDICAL REPORT.

THE report of the Surgeon-General of the United States Army for 1926 refers to the fiscal year ending June 30th, 1927, but the vital statistics cover the calendar year ending December 31st, 1926.

##### Medical Personnel.

In the regular force the Medical Corps comprises 931, Dental Corps 158, Veterinary Corps 126, and Medical Administrative Corps 72. There are 52 vacancies in the Medical Corps, and the Surgeon-General emphasizes, as in previous years, the numerical inadequacy of the medical personnel and the difficulty in supplying requirements. The proposed increase in the Air Corps makes the position more acute than ever. The Army Nurse Corps contains 493 regulars and 183 reserves, and there are 6,565 enlisted men—a totally inadequate number. There is a large reserve of about 19,000, of which over 11,000 are medical officers. It is interesting to note, for comparison, that the daily cost per head in hospital is 4.8865 dollars. The medical personnel attached to the Air Corps consisted of 52 officers and 204 enlisted men, which numbers are stated to be inadequate. Airplane ambulances are in regular use.

##### Statistics.

The mean annual strength of the army was 132,377 and the rate of admission sick 687.22 per 1,000, an increase compared with 1925 due chiefly to an epidemic of influenza. Bronchitis again heads the list of admissions, with influenza, tonsillitis, and gonorrhoea occupying the next highest places. The death rate was 3.94 per 1,000, the chief causes being suicide, drowning, and tuberculosis. The discharge rate for disability was 18.35 per 1,000, the chief causes being dementia praecox, tuberculosis, pneumonia, and automobile accidents. Suicide and dementia praecox have now headed these lists for many years.

The uniform decline in the incidence of venereal diseases is maintained, dropping from 52.25 per 1,000 in 1925 to 49.96. Syphilis 1,577, soft chancre 1,118, and gonorrhoea 3,919, show a total decrease of 483 cases. Prophylactic measures are compulsory, and neglect in using them leads to trial by court martial. Each soldier undergoes a physical examination twice a month, and pay is stopped should he lose time by contracting these diseases.

The admission rate for tuberculosis, 2.71 per 1,000, is steadily decreasing, while that for alcoholism remains at about 8 per 1,000. Of the 1,061 cases of alcoholism recorded, 749 occurred in the United States, and this number does not include cases of poisoning by wood alcohol, nor the late and remote conditions resulting from the use of alcohol. There were 42 admissions for drug addiction, a decrease of 13 compared with 1925.

The largest number of operations were for removal of tonsils, treatment of fractures, and appendicitis. Ether was the anaesthetic used in 7,634 cases and chloroform in 35.

In the Air Corps 45 deaths occurred from crashes, which represents one death for every 633 flying hours, and shows a great reduction of fatalities in relation to the flying time. During 1926 there were 78 crashing fatalities in the British Royal Air Force, but the average number of flying hours per crash is not stated in the report of that force.

As usual, the report is voluminous, containing a very large number of statistical tables and a comprehensive index.

## Ireland.

### CANCER CAMPAIGN.

At a successful meeting in support of the cancer campaign in Ireland, which was held recently in Limerick, when the Mayor presided, Professor T. Gilman Moorhead said that one person in every six over 40 years old died of cancer. During the last year there had been over 3,000 deaths from cancer in the Free State, which meant that 1 out of 1,000 in the population died from cancer. This represented an addition of 50 persons per year in the last ten years—an increase of 500 altogether. The fact had a still greater significance when it was realized that the general death rate had declined during the past twenty years by 32 per cent., the infantile death rate by 45 per cent., the tuberculosis death rate by 38 per cent., while cancer mortality on the whole was higher by 20 per cent. According to Sir Berkeley Moynihan the cancer death rate had increased fivefold within the last seventy years. There were in the Free State over 3,000 deaths from cancer and other malignant diseases annually; this probably meant that in one year there were about 9,000 persons who suffered from cancer in the Free State, and 1 in every 1,000 died from it annually. The disease tended to attack people at the very best period of their lives, when they were useful to the community. The fact that the increase was among the civilized races gave rise to hope that the cause would be discovered before long. It was most important that efforts should be made on the lines of research and education. So far the cause had eluded their efforts, but the ground was now prepared, and Professor Moorhead believed that in time someone, perhaps a Limerick practitioner, would immortalize himself by discovering the secret. It had been calculated that if the public were alive to the importance of recognizing the early symptoms the mortality could be reduced by 25 per cent., for undoubtedly cancer, in its early stages, was a local disease which could be cured. Much money would be needed if the campaign was to be carried to a successful issue, but the speaker felt confident that the people of the Free State would not lag behind other nations in facing the situation. Sir W. de Courcy Wheeler expressed the belief that the dread of cancer was to a large extent the product of ignorance of what research and investigations had already achieved, and were likely to provide, and failure to realize the number of sufferers who could be rescued with certainty. An eminent surgeon had recently published statistics which showed that over 90 per cent. of patients afflicted with cancer of the breast were about and well ten years after operation. The efforts of scientists during the last few decades had been crowned with more substantial success than the total of all the combined efforts of past ages. A point had been reached when it seemed that nothing could indefinitely impede progress towards the desired goal. Ireland could not compete with the great laboratories and vast wealth of other lands, but she wanted it known that she was ready to provide reinforcements for the army of workers already in the field. Dr. M. S. McGrath, medical officer of health, recalled that in his report to the Limerick Corporation in 1926 he had recorded that for the four previous years 177 persons had died in the city from cancer. A resolution declaring that the campaign was well worthy of support was adopted on the motion of Senator T. W. Bennett, seconded by Dr. McGrath.

### THE FORSTER GREEN HOSPITAL FOR CONSUMPTION, BELFAST.

The annual meeting of the Forster Green Hospital for Consumption, Belfast, was held on January 31st; Mr. H. V. Coates occupied the chair. It was announced that 197 patients had been admitted during the previous year, and there was a daily average of 77.74 in the hospital; the average stay was twenty-one weeks. The committee thanked Mrs. J. B. Bryson for her generous offer in respect of the installation of an artificial light outfit. It was added that a better laboratory was urgently needed. Dr. B. R. Clarke, the medical superintendent, in his report

commented on the persistence of a waiting list and the decided disadvantage of patients having to wait several weeks, in unsuitable surroundings, before admission to the hospital. There was a definite improvement in the number of early cases admitted, but unfortunately some still delayed for many months before applying for admission. Medical practitioners were recommending patients to seek sanatorium treatment at the earliest possible moment; some of the reluctance encountered might be overcome by making it known that there was less risk of infection in a modern hygienic sanatorium than was incurred by entering a public building or vehicle. Excellent educational work was being done. The principle underlying the treatment at the Forster Green Hospital was to help patients to cure themselves. Thirty-three open cases of tuberculosis had been discharged during the year after a course of sanocrysin; the results were distinctly encouraging. The usefulness of this remedy appeared to be greatest in patients who had not been ill for more than a few months. Exact information from statistics was being accumulated and would prove of great value.

## Scotland.

### BRITISH MEDICAL ASSOCIATION, EDINBURGH MEETING, 1927.

A MEETING took place in the hall of the Royal College of Physicians, Edinburgh, on February 1st, for the purpose of making a presentation to certain of the officials on whom had devolved the greater share of the organization in connexion with the British Medical Association Meeting at Edinburgh last July. Dr. A. Logan Turner, chairman of a committee which had got up this presentation, presided over a company of about a hundred medical men and friends, and referred to the great success of the meeting and the arduous labours which had been undergone in carrying out the arrangements, especially by the individuals to whom the presentations were to be made. He then tendered to Sir Robert Philip, President of the British Medical Association, a silver salver; to Mr. Alexander Miles, who had acted as treasurer for the British Medical Association Meeting, a silver rose-bowl; and to Dr. A. Forgue Hewat, who had acted as general secretary of the meeting, also a silver rose-bowl. The three recipients of the presentations acknowledged their high appreciation of the gifts.

### VICTORIA INFIRMARY, GLASGOW.

The fortieth annual report of the governors of the Victoria Infirmary, Glasgow, gives an account of the work of that institution from December, 1926, to December, 1927. During this period the total number of cases admitted was 5,130, and the mortality was 7.7 per cent. Excluding deaths within forty-eight hours of admission, the mortality was 5.4 per cent. In addition there were 3,585 minor surgical cases and accidents, and 2,535 patients received treatment at the infirmary dispensary for diseases of the nose and throat. The average daily number of patients was 328, and the average residence 22.9 days. Patients' contributions during the year amounted to £904, an increase of £169 as compared with last year. The Bellahouston Dispensary, situated in a densely populated locality on the south side of the river, does valuable work among the poor of the district, and many of the accidents occurring in the neighbouring docks, works, and warehouses received treatment there. The total number of consultations at the dispensary in 1927 was 41,343. The total expenditure for the year was £49,947 4s., being the sum required to maintain the infirmary, the dispensary, and the convalescent home at Largs. The total income fell short of that amount by £1,931 1s. 6d. The new infirmary wing—recently opened—will involve an additional annual expenditure of £14,000. Employees' contributions for the year amounted to £11,062 7s. 1d., and show an increase of £511 2s. 3d. as compared with last year. The most important event of the year was the opening of the new wing by the Right Hon. Sir John Gilmour, Bt., M.P., Secretary of State for Scotland, and

February 26th. Accommodating 2,000 patients per annum, it has reduced the waiting list from 700 to 230. Work on the auxiliary infirmary at Thorntonhall was commenced in May, and is progressing steadily. This building, when complete, will be a notable addition to an institution which already renders valuable service to the community.

#### ABERDEEN ROYAL INFIRMARY.

The 188th annual report of the Aberdeen Royal Infirmary has just been issued. The report shows that 5,260 patients had been treated in the hospital and 23,208 as out-patients, making a total increase of 1,581 over the figures for 1926. The average number of occupied beds had been 349, and the average period of residence by each patient in hospital had been twenty-six days. The ordinary income for the past year was £32,884, which showed an increase of £1,028 over the income of the previous year. Reference is made to a sum of £96 which had been obtained by the collection of tinfoil wrappings. The ordinary expenditure amounted to £32,806, an increase of £529 on that of the previous year, which is attributed to expenses in connexion with the opening of new surgical wards. The average cost per occupied bed (deducting, however, the cost of out-patient treatment) was £87 7s., compared with £91 3s. 4d. in 1926. The average cost of each in-patient treated had been £5 15s. 11d., as against £6 1s. 1d. in the previous year. The extraordinary income had amounted to £11,789, and of this £4,677 had been expended in extension of buildings and provision of new equipment. The extraordinary income and expenditure account showed at the end of the year a credit balance of £50,455, while, taking into account the valuable assets comprised in the Infirmary buildings and site, the general assets of the Infirmary stood at £145,268. The latter figures are, as it is pointed out, of importance in connexion with the Lord Provost's appeal for a new infirmary.

#### SCOTTISH BOARD OF HEALTH: MEDICAL APPOINTMENT.

The Scottish Board of Health has appointed Dr. George W. Simpson to be a medical officer in its department. Dr. Simpson is a graduate of Edinburgh University and holds the degrees of M.A., M.D., B.Sc., and the D.P.H. He was for two years senior resident medical officer at the Edinburgh City Hospital for Infectious Diseases, and was appointed assistant medical officer of health to the city of Edinburgh and principal port medical officer, Leith, in October, 1926. Since then he has been responsible for the immunization of school and other children against diphtheria and for the investigation of epidemics of infectious diseases in Edinburgh schools.

#### PARATYPHOID FEVER AT GALASHIELS.

Thirty patients suffering from an attack of paratyphoid-A fever have been admitted to the Sanderson Hospital, Galashiels. It is believed that thirteen years have elapsed since a previous case of typhoid or paratyphoid fever was notified in this town. The outbreak appears to have taken place about the first week in January. The cases all developed about the same time, and as no cases have been notified recently it appears probable that the source of infection, having been introduced from outside the town, has now disappeared.

#### CENTRAL MIDWIVES BOARD FOR SCOTLAND.

At the examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, and Dundee, out of 95 candidates entered 89 passed. Of the successful candidates 20 were trained at the Royal Maternity Hospital, Edinburgh; 27 at the Royal Maternity Hospital, Glasgow; 7 at the Queen Victoria Jubilee Institute; 8 at the Elsie Inglis Memorial Hospital; 3 at the Royal Infirmary, Dundee; 2 at the Maternity Hospital, Aberdeen; 3 at the County Hospital, Bellshill; 4 at Stobhill General Hospital; 1 at the Cottage Nurses' Training Home, Govan; and the remainder at various recognized institutions.

At a meeting of the Board held for the election of the office-bearers, Dr. James Haig Ferguson was unanimously re-elected chairman. Dr. Robert Cochrane-Buist was elected deputy chairman, and Sir Archibald Buchan-Hepburn, Bt., was re-elected convener of the Finance Committee. The

meeting appointed other committees and also examiners for the ensuing year, and approved, subject to inspection by the Board, the list of recognized institutions, with the teachers attached thereto, for the training of midwifery nurses.

## England and Wales.

#### CENTENARY OF THE ROYAL FREE HOSPITAL.

A THANKSGIVING service for the centenary of the Royal Free Hospital will be held in St. Andrew's Church, Holborn, on Sunday morning, February 19th, at 11. The preacher will be the Bishop of Willesden, and the service will be attended by the Lord Mayor of London and the Mayors of Holborn, Finsbury, and Islington. This church has been chosen for the service owing to the fact that the foundation of the hospital was due to a pathetic incident which happened in its precincts, and is now commemorated by a memorial tablet in the nave. On a cold winter night, in 1827, Dr. William Marsden discovered a girl dying of disease and starvation on the church steps. He was unable to obtain admission for her to a hospital owing to the lack of a subscriber's letter of recommendation, and, two days later, she succumbed. Dr. Marsden determined, therefore, to found a hospital which should admit sick persons freely and without delay. The work began humbly in February, 1828, in a small house in Hatton Garden, and was transferred, in 1842, to Gray's Inn Road. Since then the institution has grown into a hospital with 268 beds and a great school of medicine for women.

#### COMPARISON OF TUBERCULOSIS RECORDS.

The Ministry of Health has published an analysis (Memo. 131/T) of the reports received from tuberculosis officers for the year 1926, in order that comparison may be rendered possible between different areas as regards the efficiency of the various schemes of local authorities—namely, county councils and joint committees, county borough councils and metropolitan borough councils. The figures given in the reports have been reduced to a common standard, being expressed either as percentages or in proportion to some common factor of particular significance in connexion with the incidence of tuberculosis—such, for example, as the number of deaths from this cause in each area during the year. The suggestion is made that local authorities and their officers should compare the figures in their own areas with those relating to others of similar size and character. This may result in the extension or varying of the schemes in certain directions, and may also lead in some cases to the recognition of possibilities of effecting economy. Special points which are elucidated by these statistics are: the varying efficiency of notification and of the revision of notification registers; the proportion of the total tuberculous population in each area dealt with under the tuberculosis scheme; the extent of the examinations of suspected cases and of contacts; the amount of delay in diagnosis; and the degree of utilization of sputum examinations and x-ray investigations. The measure of the co-operation between tuberculosis officers and general practitioners is indicated for the different areas, and also the amount of supervision exercised over tuberculous patients in their own homes. In some areas it is shown that there has been failure to arrange effectively for the co-ordination of tuberculosis officers and insurance practitioners in domiciliary treatment. The nature and extent of the residential treatment provided in the different areas is demonstrated, and it is suggested that comparison of this memorandum with the recommendations in paragraphs 2 to 5 of Circular 280, issued on January 17th, 1922, may facilitate greater economy in making use of the available residential accommodation, due regard being paid to the stage of the disease and the response to treatment in each individual case.

#### WOMEN MEDICAL OFFICERS AT LONDON MENTAL HOSPITALS.

The Mental Hospitals Committee of the London County Council, from experience gained in the employment experimentally at one of the mental hospitals of a woman assistant medical officer for special duty in connexion with

women patients, proposes to extend the employment of women medical officers to other mental hospitals where there are facilities for their accommodation: The recognized scales of remuneration for junior assistant medical officers do not specify that they are applicable to men alone, but as they were fixed with only a male staff in contemplation, scales of remuneration for women assistant medical officers have to be determined. It is proposed, therefore, that authority should be given for the application to women of the scale of remuneration laid down for assistant medical officers below the rank of fourth in the mental hospital service. This at present is £300 a year, increasing by annual increments of £25 to £400. With the existing temporary additions approved in 1920 this means a total remuneration at the minimum of £423, and at the maximum of £547. The Finance Committee of the council, before concurring, has inquired what additional expenditure in respect of structural alterations and employment of domestic staff the appointment of women as assistant medical officers would entail, and has found that only at three hospitals (Hanwell, Horton, and Long Grove) could women be employed without additional expenditure for these purposes, and at each of these hospitals not more than two such women. Accordingly the Mental Hospitals Committee has agreed not to appoint women medical officers except for duty at these three hospitals, and to consult the Finance Committee if at any future date it should be thought advisable to extend the appointment of women at these or other hospitals under circumstances which call for additional expenditure.

## Correspondence.

### HOSPITALS AND ROAD ACCIDENTS.

SIR,—With reference to your article on hospitals and road accidents at p. 192 of the *BRITISH MEDICAL JOURNAL* of February 4th, I think the following information may be of interest to your readers.

On December 6th, 1927, the case of *Lewis v. Champkin* was tried at the Birmingham Assizes before Mr. Justice Sankey. The plaintiff Lewis claimed damages for injuries sustained as the result of a motor accident. The jury awarded damages, including the hospital charges and the surgeon's fees. In his address to the jury the judge stated that both the hospital charges and the surgeon's fees were fair and reasonable and not excessive in any way, and that the surgeon and the hospital could not be expected to look after the plaintiff and allow the defendant to escape liability if the jury found that the defendant was liable to pay damages.—I am, etc.,

Kidderminster, Feb. 5th.

J. LIONEL STRETTON.

### FATALITY RATES OF SMALL-POX.

SIR,—As several persons, notably Dr. Killick Millard, have pointed out, Dr. Garrow's figures given in his letter of January 14th are based upon the fallacy of comparing statistical incommensurables. As Dr. Garrow well knows, there have been two distinct types of small-pox occurring in England during the last few years; the vast majority have occurred in the unvaccinated populations of the Northern and Midland counties, and were of the mild type—variola minor, if he likes so to term it—whilst a very small number of a severe type—variola major—have occurred in the South of England, due to infection introduced from France, Spain, etc.

This distinction is not apparent in the tables published in the annual reports of the chief medical officer to the Ministry of Health, though doubtless the necessary information is available at the Ministry. By comparing the information in these tables, from which he quotes, with the accompanying text, and with the figures given in Table 40 of the Annual Statistical Reviews of the Registrar-General, I have been able to identify nearly all the deaths. In this manner I obtain the following table of deaths in England during the years 1923 to 1926.

Age.	Vaccinated.	Unvaccinated.
Under 15 ...	0	17 (probably all Northern).
15 to 30 ...	1 (? Northern)	2 (1 Northern, 1 Southern).
Over 30 ...	12 (5 Northern, 9 Southern)	2 (1 Northern, 1 not identified).
Total ...	13	21.

By "Northern" is meant the Northern and Midland counties as defined by the footnote to Table 4 of the Registrar-General's Statistical Reviews, less Middlesex, Herts, and Essex, the remainder being the Southern counties.

Assuming, then, that all the deaths in the Southern counties were deaths from variola major, we may deduct them from the total deaths; this assumption is quite valid, as these deaths can be identified from the text; identification of the cases is not easy, but as those occurring in the South of England were very few (about 80), they may be neglected statistically. The amended table is as follows:

Ages.	Vaccinated.			Unvaccinated.		
	Cases.	Deaths.	Fatality Rate.	Cases.	Deaths.	Fatality Rate.
0-15 ...	28	0	—	10,709	17*	0.158 ± 0.026
15-30 ...	392	1	0.25 ± 0.17	5,296	1	0.019 ± 0.013
30 and over	3,618	3	0.08 ± 0.03	1,713	2	0.117 ± 0.070
Total ...	4,038	4	0.10	17,718	20	0.112

\* Ten were under 1 year old.

These figures are probably accurate as far as they go, except that the small number of cases of variola major in the Southern counties are included. The table gives the fatality rates from mild small-pox in the vaccinated and unvaccinated, the advantage being in favour of the vaccinated except at ages 15 to 30 years, where, the rates being based on a single death in each class, no deduction is possible from such meagre data. The probable error in all classes except the youngest class of unvaccinated is high. Even when corrected there is a further fallacy, as two of the three deaths among the vaccinated at ages over 30 years were of persons aged over 70, whilst only one death at those ages occurred among the unvaccinated. It is well known that small-pox fatality rises steeply in the later years of life.

The data do not form a basis of comparison for the fatality rates in variola major among the vaccinated and unvaccinated, but this may be ascertained from the data of other epidemics—for example, those given in Table II of Dr. W. Hanna's *Studies in Small-pox and Vaccination*, published in 1913.—I am, etc.,

Liverpool, Feb. 4th.

G. O. STALLYBRASS.

### RICKETS, IRRADIATED ERGOSTEROL, AND ULTRA-VIOLET LIGHT.

SIR,—Irradiated ergosterol is now on the market, and great claims have recently been made for it in the lay press as to its power of "stamping out" rickets. In the *Times* of January 29th it is stated that "it is recognized now that children and expectant mothers should be irradiated with ultra-violet light, but *this new discovery improves upon that treatment.*" (Italics are mine.)

Well, does it? I sincerely hope so, but so far as I know, that still remains to be proved. I do not doubt that irradiated ergosterol may cure the disease rickets, just as cod-liver oil may do, but in its practical application to the masses of rachitic children in the larger industrial areas cod-liver oil has failed to stamp out rickets. Irradiated ergosterol may be easier to digest, and therefore may be better, but until this is proved I should be very doubtful

about abandoning the sure method of ultra-violet treatment in its favour. It should be remembered that exposure of rachitic children to ultra-violet light not only cures the rickets, but has many other beneficial effects which irradiated ergosterol presumably cannot claim, the most important being the great improvement of the child's general health and its release from the dangerous catarrhal state.

In another respect, however, the *Times* article is valuable. It draws attention to the fact that expectant mothers should be irradiated. How many maternity hospitals, or even ante-natal clinics, have installed lamps for the purpose? Have maternity hospitals no function beyond the mere delivery of the child? During the pre-natal stage the child's body is being made or marred, and those who undertake the care of this period have surely a responsibility for the future physical condition of the child.—I am, etc.,

H. STANLEY BANKS,  
Medical Superintendent, Leicester Isolation  
Hospital and Sanatorium.

February 1st.

#### TREATMENT OF ACUTE PNEUMONIA.

Sir,—Is not the present "curability [*sic*] of acute pneumonia in adults" rapidly becoming farcical? Hardly a week passes without some enthusiast writing that he has not met with a death since using this or that remedy. Is there some factor in common to all these drugs which explains the apparent inconsistency, or do they all cure? Or does the patient recover in spite of our remedies, as Dr. Gee used to say of arsenic in chorea? I am old enough to remember the value of ammonium carbonate; then came an infallible mixture of effervescent quinine; somebody recently wrote of the great value of sodium bicarbonate; another finds calomel in small doses rarely fails, whilst another sedulously keeps the bowels inactive or doesn't bother about them! Now it is injection of sodium nucleinate. Dr. Hearne puts 1 in 7,000 potassium permanganate into the rectum and believes in a pneumonia vaccine! A few years ago there was not much chance without salicin, and I am told now by a much respected physician that few die with a mixture of sodium iodide, ipecacuanha wine, and ammonium citrate!

It is all very strange, not to say tragi-comic. Meanwhile the disease still figures in the death roll. Have such fatalities been wrongly treated, or would the patients have recovered if one of these specifics had been used? I suggest that with the necessary notification, and death certificate—if perchance one has to be given—a confidential report of the treatment be also given. We need skilful logicians to help us with our reasoning. With such wealth of material some sort of precise knowledge should result.

Few things in medicine, I venture to think, are more fallacious than the reports of us men in general practice. They deal so hugely in impressions. The busiest and most experienced men find no time for accurate notes—pace the late Sir James Mackenzie; the youngsters are carried away by the glamour of their last success (should I say bit of luck?); while the hospitals see the worst and feeblest cases. It seems to me that, with the exception of certain vaccines not dependent on aught but hypothetical germs, most of the remedies are harmless, provided the hypodermic needles are clean, sharp, and strong, and they spare the buttocks.

I suppose how most of us would like to be treated is something like this: in a cosy, well-aired room, with a genial not too officious nurse, peaceful domestic surroundings, and a kind middle-aged, restful, keen-eyed physician. If there were pain, and I could be got at easily, I would submit to a poultice or antiphlogistine, not too hot, and expect some morphine, and some medical for sleep. I should like plenty of lemonade, my mouth cleaned, a little champagne or cider, lemon sponge, jelly, junket flavoured with rum, and possibly something like honey, glucose, or malt extract to prevent "acidosis." Seeing how common is this "acidosis" I don't think I should mind some calomel (if I were promised not to be disturbed too much by a bed-pan), and some sodium bicarbonate more or less frequently.

Mr. Shaw, in one of those valuable gibes of his, says how often he has noticed the only common factor in all the prescriptions of a patient who had gone the round of Harley Street was sod. bicarb. gr. x, t.d.s.! So let us have sodium bicarbonate as a drug by all means; and I would let him give me a little oxygen if the room got stuffy, and possibly some strychnine if the doctor looked sad at my objection. To some I find strychnine is anathema. What an interesting view of things one gets at 60!—I am, etc.,

Ilminster, Somerset, Jan. 29th.

W. H. MAIDLOW.

#### IODINE IN THE TREATMENT AND PREVENTION OF GOITRE.

Sir,—In reference to a note by me (1927, vol. ii, p. 361) on the use of iodine in salt, authorized by the New Zealand Government for the prophylaxis of goitre in children, Sir James Barr (1927, vol. ii, p. 470) has written to state that he has been unable to detect iodine in iodized salt by his method of analysis. This is quite possible, but the Department of Health in New Zealand states that "the Dominion analyst, who regularly examines samples of salt as sold on the New Zealand market, adopting the method recommended by Fallenburg, the well known worker, can estimate the iodine with accuracy, and the examination of 'Cerebos' and 'Windsor' salt, the two well known brands on the New Zealand market, shows that the iodide is evenly distributed and is present in the requisite proportions."

A study of the literature shows that the problem of goitre is by no means solved, and that there is still doubt even as to the relationship of the disease to iodine deficiency. At an international conference on goitre held recently in Switzerland the benefits of iodine prophylaxis were questioned by some speakers. On the other hand, Swiss and Austrian investigators claim that iodized salt in the proportion of 5 mg. of potassium iodide to 1 kilo of salt (1 in 200,000) has proved of definite value. It can be said with certainty that there is no evidence that salt containing iodide in these proportions does any harm, while there is a certain amount of evidence that it may do good. As goitre is prevalent in children in New Zealand the considerations outlined above are a sufficient justification for the use of iodized salt in this Dominion.

The Swiss Goitre Commission recommended that salt containing one part of potassium iodide to 200,000 parts of salt should be used, but this is stated to contain possibly too much iodine. The use of one part of potassium iodide to 250,000 parts of salt authorized in New Zealand gives a margin of safety. In this country the recommendation of the commission that uncontrolled purchase of iodine preparations by the public should be prohibited was anticipated, and mainly for the reason that there is sufficient evidence to show that the administration of iodine in comparatively large doses to patients in adult life suffering from simple goitre may convert simple goitre into toxic goitre, greatly aggravating the disease.—I am, etc.,

YOUR NEW ZEALAND CORRESPONDENT.

December 5th, 1927.

#### QUININE IN OBSTETRIC PRACTICE.

Sir,—The letter by Dr. Hewetson on this subject in your issue of January 28th (p. 157) deserves the careful attention of all engaged in this work. The method was suggested to me five years ago by Dr. Philip Jones of Coleford, Somerset, since when it has been used in nearly every case in my own practice in which careful ante-natal examination permitted a diagnosis of "normality." (N.B. Occipito-posterior positions were included as normal.) Between us we have used the method in just over 300 cases, and have so far failed to discover any disadvantages. The details of the quinine administration are not identical with Dr. Hewetson's routine, but the principle is the same. We have aimed at giving  $1\frac{1}{2}$  grains of quinine three times daily for the last three weeks of pregnancy, though a few patients complained of cramp-like pain in the abdomen and had to be given half this dosage.

The following advantages of the method have been noted:

1. Patients frequently volunteer the information (without any leading questions) that their general health has greatly improved since starting the medicine.

2. Labour appears to be definitely shortened. The average duration from the onset of "real pains"—as opposed to "niggling pains"—was about six hours for primiparae and three hours for multiparae.

3. Retraction of the uterus after labour was uniformly good.

We can say with conviction that in these cases there was no increased tendency to retained placenta, perineal laceration, precipitate labour, premature labour, or "after-pains." In its very insistence on ante-natal work the method is, surely, deserving of attention.—I am, etc.,

DOUGLAS A. MITCHELL, M.D. Lond.,  
F.R.C.S. Ed.

Bath, Jan. 30th.

#### FOREIGN BODIES IN THE STOMACH.

SIR,—Dr. S. Gilbert Scott's interesting note on a method of dealing with a swallowed object (January 28th, p. 133), and his instruction to his patient "to go out and eat as big a lunch as he could without any fluids," brought to my mind another useful "tip" in dealing with such emergencies.

This was suggested some sixty years ago by my father, the late Dr. George Dickson of Edinburgh. He, when a boy, used to keep hawks, and noted how the bones of the birds and mice which they swallowed were passed neatly wrapped up in feathers or fur. He had several cases of patients who had swallowed their sets of false teeth, and he ordered them to take large quantities of what he called "thread-porridge." A reel of thick thread or wool was incised longitudinally whilst still rolled up, giving a large number of short pieces of the thread or wool. This was then stirred up in thick porridge and administered to the patient. A day or two later the dentures, some of them with awkward sharp projections, were passed naturally from the bowel, wrapped up in the threads.

He communicated this method to a dental journal of the period, but I have no note of the exact reference or of the date, which was, of course, long before the days of x rays. Quite a number of similar cases successfully treated by Dr. Dickson's "thread-porridge method" were reported soon after he recorded his own cases.—I am, etc.,

W. E. CARNEGIE DICKSON, M.D., B.Sc.,  
F.R.C.P. Ed.

February 5th.

Pathologist to the West End Hospital for Nervous Diseases, London.

#### SHOCK AND ABORTION.

SIR,—The subject of abortion is not of great or general interest, but the causation of shock is of universal importance, while its pathology is obscure and its morbid anatomy apparently is nil. In the recent case of R. v. Palmer, reported in the BRITISH MEDICAL JOURNAL of February 4th (p. 202), the evidence suggests that fatal shock can be set up by the distension of the uterus by an injection of soapy water. Yet on page 193 of the same issue is an account of 30,000 intrauterine injections. It is significant that this most interesting report from Dr. Hobbs of Kensington closes with a note of warning as to the rate at which the glycerin is to be injected.

Is it possible that the shock depends, not on the nature of the interference, but on the rapidity with which the tension in the cavity of the uterus is increased? Is this analogous to the rise in blood tension which occurs in angina pectoris? In the little known work of Professor Vibert, *Médecine Légale* (1911 edition), at page 110 is an account of a case in which a fairly skilled abortionist was just beginning to give an intrauterine injection when the patient complained of distress, asked the operator to stop, became unconscious, and died in a few minutes. The post-mortem examination was negative. At page 467 Vibert gives short notes on six other cases, all fatal, with little or no post-mortem signs. He published in 1893 an

account of the "affaire Thomas," in which a woman of this name seems to have given details of her proceedings, from which the first of these reports is taken.

It does not appear from Vibert's book that the introduction of a sound has, in his experience, been followed by sudden death, so that it is likely that something more than the mere introduction of a foreign body such as a sound, or fluid such as glycerin, is needed to set up uterine shock.—I am, etc.,

London, Feb. 2nd.

SENEX, M.B., D.P.H.

#### Medico-Legal.

##### A BOGUS DOCTOR.

THERE will be general agreement with Alderman Sir George Truscott's view that the maximum fine of £20 which can be inflicted upon any person—to quote Sec. 40 of the Medical Act, 1858—"who shall wilfully and falsely pretend or take or use the name or title of a physician, doctor of medicine . . ." is totally inadequate to meet so serious an offence. The alderman was dealing summarily at the Mansion House with a carpenter, twice convicted of fraud, who posed as a medical practitioner at Wardrobe Chambers, Queen Victoria Street, where his consulting room was fitted up with electrical apparatus, his door bearing the inscription "Dr. Boyd Faulkner, M.D." When the Registrar of the General Medical Council wrote in November last inquiring about his qualification, Faulkner replied that he was an American subject and was registered with the American Medical Association, having taken a Federal degree at New York in 1914, and also the degree of D.Sc. at Edinburgh in 1910. He signed himself "Sydney Boyd Faulkner, M.D., U.S.A." His answers to the magistrate's questions were distinctly ingenuous. Apparently he had no particular wish to practise medicine, but rather "nature cure," and he had held himself out as a doctor for the purpose of advertising himself as a "nature cure" specialist. As the magistrate said, such an admission showed the necessity for protecting the medical profession and the public whom they served against such persons as Faulkner, with no recognized training or qualifications, and possessing, moreover, so ill a character that the police could find no one willing to act as surety. The consequence was that a term of two months' imprisonment was fixed in default of payment of the £20 fine and 10 guineas costs. Sir George Truscott added that it was ridiculous that magistrates were not given more powers in such an important matter, where not only the medical profession but the public were seriously concerned.

#### Obituary.

CLAUDE WILLIAM SCOTT SABERTON, M.D.,  
D.M.R.E. (Camb.).

THE death occurred at Bournemouth, on January 16th, of Dr. Claude Saberton, who was well known as a radiologist both in Bournemouth and Harrogate. The son of the late Dr. Saberton of Manchester, he received his medical education at the Manchester University, graduating M.B., Ch.B. in 1901, and taking his M.D. four years later. Some years after graduation he devoted his attention to radiology, and in association with Dr. Fowler practised in Bournemouth, where he was on the staff of the Royal Victoria and West Hants Hospital. After the war he settled at Harrogate and in a few years built up a large practice, retiring from active work owing to ill-health.

A Harrogate colleague writes: During the all-too-short time that Saberton's health allowed him to follow in this town that branch of practice to which he had for some time devoted himself he gained a deservedly high place in the esteem both of the profession and the public. He brought to his work sound practical and theoretical knowledge, boundless energy, and unflinching optimism, so that whether at the Infirmary and the Royal Bath Hospital (he was appointed to the honorary staff of both Institutions soon after coming to the town) or in private practice it

gained rapid and ever-increasing recognition. He was one of the first to install at his private clinic an apparatus for deep x-ray therapy, spending a holiday in Erlangen so as to gain first-hand knowledge of the method. He wrote a book on diathormy, contributed several papers to the journals, and took the D.M.R.E. of Cambridge in 1921. Such a record is all the more remarkable when it is remembered that during the latter part of his time here he was constantly harassed by symptoms of the disease which was soon to cause his retirement from active work, and in a few years his premature death. Whilst honouring these professional accomplishments his friends are glad also to remember the personality and character which lay behind them. His transparent honesty, wide sympathy, generosity, and perhaps above all his exemplary courage in a constant fight against physical disability, which the logic of his medical knowledge must at times have warned him was a sadly unequal one, will make his memory for long a happy and inspiring one to those who knew him best, and their sympathy goes out to the devoted wife and daughter who survive him.

We regret to announce the death, on January 25th, of Dr. ROBERT ARTHUR MILLIGAN of Northampton, aged 69. He was a native of Deene, and received his early education at Clevedon College, situated then in Abingdon Street, Northampton, and at the age of 17 became a pupil at the Northampton Hospital. In 1876 he entered Guy's Hospital Medical School and took the diplomas of M.R.C.S.Eng. in 1881 and L.R.C.P.Lond. in 1884; he became M.D.Durh. in 1900. After serving as house-surgeon at Guy's Hospital, registrar and chloroformist at the Evelina Hospital for Children, and as clinical assistant at Bethlem Hospital, he returned to Northampton in 1884 on being appointed house-surgeon to the Northampton General Hospital, and his connexion with that institution continued for forty-three years until he retired in January, 1927. On his retirement from the active staff of the hospital he was presented with a cheque of £453 and an album containing the names of the subscribers. He had a large practice in Northampton and the surrounding districts, and won the esteem and confidence of his patients. During the war he served at the Military Hospital at Cambridge, and was awarded the O.B.E. in recognition of his services. Dr. Milligan was a pioneer of the ambulance movement in Northampton, and was for some years ambulance instructor to the Northampton division of the county constabulary. He took a keen interest in municipal affairs, and was a member of the Northampton Town Council for twenty-three years, and a member of the Public Health Committee, of which he was at one time chairman. He was appointed to the magisterial bench in 1906. Dr. Milligan was for many years a member of the British Medical Association; from 1892 to 1925 he was a member of the Committee of Management of the South Midland Branch, was president of the Branch in 1897, and treasurer from 1899 to 1922.

Dr. GERALD FITZGERALD, who died on January 28th, received his medical education at Edinburgh, where he graduated M.B., C.M. with first-class honours in 1890, and obtained the Freeland-Barbour Fellowship in the following year. He proceeded M.D. in 1919. He had held the posts of assistant to the professor of clinical medicine in Edinburgh, senior resident physician to the Edinburgh Royal Infirmary, and resident surgeon to the Royal Maternity Hospital; he was also president of the Edinburgh Royal Society of Medicine. He abandoned teaching and research at what seemed to be the outset of a very promising post-graduate university career, and established himself in the City of London, where he gained a leading place in life assurance work. He was medical officer of the Scottish Equitable Assurance Society, the Scottish Provident Institute, the Edinburgh Assurance Company, and other corporations, and also chief medical officer of the Royal Mail Steam Packet Company. His decisions in cases of difficulty were regarded as authoritative in the insurance world, and he took a prominent part in the

work of the Life Assurance Medical Officers' Association. During the war he devoted himself to the medical side of recruiting. He was a member of the British Medical Association and a Fellow of the Royal Society of Medicine. Dr. Fitzgerald was a man with exceptionally wide and varied interests. He was a devoted student of Scottish folk-lore and history, a keen member of the Highgate Golf Club, and an ardent worker in the Highgate Presbyterian Church. His death is regretted in the City of London and especially in Highgate, where he accomplished much quiet and unostentatious social service. He leaves a widow and two daughters.

Dr. DAVID WOLSELEY SCOTT, who died at his residence at Bryn, Port Talbot, on January 13th, at the age of 65, received his medical education at Anderson College, Glasgow. He obtained the diplomas L.R.C.P., L.R.C.S.Ed., L.R.F.P.S.Glas., and L.M. in 1887. Dr. E. Walsh writes: Dr. Scott in his forty years of general practice ever maintained the highest tenets of his profession. Of a most kindly and generous disposition, his relations with his colleagues and patients were of the most friendly nature. He was a member of the British Medical Association. He leaves a widow.

Dr. PHILIP JAMES of Senghenydd died on January 28th, aged 73. He received his medical education at Guy's Hospital Medical School, and took the diplomas of L.R.C.P.Ed. and M.R.C.S.Eng. in 1878. He had practised at Senghenydd for thirty-five years, and before that at Porthcawl and Pontypridd. It was while in practice at the latter place that Dr. James assisted in the rescue work at the colliery explosion there in 1877, and he was one of the eight recipients of the bronze medal awarded by the British Medical Association for heroic conduct, self-denial, and humanity.

Dr. LEUIS ROBINSON died at Folkestone on February 5th as the result of an accidental gunshot wound. He received his medical education at St. Bartholomew's Hospital, and took the diplomas of M.R.C.S.Eng. and L.S.A. in 1883; he graduated M.B. Durh. in 1887 and M.D. with first-class honours and gold medal in 1891. He had served as house-surgeon to the Stockton and Darlington Hospitals, and subsequently became surgeon to the Millor Hospital. For upwards of thirty years he practised at Streatham, and on his retirement some six years ago went to live at Poynings, near Brighton; four years later he removed to Folkestone. He was the author of *Wild Traits in Dumb Animals*, and contributed articles on "Reflexes" to the *Dictionary of Psychological Medicine*, 1892, on "Observations on hair tufts" to the *Journal of Anatomy and Physiology* in the same year, and on "The chin in relation to articulate speech," which appeared in the report of the Smithsonian Institute, Washington, for 1913.

The following well known foreign medical men have recently died: Professor ALFONSO MONTEFUSCO, director of the Ospedale Cotugno for infectious diseases at Naples, and a prolific writer on fevers; Dr. FRANCES WELD PEABODY, professor of medicine at Harvard University, aged 45; Dr. EDOUARD LAGUESSE, professor of histology at Lille University; Madame KLUMPKA-DEJERINE, a prominent Paris neurologist and widow of Professor Dejerine; Dr. JOHN WESLEY BOVÉE of Washington, a prolific writer on gynaecology and a former president of the American Gynaecological Society; Dr. VLADIMIR VON BECHTEREV, professor of neurology and psychiatry at Leningrad and a pioneer in experimental neuropsychology, aged 73; Professor NEGRI, director of the institute of neuropathology at Turin University; Dr. WILLIAM GILMAN THOMPSON, emeritus professor of medicine at Cornell University, New York, and author of a textbook on medicine, aged 70; and Dr. THOMAS CASPAR GILCHRIST, professor of dermatology at Maryland University School of Medicine, and dermatologist to Johns Hopkins Hospital, aged 65.

## The Services.

### ROYAL NAVAL VOLUNTEER RESERVE OFFICERS' DECORATION.

The Royal Naval Volunteer Reserve Officers' Decoration has been conferred upon Surgeon Commanders T. Turner and A. E. W. Hird.

### DEATHS IN THE SERVICES.

Lieut.-Colonel Robert Tilbury Brown, C.M.G., D.S.O., R.A.M.C. (retired), died at Hatherloigh, Devon, on January 21st, aged 54. He was born on June 26th, 1873, the son of Surgeon-Lieut.-Colonel Robert Ross Brown, V.D., J.P., of Strood, Kent, and was educated at the King's School, Rochester, at Guy's, and at Durham University. He took the M.R.C.S. and L.R.C.P. Lond. in 1896, and the M.B. and B.S. of Durham in 1899; also subsequently the M.D. Durh., with a gold medal, in 1904; and the D.P.H. of the Irish Colleges in 1902. From 1894 to 1900 he served in the 1st Kent Artillery Volunteers as lieutenant, and then captain, and from 1896 to 1900 was deputy medical officer of health for Strood. Entering the R.A.M.C. as lieutenant in 1900, he attained the rank of lieutenant-colonel in 1917, and retired on August 18th, 1926. From 1902 to 1926 he was specialist in bacteriology in the laboratory at Lucknow, and from 1906 to 1913 sanitary officer in the Eastern Command, India, and Burma. When the recent great war began he served as D.A.D.M.S. in East Africa in 1914-15, and as D.A.D.M.S. at general headquarters in 1916; and from 1916 to 1919 as an A.D.M.S. in France. During this period he was mentioned in dispatches four times, in the *London Gazette* of June 22nd, 1915, June 30th, 1916, March 7th, 1918, and October 7th, 1918, and received the D.S.O. in 1916 and the C.M.G. in 1918, and also was made a Chevalier of the Order of Leopold of Belgium. After the war he was in command of the Herbert Hospital at Woolwich, in 1919-21, was senior medical officer in Ceylon in 1922-24, and S.M.O. at Borden in 1925-26, till his retirement. He was the author of several papers, chiefly on sanitary matters, published in the *Journal of the Royal Army Medical Corps*. In 1904 he married Pauline, daughter of Mr. F. Normandy, barrister-at-law.

Lieut.-Colonel Paxton St. Clair More, Bengal Medical Service (retired), died suddenly at Bournemouth on January 8th, aged 60. He was born on June 14th, 1867, the son of Dr. James More of Rothwell, Northampton, and educated at Edinburgh, where he graduated as M.B. and C.M. in 1891. Entering the L.M.S. as surgeon lieutenant on January 30th, 1893, he became lieutenant-colonel after twenty years' service, and retired on November 1st, 1923. He served in the Chitral campaign of 1895, when he took part in the relief of Chitral, and received the Frontier medal with a clasp; and in the great war of 1914-18, when he was mentioned in dispatches in the *London Gazette* of June 11th, 1920, and received the O.B.E. on June 3rd, 1919.

## Universities and Colleges.

### UNIVERSITY OF LONDON.

#### Course in Mental Deficiency.

A course of lectures for medical practitioners on mental deficiency, and on the medical instruction, has been arranged by the Board in co-operation with the Department for Mental Welfare. The course, lasting from May 14th to 19th, is intended for qualified medical practitioners, and more especially for those engaged as certifying officers to local authorities under the Mental Deficiency Act, 1913, as school medical officers, or as medical officers of institutions. The course will be based on the requirements of the syllabus for the University of London diploma in psychological medicine. Inquiries should be addressed to Miss Evelyn Fox, care of University Extension Department, University of London, Imperial Institute Road, South Kensington, S.W.7.

### NATIONAL UNIVERSITY OF IRELAND.

At its meeting on February 3rd the Senate had under consideration the reports of the Examiners upon the results of the pre-registration examination in physics and chemistry, December, 1927, and the M.B., B.Ch., B.A.O. degrees, January, 1928, and awarded passes, etc., in connexion therewith.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At a meeting of the President and Fellows of the College, held on February 3rd, the following registered medical practitioners were admitted by the President: as Member, J. R. Tobin; as Members and Licentiates, D. Moriarty, S. Simms, E. Keelan; as Licentiate in Midwifery, A. Barr.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### Opening of the New Session.

THE King opened Parliament on February 7th. The customary ceremonial was observed, but the Queen was absent. In the Speech from the Throne one passage ran: "Measures will be presented to you for giving effect to certain recommendations of my Commission on National Health Insurance." Other bills were announced for amending the law relating to parliamentary and local government franchise, for increasing the credit facilities of persons engaged in agriculture, for amendment of the Companies Acts, for the reorganization of certain of the Departments in Scotland, and for amending the laws relating to the Supreme Court of Judicature and to the Metropolitan Common Poor Fund. Announcement was made that Ministers were inquiring into the possibility of affording some relief to the producing community from the burden of rates.

Neither the Factories Bill nor the Poor Law Bill was mentioned in the King's Speech. This stated that "bills dealing with other measures of importance will be introduced and proceeded with as time and opportunity allow." Following the mover and seconder of the Address in the House of Commons in reply to the Speech, Mr. Ramsay MacDonald said that the domestic programme outlined by the Government was notable for its omissions. There was the instance of the Factories Bill. That measure had been promised again and again. They were told last year that the bill would be in the Government's programme this year. The Home Secretary and the Prime Minister had said so, but now, apparently, the Home Secretary was going to keep his promise by introducing it in another year.

Mr. Lloyd George, referring to the promised measure on National Health Insurance, assumed that it would deal with the recommendations of the Commission which reported about a couple of years ago, and which was appointed by the late Minister of Health. He would like to know whether there was any cash in that. Was the Chancellor of the Exchequer going to pay back the money which he had extracted? [Mr. Churchill shook his head at this question.] Mr. Lloyd George: Then I can tell him that unless he does so those recommendations will be of no use at all. They will be like an engine without petrol; they will not march, they will stick. The only recommendations of the slightest value in the Commission's report are in regard to additional benefit. Some of those recommendations are invaluable, but they all mean more cash, and I do not believe that that cash is available now. Can the Minister of Health get the money back which the Chancellor of the Exchequer has taken away? The Chancellor of the Exchequer just now shook his head very emphatically. I am afraid that he is going to win on this occasion, and I do not look forward to this bill with any sort of satisfaction; nor will anybody else.

Mr. Baldwin said that he was not sure if Mr. Lloyd George had asked if there was any "catch" or any "cash" in the proposed Health Insurance Bill.

Mr. Lloyd George said that he used the word "cash."

Mr. Baldwin: There is neither "cash" nor a "catch" in the bill. I am told that it deals purely with the machinery, which will facilitate very much the working of the Act, and it will neither cost the Exchequer anything nor bring anything into their funds. Continuing, Mr. Baldwin spoke of the hope of the Government to have an autumn session. With regard to the Factories Bill the Government regretted very much that in the circumstances there was no possibility of getting through any bill which might be regarded as controversial between now and the end of July. He hoped, if they were able to begin a new session, as they intended, in November, that that bill might be dealt with before the end of next session.

Mr. Templeton, in seconding the Address in the Commons, said he had received an assurance that the promised proposals for the reorganization of Departments in Scotland would not place any of them under Whitehall.

In the debate on the motion for the Address in the House of Lords on February 7th Lord Salisbury, on behalf of the Government, replied to criticisms at the absence of the Factories Bill from the Government's legislative programme. He explained that, owing to the shortness of this session and the fact that the Government hoped to prorogue at the end of the summer and start a new session in November, they were not now proceeding with the Factories Bill. Their lordships, however, must not think that the Government had abandoned the bill. They hoped that it would be one of the bills, perhaps the principal one, which would get a second reading before Christmas in the new session.

In Part II the evidence taken by the Commission on the constitution and extension of county boroughs was summarized; and Part III gave the conclusions and recommendations of the Commission on this subject. The minutes of evidence taken before the Commission are being published in parts from time to time. The latest to appear is Part IX, being the evidence given on behalf of the Ministry of Health and other Government departments during June and July, 1927; it is published by H.M. Stationery Office at 6s. net.

THE KING has appointed Dr. Donald P. Wailling, a medical officer of the Leeward Islands Medical Service, to be an official member of the Executive Council of the Presidency of the Virgin Islands.

As announced in our advertisement columns the Grocers' Company are offering scholarships of £300, with an allowance for cost for apparatus and other expenses, for the encouragement of original research in sanitary science. The scholarships are tenable for one year, but renewable for a second or third year. The next election will be held in May. Forms of application and further information may be obtained from the clerk to the Grocers' Company, Grocers' Hall, London, E.C.2.

AN interesting article by Dr. R. T. Williamson on Captain James Cook, R.N., F.R.S., and his contribution to medical science has appeared in the January number of the *Journal of the Royal Naval Medical Service*. In it Dr. Williamson points out the value of the advances made by the great navigator in the dieting of sailors. Up to his time scurvy invariably appeared amongst the crews of ships undertaking long sea voyages. How this remarkable man, self-educated and self-made, found the means to prevent this dread disease will be read with great interest, as showing how the empiricism of a sea-captain 150 years ago is justified by the biochemistry of to-day.

DURING last month the Hospital Saving Association enrolled 19,424 new members among London wage-earners; its membership at the beginning of February had risen to 400,000, and its income is now about £275,000 annually. This sum, obtained by voluntary contributions of 3d. a week, is distributed, on a pre-arranged scale, to co-operating hospitals.

A REVISED edition of the *Pharmacopoeia of the Paddington Green Children's Hospital* has now been issued.

MESSRS. J. AND A. CHURCHILL announce for early publication *Oils, Fats, and Fatty Foods*, by E. Richards Bolton, being the second edition of the book by Bolton and Revis, with a chapter on "Vitamins" by Professor J. C. Drummond; also a new edition of *Recent Advances in Biochemistry* by John Fryde, M.Sc., and a volume entitled *Laboratory Manual for the Detection of Poisons and Powerful Drugs* by Dr. W. Autenrieth, translated from the fifth German edition.

THE Institute of American Meat Packers has recently published a recipe book describing forty ways of serving liver. Medical practitioners who desire a copy of this booklet should apply to Messrs. Armon and Co., Ltd., Queen's House, Kingsway, W.C.2.

THE Astor challenge shield, which is awarded by the National Baby Week Council, was won in 1927 by the Northampton Maternity and Infant Welfare Voluntary Association for the third year in succession; the Leicester Health and Baby Week Committee was second. The William Harvey challenge shield, reserved for smaller areas, was awarded to the Cambridgeshire Federation of Women's Institutes, which was responsible for a campaign in the villages of that county.

DR. GUSTAV GIEMSA, director of the chemical section of the Hamburg Institute for Tropical Diseases and the inventor of a well known stain, has recently celebrated his 60th birthday.

THE title of professor without chair has been conferred on Drs. Aron, Bellocq, Fontès, Gély, and Schwartz, lecturers at the Strasbourg faculty of medicine.

DURING 1927 more cases of meningococcus meningitis were reported in the United States than during the previous two years.

A MEMORIAL plaque was recently unveiled in the Medical Clinic of Münster in honour of F. W. A. Sertürner, the discoverer of morphine, who was born at Neuhaus, near Paderborn, in 1783.

DR. BROCC, the well known dermatologist of Paris, has been made a commander, and Dr. Abadie of Oran an officer, of the Legion of Honour.

THE Innsbruck University Calendar for the current year contains an account of the various faculties and other information likely to be useful to students. An unusual feature is the insertion of illustrations, including some of the professors at work, the celebration of the 250th anniversary of the foundation of the university, and views of the surrounding country, particularly Tyrol.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9561, 9562, 9563**, and **9564** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

## QUERIES AND ANSWERS.

### UNUSUAL PIGMENTATION OF SCALP.

DR. D. I. WALKER (Bauß) reports the case of a boy, aged 9, who has a patch of jet black hair on the right parietal and frontal region of the scalp, the hair otherwise being of a sandy fair colour. The patch is . . . 6 inches by 1½ inches, and is horseshoe-shaped, the upper edge being . . . the lower border is irregular. It stretches from the middle line of the skull posteriorly to within an inch of the edge of the hairy part in front. There are no pigmentation or changes in the colour of the hair such as follow an injury, skin diseases, or special treatment, and the patch has been present from infancy. It suggests the coloured areas found in lower animals.

\* In regard to this case Dr. H. Haldin-Davis writes: This is an extraordinarily rare anomaly of scalp pigmentation. It is not particularly uncommon to find a patch of leucoderma in the scalp, from which the hair grows white with quite a becoming effect. Many will remember the late Maurice Parkes, in his day a well known actor, who possessed this peculiarity. But a parti-coloured coiffure is a much rarer phenomenon. I have seen a man whose occipital hair is several shades lighter than that over the crown of his head, but the only case I am aware of at all similar to that reported by Dr. Walker is one published by M. Wunsch in the *Berl. Klin. Woch.* in 1910 (vol. xlvii, p. 832)—a boy with black hair, but with a number of patches of red hair mixed with it. The skin under the red hair was pink, while that under the black was white. The outlines of the patches were quite sharply defined, and the general effect must have been very odd.

### DRY MOUTH.

DR. W. JOHNSON SMYTH (Bournemouth) writes: If "B." (*JOURNAL*, February 4th, p. 204), who is concerned with a patient with "dry mouth," will try the mountain ash (rowan tree) berries I think he will relieve the symptom. I noted their efficacy in the **BRITISH MEDICAL JOURNAL** a few years ago. Messrs. Martindale, chemists, Cavendish Street, London, W., keep them in stock, I think. If not, I will gladly send some preserved berries to "B." if he sends his address.

### FREQUENCY OF MICTURITION.

DR. W. NUNAN (Bombay), replying to Dr. J. McWhirter's inquiry (*JOURNAL*, December 24th, 1927, p. 1214), recommends suggestion treatment when other methods have failed to give relief. He has known it to be of great value in cases of "bladder irritability."

### CLEANING DENTURES.

"J. R. R. H." writes: In further reply to "T. M." (*JOURNAL*, January 28th, p. 164) I find that carbonization can be prevented by the following method. Take a pencil-shaped piece of wood with a blunt point and a little dentifice on the plate; wet the plate and scrub the surface with the point of the pencil. If this is done once a week, or when the vulcanite begins to get blackened, the discoloration can be rubbed off. It requires about ten minutes, and patience. A hard brush and dentifice will also keep the pink gum clean. I do not think the method would be effective in the case of a thick deposit of carbon.

# The Hunterian Oration ON THE PROGRESS OF SURGERY FROM HUNTER'S DAY TO OURS.

DELIVERED BEFORE THE ROYAL COLLEGE OF SURGEONS  
OF ENGLAND ON FEBRUARY 14TH, 1928,

BY

SIR HOLBURT WARING, M.S., F.R.C.S.,  
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

TO-DAY, Mr. President and Gentlemen, we celebrate the two hundredth anniversary of the birth of John Hunter, the founder of modern scientific surgery, the creator of our Museum, and the patron saint of our College. Since 1814 an oration—the Hunterian Oration—has been given, at first annually and then, after 1855, biennially, in this College in his memory. A large proportion of these orations have dealt with one or more of the numerous branches of Hunter's activities; in fact, it has always seemed to me that there is scarcely any part of the work of Hunter which has not been commemorated in one way or another at one of these orations.

On examining the conditions as given in the trust deed which created this oration it is stated that "the Oration is to be delivered in the theatre of this College on the 14th February, and such Oration is to be expressive of the merits in Comparative Anatomy, Physiology, and Surgery, not only of John Hunter, but also of such persons who have become deceased, whose labours have contributed to the improvement and extension of surgical knowledge."

The provisions of the trust creating this oration being so wide I have thought it advisable on this occasion—the bicentenary of the birth of John Hunter—to devote the time allotted to me for the purpose in giving a short review of the progress of surgery since Hunter's day to ours, in the course of which I propose to make reference to a few of the most distinguished scientific investigators, the results of whose work have proved to be of the greatest value to the science and practice of surgery.

Hunter has been regarded, quite rightly, both in this country and to a lesser extent in foreign countries, as the practical founder of modern scientific surgery. After his earliest surgical days (1760–70) he formulated the idea that it was absolutely essential for a practising surgeon—who wished to practise his art with the greatest prospect of success and benefit to his patients—to have a very close and detailed knowledge of the structure and functions of man in health; that he should also be familiar with, again in every detail, the changes which take place in man during the onset, course, and development of any disease which he is called upon to treat; and furthermore that he should also have a comprehensive and detailed knowledge of the vital processes which take place in the tissues of the patient during the period of recovery from disease and after the performance of a surgical operation. From these facts it will be seen that Hunter fully realized that a minute and thoroughly comprehensive knowledge of the pathological processes occurring in inflammation and growth is the real basis of a considerable amount of practical surgery. This holds to the present day.

The method of investigation which Hunter appears to have carried out when examining any subject was the following. He first made himself master of the details and minute structures of an organ or tissue, and then investigated its functions. In making these investigations he did not hesitate to compare the structures and functions of animals with those of man. Having made this extended structural and functional examination he reflected upon and reviewed the whole, and then came to conclusions. After he had done this, he then in a similar way investigated the structure and functions of organs and parts of living bodies in connexion with the onset, course, and result of disease. This consideration of structure and function in normal conditions, followed by a consideration of the structure and function in similar diseased conditions, is really the basis upon which Hunter commenced to make

surgery a real science. He for one thoroughly understood that in order fully to comprehend the nature of a disease of an organ it is absolutely essential to be familiar with the structure and functions of such an organ under healthy conditions.

In connexion with the ideas which were formulated by Hunter concerning the practice of surgery it is very interesting to read his physiological works and his speculations on the "basis of life." The condition of physiology in Hunter's student days was very little advanced. Hunter himself appears to have derived a considerable portion of his knowledge of physiological processes occurring in man from his direct observation of similar processes occurring in animals and even in plants, in addition to the modifications which he observed in man during the treatment of his patients.

Hunter, like every true physiologist, instead of trying to theorize as to what was the exact chemical or physical basis of life, investigated all the signs and conditions under which life shows itself, and also dissected where possible, or examined in minute detail, all structures which showed signs of life. By these means he was able to formulate within his own mind what he himself understood by life, or "the vital principle," or whatever the condition may be called. Hunter believed that "life existed in every part of the animal body," and this life, or "vital principle" as he called it, made every part of the animal body susceptible to the impressions which excite action.

Since Hunter's day every advance in our knowledge of chemistry and physics has been used in attempting to explain the onset and course of disease, and the actual biochemical and biophysical processes which occur in living matter or matter endowed with the characteristics of life. So far, however, these researches have given us more enlightened ideas of the chemical and physical conditions under which "life" may exist and may be destroyed, but no ultimate chemical or physical explanation has been discovered of the true or real chemical or physical basis of life.

## IMMUNITY AND PREVENTION OF DISEASE.

The first subject which I wish to discuss as being of supreme importance in the progress of surgery is what is now called immunity and prevention of disease.

During the period of Hunter's life (1728–1793) little or nothing was suspected or known of what we now describe as immunity. Edward Jenner (1749–1823), an intimate friend and pupil of Hunter, was the first medical practitioner in this country to appreciate the great value of inoculation against disease. He noticed in his practice that milkmaids who had contracted cow-pox from the udders of cattle when milking did not take small-pox. According to Baron, in his *Life of Dr. Jenner*, the first inoculation was performed by Jenner upon a country boy aged 8½ years (named James Phipps), in May, 1796. He inoculated the boy with the matter obtained from vesicles upon the skin of a milkmaid suffering from cow-pox. Almost two years later, in a similar manner, he inoculated his own son along with several other children. As a result of these investigations inoculation of children with the exudation from the vesicles of persons suffering from cow-pox was used as a protection against the possible subsequent development of small-pox.

As we all now know, laity and otherwise, the ravages of small-pox have practically been set aside in this country by the systematic practice of vaccination. It is very rare nowadays in England to meet with anyone who has features disfigured with pits, the result of previous small-pox.

## BIOCHEMISTRY.

The discoveries in biochemistry, such as those of von Behring (1854–1917), Koch (1843–1910), Ehrlich (1854–1915), and Wassermann (1866–1925), have given us very valuable means both of diagnosis and treatment.

*Diphtheria Antitoxin.*—Von Behring, in 1890, discovered the antitoxin of diphtheria, and found that by injecting this antitoxin into patients affected with the disease diphtheria could be controlled and rendered practically innocuous. Up to that time a considerable proportion of patients suffering from diphtheria died from one condition or another, a large number of them having to be

submitted to tracheotomy on account of laryngeal obstruction due to diphtheritic membrane. In England, at the present day, owing to the general use of von Behring's diphtheria antitoxin, it is extremely rare to see a patient suffering from diphtheria in whom tracheotomy is necessary. At St. Bartholomew's Hospital, in my student days, tracheotomy for tracheal obstruction due to diphtheria was a very common operation. Nowadays it is practically never seen. In 1890 the number of patients treated in this way was 47, and in 1927 there was none.

**Antitetanic Serum.**—Antitetanic serum, which was discovered by von Behring and Kitasato in 1892, was used extensively in the prevention and treatment of tetanus during the great war. The soil of the low-lying lands of Flanders is said to be almost always infected with the bacillus of tetanus (discovered by Nicolaier in 1884); hence gunshot wounds sustained by soldiers in this area were prone to become infected with the organism, which caused an attack of tetanus. It has been stated that the death rate among inoculated soldiers suffering from tetanus during the great war was 23 per cent. as compared with 53.5 per cent. in those who had not received preventive treatment.

Other diseases which have been treated successfully, either by prevention or cure, in a similar biochemical manner, are hydrophobia, typhoid, and anthrax.

Many attempts have been made to render patients immune from streptococcus infection by the injection of vaccines, etc. At the present time, however, it does not appear that any certain remedial measure, biochemical or otherwise, apart from surgical asepsis, has been found which can be relied upon for absolutely preventing the occasional occurrence of a streptococcal or staphylococcal infection after an operation. Some success has been claimed for the use of an antistreptococcal serum in connexion with possible infection by the streptococcus, but the exact value of this is not clear at present. Certainly, in my experience, there is no streptococcal antitoxin or serum which can be injected into a patient and be absolutely relied upon to prevent or cure infection with virulent pathogenic streptococci.

**Insulin.**—The biochemical researches of Banting and Best of Toronto in 1921 and subsequently led to their discovery in, and isolation from, the pancreas of a substance which was named "insulin." The administration of this substance so improved the metabolism of carbohydrate material by diabetic patients that in many cases operations which previously had been thought inadvisable and dangerous have been rendered possible, and the lives of a large number of patients very considerably prolonged. Best has recently stated that, in his opinion, the lives of about 200,000 diabetic patients have been temporarily saved by the use of insulin.

#### GENERAL ANAESTHESIA.

Another most important epoch in the progress of surgery was the discovery of general and local anaesthesia. Although a certain amount of anaesthesia—usually induced by inhalation or taking internally of narcotic substances such as mandragora, hyoscyamus, certain types of hemp, opium, etc.—had been practised during surgical operations in early days, in Hunter's time this method of alleviation or diminution of pain seems to have been practically entirely forgotten, and to have gone out of use.

As I have already said, every discovery of importance in chemistry and physics which has been made since Hunter's day can truthfully be said to have been utilized sooner or later by application to surgical diagnosis and treatment. Thus the discovery of hydrogen in 1766 by Cavendish, of nitrogen in 1772 by Rutherford, and of oxygen and nitrous oxide gas in 1774 by Priestley, were the real beginnings of the application of chemical substances for the production of anaesthesia in surgical operations. Nitrous oxide gas appears to have been made use of first as an anaesthetic for the diminution of pain in the extraction of teeth. It is stated that Humphry Davy, about 1800, had used this gas for the alleviation of pain due to a diseased tooth. He afterwards stated, as a result of this experience, that "nitrous oxide seems capable of destroying pain. It may be used in surgical operations where there is no great effusion of blood." Unfortunately

this suggestion of Davy's was not made use of by surgeons, and it was not until almost fifty years later that the value and use of nitrous oxide gas for the induction of anaesthesia were appreciated and understood.

Faraday, another chemist, seems to have been one of the first to recognize the anaesthetic properties of ether. In 1818 he pointed out that "when the vapour of ether is mixed with common air and inhaled the effects are similar to those caused by the inhalation of nitrous oxide."

From this period onwards a number of observers made use of the inhalation of gases to diminish pain during surgical procedures. Henry Hill Hickman—a young man who became a member of this College in 1820, and practised in Ludlow, Shropshire, from 1820 to 1828—made experiments, in the autumn of 1820, on the possible anaesthetization of animals, at first with carbonic acid and then with nitrous oxide. His proposals concerning the use of nitrous oxide gas for the production of anaesthesia and its utilization in connexion with surgery were received very sceptically and generally condemned by the surgical profession in this country. So much so that he communicated with the King of France asking that an inquiry be made by the physicians and surgeons of that country as regards the value and correctness of his experiments. This communication was sent to the Académie Royale de Médecine de Paris, which body appointed a committee to investigate the matter. Nothing, however, came of this, although Hickman requested that he might be allowed to demonstrate the result of his experiments to the Paris Academy. Unfortunately, this young and enterprising surgeon died from tuberculosis the following year at the age of 29.

Crawford Long, a medical practitioner in Georgia, appears to have been the first American surgeon to make use of ether in the production of anaesthesia during the performance of a surgical operation. On March 30th, 1842, he gave ether to a patient for the removal of a tumour from the neck. This case being so successful, Long continued to make use of ether for surgical operations, and performed eight such operations between 1842 and 1845. Long, although he made no secret of his discovery, did not publish the fact to the world, and it was not until others had made a similar discovery that his experience became generally known. Two years later, in 1844, Wells, a dentist in Hartford, Conn., made use of anaesthesia by nitrous oxide for the extraction of teeth. Although Wells had attempted to produce anaesthesia with ether, he had not been able to continue to do so, owing to the difficulties and choking sensations which were produced. Morton, however, who had been a pupil of Wells, was familiar with the properties of ether, and independently discovered its anaesthetic qualities four years after the discovery by Long. Apparently the first public exhibition of surgery without pain was given in Massachusetts General Hospital in October, 1846, when a patient was operated upon by Warren for removal of a vascular tumour of the neck, after being anaesthetized with sulphuric ether.

Ether was first used in England for the induction of general anaesthesia during the performance of an operation (removal of a tooth) in December, 1846, and two days later ether was administered to patients at University College Hospital by Squire for Liston, who amputated the lower extremity through the thigh in one patient, and also in another removed an ingrowing toenail.

During the following year (1847) Simpson of Edinburgh used ether in obstetric practice, and found that the pains of labour could be abolished thereby, whilst the uterine contractions were not interfered with. The next year (1848) Simpson, who was somewhat dissatisfied with the use of ether on account of the irritation which it produced in the lungs and bronchial passages, first made use of chloroform. This substance was discovered at about the same time by two investigators—by Soubeiran in 1831, and by Liebig in 1832; its composition was first accurately described by Dumas in 1835.

Since this period (1847-48) ether, chloroform, nitrous oxide, in many and various combinations, and other substances have been used for the induction of surgical anaesthesia. Recently a most important combination which has been made use of is that of nitrous oxide, oxygen, and a

small amount of ether or chloroform. This combination is especially useful and safe when administered by the intratracheal method.

#### LOCAL ANAESTHESIA.

**Cocaine.**—Cocaine as an alkaloid was first isolated, apparently by Godeke, about 1855, and some points as regards its power of producing local anaesthesia were noticed. No definite advances were made, however, until 1874, when Bennett showed that cocaine, applied to living tissues, had the power of causing local anaesthesia. V. Anrep, however, in 1878, appears to have been the first to investigate completely the anaesthetic properties of cocaine by injecting a dilute solution (0.003 to 0.5 per cent.) underneath the skin, and in connexion with this made the suggestion of its possible value for producing anaesthesia for surgical operations. In the following year (1879) its powers of producing local anaesthesia were demonstrated in connexion with the eye. This use of cocaine was worked out in complete detail by Karl Koller, who showed that complete anaesthesia of the eye could be produced by the use of a 2 per cent. solution. The results of Koller's experiments were first published and discussed at an ophthalmological congress in Heidelberg in 1884. Since then this drug has been used increasingly for the production of anaesthesia in all kinds of surgical operations. Some difficulties were met with at first in connexion with poisoning by absorption, but these were soon overcome.

**Novocain.**—Considerable progress in the method of induction of local anaesthesia has been made since that date by the discovery of novocain, a synthetic product derived from coal-tar (para-amido-benzoyl-diethyl-amino-ethanol hydrochloride) by Alfred Einhorn in 1905. So much so that at the present time a considerable number of major surgical operations, such as removal of tumours of the thyroid, gastrectomy, radical operation for hernia, etc., and even almost any major and minor operation, can be done painlessly, and in certain cases with greater safety to the patient, by the use of a dilute solution of novocain, administered by the infiltration method.

**Stovaine.**—Another variety of anaesthesia, or analgesia—spinal—can be induced by the injection of a solution of stovaine into the lower portion of the spinal theca. This form of anaesthesia is especially used in operations on the portion of the body below the diaphragm, such as prostatectomy, hysterectomy, etc., when there are contraindications, such as affections of the lungs, etc., to the administration of a general anaesthetic.

The net result of all these discoveries and improvements in connexion with surgical anaesthesia—general and local—is such that almost any desirable and justifiable operation can now be performed by the dexterous surgeon, well trained in anatomy and technique, painlessly and with very slight anaesthetic risk to the patient, when the administration of the anaesthetic is carried out by a well trained anaesthetist.

#### PATHOLOGY AND MICROSCOPICAL DIAGNOSIS.

The publication of Virchow's (1821-1902) work on cellular pathology in 1858 was a great incentive to surgeons to study the histological basis of a considerable number of surgical diseases, especially all forms of new growth. From this period (1858) to the present time there has

been a continuous advance in our knowledge of the pathology of surgical affections, one of the latest, perhaps, being the recognition of the different histological characteristics of malignant growths. This has enabled surgeons to be in a much better position as regards giving a correct prognosis after an operation for malignant disease. These advances have been made possible by the improved construction of the microscope and the knowledge of the reactions of human and other tissues to different varieties of dyes and stains.

The improvements which have been made in the microscope since Hunter's day have been very considerable. In Hunter's time the microscope was an instrument which was little more than a simple magnifying lens.

The principles of the compound microscope were discovered and developed by many physical observers, one of whom was Joseph Jackson Lister, the father of Lord Lister, in 1830. The discovery of the principle of the homogenous immersion lens, followed by great improvements in the construction of lenses which were called apochromatic, have made possible a large number of researches in histology and bacteriology. As examples of the microscope in use in Hunter's day and of that now in use I have had placed on the table two—one a microscope of 1760, and as used by Hunter, and the other a modern one. I also show you the microscopes used by Pasteur and Lister.

The first surgeon to utilize reflected light in the investigation of deep spaces or cavities of the body was Bozzini of Frankfurt-am-Main, who invented, in 1805, a form of urethroscope and also other forms of "scopes." Each consisted of a hollow tube along which light was reflected by a mirror. No practical results, however, emanated from this discovery at the time, and its use remained quiescent apparently for a considerable period. The next observer to make use of reflected light in the examination of patients was Helmholtz, who invented the

ophthalmoscope in 1851. His original ophthalmoscope was, as regards its success in working, dependent upon the reflection and concentration of a source of light, usually a candle or a lamp. By its use ophthalmology became established on a scientific basis. Soon afterwards, in 1855, Manuel Garcia invented the laryngoscope, which was used by Torek of Vienna; then followed the rhinoscope, discovered by Johann Czermak in 1859. Nitze and Leiter made the most rapid advances in the utilization of reflected light for interior investigation of the body by combining the principles of the telescope and reflected light, and the production of the cystoscope in 1877.

The value of these instruments for investigation of the recesses and cavities of the body was enormously increased by the invention of incandescent light. Paul Jabluchkov, in 1876, invented the electric candle; Swan and Starne of England and Edison of America improved upon this invention and produced incandescent electric lighting in 1880. David Newman of Glasgow improved the cystoscope as designed by Nitze and Leiter, and in 1883 was the first to make use of incandescent light in connexion with it. With this instrument (Fig. 1) it became easily possible for the practised manipulator to investigate and diagnose the various conditions affecting the urinary bladder. The laryngoscope was also further developed and improved, and the diagnosis of surgical affections of the interior

FIG. 1.—Cystoscope with electric lighting as used by David Newman. (a) In position for introduction. C, Speculum of hollow vulcanite the apex of which, J, is movable by handle L. (b) In position after it has been introduced into the bladder. K, Speculum, the apex of which, J, has been moved by the handle L so as to enable the observer to see through the glass disc which closes the end within the bladder. (c) Electric lamp and handle which is introduced passed along the speculum after introduction.

of the larynx was made possible in their early stages. Other forms of "scopes" for the investigation of the interior of the body which rapidly followed the earlier discoveries were the sigmoidoscope by Badenhauer in 1863, afterwards perfected by Kelly of Baltimore and Strauss of Berlin; the oesophagoscope by Kussmann in 1869, as well as the first gastroscope during the same year (later perfected by Mikulicz in 1881); and the bronchoscope by Gustav Killian in 1898.

The latest application of the combination of the telescope and electric light for clinical and diagnostic purposes is the thoracoscope. A similar but much larger instrument is used for investigation of the interior of the stomach. The practical value of the gastroscope, however, in diagnosis is somewhat problematical, owing to the difficulty of correctly interpreting the conditions seen through it, and the fact that it cannot be used readily and with advantage when a patient has been anaesthetized.

One example of the application of improved mechanical methods to surgery was the invention of the lithotrite and vesical evacuator by Bigelow in 1878. With this instrument patients were successfully treated and cured of stone in the urinary bladder without any cutting operation. Since Bigelow's day the instrument has been considerably improved in detail, including the addition of an electric light attachment, though the essentials are absolutely the same. Expert operators can obtain excellent results by this method. In hot and tropical countries such as Egypt and India, where stone is prevalent and the natives are not readily amenable to the discipline, aseptic and otherwise, necessary for a successful surgical operation, this method in the hands of the skilled operator has enormous advantages.

#### ANTISEPSIS AND ASEPSIS.

The next avenue of progress in surgery is that branch of biology and biochemistry which we call bacteriology. Hunter, of course, was ignorant of bacteriology, since bacteria had not been discovered in his day. It is of interest to note that in his surgical lectures given in 1785 he states, in connexion with fermentation: "Fermentation appears to be a process peculiar to dead vegetable or animal matter, and when we find a tendency to fermentation we may conclude that there is a defect of the living principle." The modern science of bacteriology and its possible application to surgery really commenced in 1857, when Pasteur published his paper on lactic fermentation, and subsequently his paper on the influence of oxygen on the development of yeast and on alcoholic fermentation, in 1861.

The adoption by Lister of his antiseptic doctrine in connexion with surgery in 1867, which really followed the work of Pasteur, was the commencement of what may be known as advanced surgery on a scientific basis. The general acceptance of Lister's doctrine and its application to practical surgery was slow in this country. However, in the late eighties and early nineties its practice became general, and was quickly followed by the aseptic doctrine. The practice of modern surgery is really based on a combination of antiseptics and asepsis, principally the latter. All the points, however, on the subject of Lister were discussed by last year's Hunterian orator. It is sufficient

far me to say that the practice of asepsis and antisepsis in surgical operations has enabled surgeons to submit to operation with success every organ and almost every part of the human body. The surgery of the abdomen was first perfected, especially by von Billroth of Vienna, in connexion with gastro-intestinal operations, and by Spencer Wells and Lawson Tait as regards operations upon the ovaries, uterine, and Fallopian tubes; then that of the brain and cranial contents, and more lately that of the thorax and its contents.

The net result of the practice of asepsis in operations is that infection of and suppuration in operation wounds is almost non-existent in most modern hospitals, and the mortality from surgical operation has been very greatly reduced.

#### TRANSFUSION OF BLOOD AND ITS APPLICATION TO SURGERY.

Transfusion of blood, either directly from one individual to another or indirectly, was first practised, apparently, on animals by Lower in 1665, and on man by Denys of Paris in 1667. No definite progress was made, however, in the

application of this procedure to surgery until the latter part of the nineteenth and the beginning of the twentieth century.

Eisenberg, in 1901, discovered that the blood serum of both diseased and normal individuals, when injected into another individual of the same race, was liable to haemolysis the blood of the receptor. After this discovery Jansky, in 1907, divided the blood of human beings into four groups, and in 1910 Moss repeated this investigation and graded individuals according to the character of their blood into four groups.

Further, the advances made possible by our knowledge of biochemistry and bacteriology have enabled the indirect method of transfusion of blood to be very much perfected. So much so that at the present time it is quite an easy matter for a person who has mastered the technique to obtain blood from a suitable selected donor, keep it sterile and uncoagulated by the sodium citrate method, and to inject it immediately into the blood vessels of the recipient. These procedures are now in quite constant use in hospitals and surgical practice in certain types of serious injury or disease, especially when a large amount of blood has been lost by the patient, and have proved of great advantage in enabling operations to be done, and the lives of patients saved thereby which otherwise would have been lost.

#### RADIOLOGY.

Another "milestone" in the progress of surgery between Hunter's day and ours is marked by the successive discoveries of x rays and radium.

The discovery of x rays by Wilhelm Roentgen (1845-1923), professor at Würzburg, in 1895 was the commencement of a series of great advances in surgical diagnosis. At first the use of x rays in this direction was mainly confined to injuries to and diseases of the bones. When, however, the possibilities of this discovery were more appreciated and understood it was found possible to extend the clinical use of x rays in diagnosis to other conditions. Thus, as regards the internal organs and viscera, especially portions of the

FIG. 2.—Amputations as performed in the days of Hunter.

FIG. 3.—Amputation at shoulder-joint, as performed in 1820 after introduction of the straight amputation knife.

alimentary canal, the existence of diseased conditions was readily demonstrated by the taking of a skiagram of the diseased, or presumed diseased, region and organ, after the administration by the mouth or the rectum of barium sulphate or bismuth nitrate. Thus the diagnosis of ulcers and neoplastic growths of the stomach and duodenum, narrowings in different portions of the alimentary canal, such as occur in carcinoma of the oesophagus, or carcinoma of different portions of the alimentary canal, especially the lower portion of the large intestine above the rectum, was made possible. The determination of the position of deep-seated fistulous conditions between the viscera has also been made possible.

The value of x rays in connexion with the diagnosis and treatment of disease has in many cases, and especially by the laity, been much exaggerated. To the practising clinician x rays, when intelligently and scientifically used, can, as we all know, be of enormous advantage. They are of great value in the detection and localization of different forms of calculi, especially those in the ureters and kidney. One of the later developments of the use of x rays in diagnosis is the investigation of the ureters and pelvis of the kidney by what are known as "ureterography" and "pyelography." By these means of investigation many obscure cases of disease in the kidneys and ureters have been diagnosed satisfactorily, and subsequently operated upon with great prospects of cure.

Calculi in the gall bladder for a long time evaded the attempts of the x-ray practitioners definitely to detect them. Occasionally when suspected they could be demonstrated on an x-ray plate or film, but often no evidence was apparent, although the clinical signs and symptoms pointed to their presence, and at operation they were found. Improved x-ray machinery and the intravenous injection of tetraiodophenolphthalein or tetrabromophenolphthalein, and its excretion by the liver, at the present time, however, usually enable definite evidence to be found of the presence of cholecystitis and calculi in these cases. As everyone knows, a patient is much more ready to submit to an operation for removal of a calculus in the ureters, kidneys, urinary bladder, or gall bladder if its presence can be shown on an x-ray film or plate than if it is only assumed. In a similar manner x rays have been of use in detecting the presence of stone in the pancreatic duct or deep-seated calculi in the submaxillary salivary gland.

During the recent great war x-ray diagnosis was increasingly made use of in the detection and localization of injuries to bones and the presence of bullets and other metallic substances which had entered the bodies of wounded soldiers.

Following the discovery of x rays by Roentgen, Monsieur and Madame Curie, in 1898, discovered radium in pitch-

blende derived from mines in Joachimstal in Bohemia (now Czechoslovakia). The salts of this metal were found to possess very marked radio-active qualities, and have been used, especially of recent years, in the treatment of various diseases, and particularly in forms of new growth. There is no doubt that certain types of sarcoma and carcinoma are very sensitive to the action of radium, and a number of patients have apparently been cured by the use of the salts of

this metal. Radium has been applied in various ways, but in the treatment of disease the best results have been obtained by the implantation of either radium needles or radium seeds in the margins of diseased tissues. As in the case of x rays, the exact value of radium in the treatment of malignant disease cannot yet be determined. Unfortunately, a large supply of radium is very expensive and difficult to obtain. The indications, however, appear to be that if an increased quantity of radium or its salts can be obtained and made available for clinical use, then considerably improved results in the treatment of malignant disease may be made possible.

FIG. 4.—Operation as performed in the early days of "Listerian" practice. The patient has been anaesthetized and the carbolic spray is being used.

#### CRANIAL AND SPINAL SURGERY.

In connexion with the surgery of the cranium and its contents Broca's investigations into the localization of function, and especially his localization of the centre of articulate speech in the left frontal convolution, enabled him to perform the first fixed operation for cerebral abscess, which was assisted by localization of function in connexion with "motor aphasia," in 1861; since then numerous researches into the localization of cerebral functions have enabled neurologists and neuro-pathologists to determine

the site of a large number of intracranial growths.

Quite a considerable proportion of the advances in cerebral and spinal surgery has been due to two Fellows of this College—Victor Horsley (1857-1916) and William MacEwen (1848-1924), now deceased.

Recently much assistance has been obtained in the exact localization of a tumour within the spinal canal by the injection of lipiodol into the spinal canal and subsequent examination with x rays. The lipiodol shows as an opaque shadow on an x-ray plate; consequently any narrowing or encroachment upon the intraspinal space by a tumour becomes evident. Similarly injection of lipiodol into the trachea, bronchi, and lungs has enabled the clinician, on subsequent examination by x rays, to demonstrate positively on plate or film the extent and nature of abnormal intrathoracic conditions.

#### SPECIALIZATION IN SURGERY.

The numerous methods—chemical and physical—available to the clinician and the pathologist for the investigation of patients suffering from surgical affections are so varied that at the present time it is not usually possible for one

FIG. 5.—An operation being performed at the present day.

A further improvement in war surgery was the recognition of the fact that in many cases of suppurating wounds, or badly lacerated limbs in which an amputation had to be performed, the wounds could be left open and treated by the Carrel-Dakin irrigation method. Free exudation and associated irrigation enabled the wounded surface to become clean, and delayed suture of the wound could be carried out afterwards. As a result of the treatment of war wounds on improved biochemical and biophysical principles the mortality from gunshot wounds and injuries was enormously decreased.

## CONCLUSION.

From the short account which I have been able to give you of the progress of surgery from Hunter's day to ours, it will be seen that the actual technique employed in the performance of surgical operations, and the results which can be obtained thereby, have reached a very high stage of perfection. It does not appear to me that we can expect in the future such great progress to be made in the details of the performance of operations themselves, and the amelioration of the discomforts directly resulting therefrom. In my opinion the main direction of advance of surgery in the future will be along biochemical and biophysical lines, both as regards diagnosis and treatment. If this assumption be correct, it is essential that the medical student and the medical practitioner of the future should pay increased attention to all biochemical and biophysical problems, both in normal and in diseased conditions.

Owing to the length of the curriculum and the multiplicity of subjects which the student of medicine of the present day has to pass through, there is a tendency for parts of the curriculum to be forgotten after the examination in it has been passed. Consequently the application of physiology in the investigation of disease is too often neglected, and a student thereby is encouraged to acquire surgical knowledge—especially diagnosis—in a somewhat empirical manner. At the present time, however, there is a tendency in every modern school of medicine to give courses of "applied physiology and applied anatomy" during the later and clinical part of a student's career.

## THEORIES OF SUGGESTION.\*

BY

WILLIAM BROWN, M.A., M.D.Oxon., D.Sc.,  
M.R.C.P.LOND.,

WILDE READER IN MENTAL PHILOSOPHY IN THE UNIVERSITY OF  
OXFORD; HONORARY CONSULTING PSYCHOLOGIST, BETHLEM  
ROYAL HOSPITAL; PSYCHOTHERAPIST, KING'S COLLEGE  
HOSPITAL, LONDON.

## I.

THE word "suggestion" has been used in educational, scientific, and medical literature in slightly different senses. In the writings of educationists and purely scientific psychologists it has been used to indicate a general kind of influence brought to bear on the mind, an influence which is other than that of logical or rational argument. The mind can be influenced rationally and also irrationally. Rationally, it is influenced, for example, when a child is taught the fifth proposition of Euclid, in learning to understand the steps one by one in the right sequence and in the right connexion; but the child can be influenced non-rationally, in its learning of this and other school subjects, by virtue of its general mental attitude towards the teacher, by the views on life of its fellow students, even by the beauty or ugliness of the rooms and buildings in which it is taught, by the climate, by the fact of the weather being fine or dull, and in a hundred other ways. These are non-rational, although not necessarily irrational, influences. They may not be contrary to reason, but they are independent of reason so far as the child individually is concerned. We may regard this class of non-rational influence as influence by suggestion.

Again, the child may be misled in his reasoning process and may fall into error. Many of the conditions under which he falls into error can be put under the same heading of suggestion. In a general educational way we may use the term suggestion in a wide sense which covers all non-rational and includes irrational modes of influencing the mind. An individual may be influenced by inanimate objects, by social conditions, or by his fellows, not only non-rationally, but also *unwittingly*—that is, without realizing that he is being influenced. The weather may be depressing, and his fundamental mood may follow suit without his being explicitly aware of the fact; the influence

there is an influence of suggestion. It may be considered a rational influence if he observes in the morning that the weather is bad, and infers from it (on the basis of previous experience) that he will have a bad day and will not be able to work so effectively as usual. But that view is not necessarily a true view; he may be mistaken in it. Even if it is a true view, so that the result is rational, it is not necessarily the work of reason.

The word suggestion in pure psychology has been used in an even wider sense. In Professor G. F. Stout's *Analytic Psychology* there is a chapter headed "Relative Suggestion," but what he is referring to there is the effect of pre-formed associations on the activity of the mind. Certain experiences have been passed through and retained in memory; and if one experience is repeated it tends to call up the memory of another. One experience "suggests" the memory of another experience. Suggestion, then, may work according to the rules of association, either of contiguity or of similarity; that is a very wide use of the term. An officer's gesture may suggest a certain movement to the platoon under his command, and they may spontaneously move accordingly without having received a definite verbal order. The response to the command may be regarded as due to suggestion. It is not necessarily rational—not a form of persuasion, which is the word to use in speaking of the process of influencing a person by rational means. Giving a command or making a request may be, but is not necessarily, a rational method of influence. In its essence a rational method, it may on some particular occasion be either rational or non-rational. It should probably be classed under the general heading of suggestion, taking the word in its widest sense.

From these uses of the term suggestion—a suggestion which involves a non-rational influencing of the mind—we pass to the more medical side of the subject. In psychological medicine the use of suggestion has developed out of the earlier use of hypnotic influence.

I must first emphasize the fact that hypnotism and suggestion are not the same thing. The state of hypnosis is a state of mental dissociation, in which certain interests of the subject's mind may be appealed to while other parts of the mind remain in abeyance. When a person is hypnotized he is more ready to respond to the influence of the hypnotist because the dissociation of his mind prevents him from being able to call upon his reserves—to bring up other considerations. The hypnotic subject receives a command or request from the hypnotist, and his impulse is to respond immediately. Considerations tending towards a different line of action simply do not occur to him; they cannot, because there is a break in the mind. He cannot review the situation and consider alternatives, and certainly does not even begin to consider them. We see that in hypnosis he has become more suggestible, and that his increased suggestibility, or increased readiness to respond to suggestion, is in part the result of mental dissociation.

But the opposite relationship may hold good. Instead of suggestibility following upon the state of hypnosis, we may find a state of hypnosis following upon suggestion. Indeed, this is what generally occurs when a person is hypnotized. The hypnotist suggests to the person that he will become more and more drowsy, more and more lethargic, but that he will continue to hear and understand what the hypnotist says to him, so that through suggestion from the hypnotist dissociation takes place. A person is robbed of the power of controlling his mind as a unitary system.

The procedure in the case of a patient requiring hypnotic treatment is as follows. After a preliminary general examination—that is, a physical examination and a psychological investigation of the conditions under which his illness had set in, which need not take very long, although a detailed psychological examination (anagnos) would require many hours—after this analysis, if the patient is considered suitable for hypnotic treatment, the physician asks him to lie down on a couch, to relax his voluntary muscles,\* to fix his gaze on a small mirror or

\* A paper read before the Section of Psychiatry, Royal Society of Medicine, on January 16th, 1928, and published by permission of the honorary editors of the Society.

The name, *pois asinorum*, given to this proposition may exert a suggestive effect upon the child, in one or other of two ways, according to his temperament—namely, discouragement, or as a challenge to a more determined attack.

\* The patient may be given detailed instruction in the matter of muscular relaxation. If he directs attention to the small distal muscles of hands and feet he will find that relaxation of these tends to spread to the larger muscles of the arms, legs, etc. Deep and regular breathing also helps relaxation.

other luminous object held about ten inches from his eyes and slightly above the horizontal plane of vision—so that he has to turn his eyes slightly upwards and inwards—to look steadily at it, to fix his visual attention on it, and to think of sleep. The hypnotist then proceeds to suggest that the patient is getting more and more drowsy—that his eyelids are getting heavy with sleep—that he will soon be asleep, but will continue to hear what the hypnotist says to him. The patient's eyes close and he appears to sleep. The hypnotist may then suddenly hold his attention by speaking more urgently and more dramatically, saying, "You may try as hard as you like, but you cannot open your eyes." The mere fact that he is challenged in this way makes him suddenly lose the knack; there arises the momentary fear, "Perhaps I shall not be able to open my eyes," and that momentary fear prevents him from opening them. He gets into a slightly emotional condition, and is ready to believe other statements made to him. If passes (with or without contact) are made down the arm and hand, with suggestions of rigidity and anaesthesia, the arm does become rigid so that the patient is unable to bend it, and it also becomes anaesthetic, so that a sterilized pin may be plunged deep into the flesh without causing any pain. In a deeper stage still the patient may become apparently quite unconscious, although subsequent investigation may show that he has retained an inactive dream-like consciousness throughout the experiment.

Hypnosis seems to proceed in stages, of deeper and deeper degree; but nowadays we do not speak of stages of hypnosis, because they have no definite order of sequence.\* We find that the order in which they occur depends to a very large extent upon the way in which, or the conditions under which, suggestions are given. The patient falls into a hypnotic state, and in that state becomes more suggestible, more ready to respond to suggestions, verbal or otherwise, from the hypnotist, and these suggestions may be used to increase the depth of the hypnosis. One stage in a good hypnotic subject is that of waxy or plastic flexibility, where the limbs, put in any position, remain in that position like the limbs of a lay figure. This stage, like those previously described, is a state of dissociation. Indeed, most, if not all, of the phenomena of hypnosis seem to be phenomena of dissociation. The simplest is the patient's inability to open his eyes; again, if he clasps his hands together and is then told by the hypnotist that he will not be able to separate them, he cannot do so. A further result of a dissociationist nature which it is very easy to produce in a hypnotic subject is amnesia. If it is suggested to the subject that he cannot recall anything that happened—for example, during the previous day—it will be found later that he is unable to answer any questions about this period of time. These are all instances of dissociation—dissociation of the power of recalling certain memories, of the power of contracting certain muscles, of experiencing certain sensations.

In a still deeper stage of hypnosis the hypnotist may seem to produce positive results instead of merely negative ones. If he suggests to a patient in a deeply hypnotized state that the latter will be able to see, say, a bright red light, the suggestion will take effect. What has happened is that the patient's imagination has been stimulated, has been set in motion, and continues working actively in a certain direction. You can take a blank card and tell him that you are going to show him your photograph, and he will see your photograph and describe it; and really, so far as can be made out, he does actually see something on the card. He projects on the card something that is merely in his own imagination. Here the difference between the hypnotized subject and the normal person is mainly a difference in the degree of activity and control of the imagination. When a person is hypnotized his imagination may become more active, but is under the control of the hypnotist; indeed, all hypnotic suggestion may be considered as an influencing of the imagination. The manifestations previously described may be regarded merely as the effect of an externally controlled imagina-

tion. An individual has been made to imagine that he cannot open his eyes; nothing having arisen to counter that imagination, it takes effect. The normal person can call up a fairly accurate picture of another individual, but to see it at a definite spot and with a certain degree of steadiness may follow upon hypnosis, where the imagination is controlled by the hypnotist. It is not that the hypnotist has any occult power (magnetic, telepathic, or what not), but that his words and gestures call out a direct and inevitable response from the patient. The patient is ready to believe and expect that what the hypnotist says will come to pass.

Various theories have been devised to account for this, and I shall discuss some of them later on. One well known theory is that of Freud—that these results follow because some bond of affection has sprung up between the hypnotized patient and the hypnotist. The patient responds to the suggestions of the hypnotist much as a young child would respond to the suggestions of a well loved parent or nurse, in primitive credulity without afterthought or other consideration. Another theory is that in the process of hypnosis the patient has been thrust into a state of self-abasement, with the result that he is ready to accept orders from another person. This is McDougall's view: that the patient is specially ready to respond to the hypnotist because, under hypnosis, his instinct of self-abasement has been aroused to the exclusion of other instincts and tendencies. In hypnotized people McDougall assumes that the instinct of self-assertion is in abeyance. Such a theory is based on the conception of dissociation—dissociation at a very fundamental level of the mind—namely, dissociation of one instinctive disposition from the others.

Dissociation may increase suggestibility, or be increased by it. A person may for the moment "forget" how to use certain mental powers, and then through fear become permanently incapacitated, or he may succumb to suggestions in other directions; or, again, he may fall into a state of dissociation, not through mental suggestion from anyone, but through some strong mental or physical shock. During the war large numbers of soldiers became readily hypnotizable under the influence of intense physical shock, either from shell concussion or from blows on the head received in other ways (falls, etc.). It is often difficult to exclude the effect of mental shock in these cases; but instances of purely physical shock, followed by dissociation, do occur. A person who gets physical concussion is almost invariably easy to hypnotize. This concussion probably brings about physical dissociation of the higher centres of the brain. The harmonious activity of the brain as a unit seems to be disturbed by such a general "shaking up." Drugs, such as alcohol, may produce a similar effect. Alcoholic persons are very easy to hypnotize, which is fortunate, because hypnotism can be used in curing them. An alcoholic person may appear to be absolutely incorrigible, but, to his surprise, he finds that he obeys suggestions under hypnosis. Anaesthetics, such as ether or chloroform, will also make a person more readily hypnotizable, and there is good reason for believing that they produce relative dissociation in the highest cerebral levels. Hypnotism was originally used for operations, and if chloroform had not been discovered shortly afterwards, no doubt hypnotism would have been used much more extensively for that purpose; it still has its uses to prepare and calm the patient's mind for an operation. It is very important that a patient, before undergoing an operation, should have his mind free from fear, should control his feelings, and not struggle against the anaesthetic. One of the best ways of bringing this about is to give him suggestion treatment beforehand, and I have done this in many cases. It has very definite effects: among others, it may save the patient from nausea after the anaesthetic. In many cases where the patients have dreaded the anaesthetic more than the operation, suggestion treatment has freed them from this fear.

It is a fact that in hypnosis the patient falls into a special state in which he responds readily to suggestions from the hypnotist, and to a great extent the characteristics of the hypnotic state seem to be explicable in terms of suggestibility. The patient becomes more suggestible to the hypnotist, and on this basis Bernheim formulated

\* The belief in a definite order of sequence of such stages was one of the errors of Charcot and the Salpêtrière school.

his definition of hypnosis as a state of artificially increased suggestibility. A hypnotized person is made more suggestible than a normal person. But such a definition is not fully adequate to the facts, because it does not explain sufficiently how the increased suggestibility is brought about. Although in some cases suggestion from the physician or hypnotist produces the hypnotic state, in other cases, as we have just seen, mental shock and physical influences—such as physical concussion, the influence of drugs, etc.—may increase suggestibility or hypnotizability, and certainly it must not be forgotten that dissociation itself increases suggestibility; that was forced upon us by the experiences of the war. Among the thousands of shell-shock patients seen just behind the lines in France and elsewhere, 15 per cent. showed functional amnesia to a greater or less extent. These patients were in a dissociated state, and in many cases had not only lost the power of recalling their frightening experiences, but had also lost the power of speaking, hearing, walking, of controlling tremors, and of bringing them to an end. There was a sort of general dislocation of the mind as well as of the nervous system. I found that these patients were easily hypnotized, and that the more pronounced the dissociation the more easily were they hypnotized. A man who had lost all his past memory could be hypnotized at once; a wave of the hand would effect this mental transformation. If the loss of memory referred to but a brief period of the past, the hypnotic state would not set in quite so readily, but every case of amnesia or dissociated memory was in some degree hypnotizable. Amnesia does not mean weakness of memory, but a loss of the power to recall a definite stretch of past experience. I observed six hundred cases of amnesia in France during the war; every case was hypnotizable, and memory invariably returned under hypnosis. Patients seen in England some months or years later were not so easy to cure; they responded less readily, but they did so eventually, nevertheless.

I am inclined to state as a general rule, admitting of no exception, that a person showing functional amnesia, without psychotic symptoms, is easily hypnotizable, and that in functional amnesia the loss of memory is easily cured by hypnosis, as well as any accompanying paralysis—mutism, etc.—of a functional nature. Facts such as these make it necessary to widen the definition of Bernheim, and to recall the earlier definition of Charcot, who used to say that hypnosis was an artificial hysteria. We need to combine the two theories (with certain omissions), and say that in the hypnotic state suggestibility is increased, but that a fundamental factor, to some extent of independent value, is a state of dissociation which works in harmony with suggestion; dissociation tends to produce increased suggestibility. The reason of this is obvious. If a person is dissociated he has no power of reviewing the situation and considering alternative modes of response. A certain mode of response is suggested to him, and he makes that response, but because of his dissociation he is unable to actuate other powers of the mind. The dissociation is not the same as increased suggestibility, for we can imagine a relatively normal person, a unified person, showing different degrees of suggestibility at different times. Moreover, although in mild forms of dissociation suggestibility seems to increase as the degree or extent of dissociation increases, this correlation does not hold for extreme cases. When the dissociation is extreme, or the state of hypnosis very deep, the patient may be found to have become less rather than more suggestible to outside influence, or even non-suggestible in certain directions.

The extremely important work of I. P. Pavlov on *Conditioned Reflexes* should be referred to here. Pavlov explains sleep and hypnosis in terms of *internal inhibition* in the cerebral cortex—spreading to the subcortical centres in the case of the former, limited to the cortex in the case of the latter.

## II.

We have now to consider in more detail the factor of *rapprochement*, which is of such central importance in the theory and practice of hypnosis.

We have already gone beyond the earlier view of hypnotic suggestion, according to which it is regarded as a form of ideomotor action, where, as Pierre Janet says,

the suggested idea produces its full or maximum effect undisturbed by conflicting ideas. This theory is not sufficient, but itself requires further explanation. An idea, to produce an effect, needs to be in relation with some source of energy. Such a source of energy is any one of the instinctive "urges" or other conative and affective tendencies. According to Freud's theory, the affective tendency concerned is of an erotic or sexual nature—not the tendency of ordinary sexual love, but a sexual tendency inhibited in its aim (*zielgehemmt*), manifesting itself in a readiness to rely completely upon the hypnotist, to be at one with him, and to grant him vigorous and whole-hearted co-operation. This is the well known factor of "transference" (*Übertragung*), so named because it is believed by Freud to be a reanimating of affective tendencies felt by the young child towards his elders in the bosom of the family. Freud quotes with approval Ferenczi's observation that there are two main and contrasted methods of hypnosis—namely, the method of command and the method of soothing and coaxing. The former corresponds to the attitude of the father towards the child, the latter to the attitude of the mother. [Compare Pavlov's purely physiological distinction of (1) monotonous stimuli of small and medium intensity repeated for a long time, producing hypnosis slowly, and (2) stimuli of considerably greater intensity, producing hypnosis quickly (in animals).]

At first sight all suggestion seems to be in essence auto-suggestion, since it must be accepted by the patient if it is to work at all; the patient has to make the suggestion his own. But there is the converse possibility that all suggestion may be hetero-suggestion—that the individual may never be able to accept anything from himself, but must always accept it from without, either from people or from the books he reads or from physical events in the outer world; so that even auto-suggestion would be hetero-suggestion. The person who applies Coué's method of auto-suggestion, and benefits thereby, owes his success to the influence that Coué has had upon him, the lectures he has heard, and the books he has read. How can this be brought into line with the Freudian doctrine of hetero-suggestion? Ernest Jones has recently attempted to solve this problem in an important article on "The nature of auto-suggestion."\* He follows Freud in maintaining that the success of hetero-suggestion is due to the re-arousal of early feelings towards the father, in which the hypnotist is put in place of the ego-ideal or super-ego, which, as distinct from the ego, is modelled upon the father. The doctrine of Freud is that in earliest years a little boy loves his father according to the narcissistic or identification type of love—he identifies himself with his father; but he loves his mother according to the dependence or "anaclitic" type, because his various physical wants are satisfied through her.† His love for his mother involves the desire to have her to himself, which arouses, by reaction, a feeling of hostility towards his father. This feeling of hostility towards his father is then repressed, by virtue of his previous identification with his father, and thus is inaugurated the contrast between the ego and the ego-ideal or super-ego. He incorporates in his own mind the character of his father as he sees him, and if he represses this hostile feeling towards his father, and develops a bad conscience about it, that bad conscience corresponds to a conflict between his ego and his ego-ideal. The child incorporates in himself the disapproval of himself which he must assume that his father would feel if his father knew. Thus the ego-ideal in his own mind corresponds with his conception of his father. When a person is hypnotized, and accepts suggestions from the hypnotist, he puts the hypnotist in the place of his ego-ideal.

In auto-suggestion, according to Ernest Jones, there is a

\* "If the primary narcissism has been released and reanimated directly, by concentration upon the idea of self, the process may be termed 'auto-suggestion'; if it has been preceded by a stage in which the ego-ideal is resolved into the earlier father-ideal, the process may be termed 'hetero-suggestion.'"—*Brit. Journ. of Med. Psychology*, 1923, vol. iii, p. 239.

† More accurately, because "in the first phase of their development the sexual instincts have no independent means of finding satisfaction; they do so by projecting themselves upon or 'leaning up against' the self-preservative instincts."—S. Freud, *Group Psychology and the Analysis of the Ego*, Eng. Trans., p. 61, International Psycho-analytical Press, London, 1922.

regression—a stepping back to a still earlier psychological situation, a situation of primary narcissism. Before the ego-ideal has been formed the child's sexual energy, his libido, is centred on himself. It is so in earliest years when he identifies himself with his father; there the libido remains fixed on himself. In the practice of auto-suggestion an individual is returning to this earliest stage and concentrating upon the idea of himself. Thus the ego-ideal is reduced to the father-ideal in the case of hetero-suggestion, and reduced still further back to the narcissistic fixation on self in auto-suggestion, which is an intensification of primary narcissism, a pronounced form of regression, and therefore bad. It means an impoverishment of the ego, the withdrawal of much energy which should be available for getting into touch with the world around and the people around, and which should enable him to live his life and make his contribution to general existence; it is a drawing of the libido back upon himself. If Ernest Jones's theory, as a further development of Freudian doctrine, is correct, it is not easy to understand the beneficial results of auto-suggestion. The improvement in physical health is not easy to explain on this theory, nor the fact that the more normal and healthy the person is, and the greater his powers of concentration, the more effective is the practice of auto-suggestion in his case. In functional illness therapeutic auto-suggestion helps to restore the patient to health, and may also greatly improve his general mental outlook on life.

Here I would urge that, as used to indicate a form of psychotherapy, auto-suggestion is an inadequate and misleading term. If we take it literally we have something which usefully indicates the pathological effects of bad auto-suggestion—the way in which a person may become ill through his imagination, or become more severely ill than he need. But the term does not satisfactorily indicate the nature of therapeutic suggestion as a correction and improvement of function. Any regression to narcissism must also mean a stepping back from the state of health and a movement towards some form of illness. It might be urged that improvement through auto-suggestion is apparent rather than real, and that actually there is an impoverishment of the mind—that what a person gains is gained at too great an expense. But we do not find that those who benefit by auto-suggestion become more self-centred; on the contrary, they become more self-confident and more free from fear of disease. Moreover, as I have argued elsewhere,<sup>1</sup> auto-suggestion in its literal form is only a stago in a process of mental development towards an adequate form of volition. Instead of being distinct from volition and a rival of volition, it is a contributory factor in complete volition. An individual who is the prey of bad auto-suggestion in a certain direction is suffering from diminished power of will in that direction. When treated by therapeutic auto-suggestion, that disability is removed. The belief and faith in himself, which is essential to complete volition, is restored to him. Belief and faith in one's self is auto-suggestion; but this is not to be identified with narcissistic fixation upon oneself. There is no reason for bringing in libido here. The instinct of self-assertion has its own form of energy, quite distinct from the libido of the sex instinct, and contrasted with it as the spirited principle (*τὸ θυραειδὲς*) is with the appetitive principle (*τὸ ἐπιθυμητικόν*) in Plato's *Republic*.

McDougall explains hetero-suggestion in terms of the instinct of submission, or of self-abasement. The patient under the dominance of this instinct surrenders his own views and accepts the views of another person. In the presence of the hypnotist his instinct of self-assertion is in abeyance, and he succumbs completely to the promptings of the instinct of self-abasement. As a theory of suggestion this view seems too limited. The operation of any instinct—powerful, profound, and independent of other instincts—will increase suggestibility and produce suggestion effects. A panic-stricken person will respond vigorously to suggestion of danger; if angry, he will readily respond to any suggestion that he is being insulted. A chance remark, of which in other circumstances he would take no notice, he interprets in a special way. Othello, under the influence of jealousy, responds to the suggestions of Iago, without any help from

"transference" or self-abasement. Not only individual instincts, but also individual sentiments\* (not to mention complexes), functioning in relative dissociation from the rest of the mind, may be responsible for pronounced suggestion effects. It is really a *tour de force* on Freud's part, and quite unnecessary, to argue that the affective tendency is ultimately always of a sexual nature, even when the word sex is used in its very widest sense and care is taken to add that the sex tendency is "inhibited in its aim." We can accept transference as a factor; we can believe that an individual may respond in an unconscious way to personal influence, after the type of his response in early childhood to his father and mother; but if a suggestion effect is response independently of reason (though not necessarily contrary to reason) this may occur through the activity of other instinctive forces besides that of the libido.

McDougall has defined suggestion as the acceptance of a statement or of an idea independently of logically adequate grounds for such acceptance. According to this definition, whenever we consciously act according to reason we are acting independently of suggestion, whereas when we act independently of reason (though not necessarily contrary to reason) we are acting according to suggestion. We know what is meant by acting according to reason. "The desire to do what is right and reasonable as such" (Henry Sidgwick) is a definite factor in our lives, and whenever we act in that way we are relatively free from suggestion. According to McDougall's definition, apart from that, all our action is under the influence of suggestion. Neither the sexual factor postulated by Freud nor the instinct of self-abasement on which McDougall himself relies exhausts the possibilities of explanation. Among other affective tendencies, of special importance in this connexion, there is the gregarious instinct, or "urge" to act in harmony with one's fellows. Freud interprets the action of this instinct in terms of the libido; he holds that the gregarious instinct explains nothing, and is itself in need of explanation. What happens in the action of the group is that there spring up libidinal relationships between members of the group towards one another, and in all of them towards the leader of the group. He proceeds to sketch out a far-fetched theory to explain how this situation arose in prehistoric times—an explanation in terms of the original family as a horde of people living together and ruled by an all-powerful father. His doctrine is that this all-powerful father of the horde is himself merely narcissistic and self-assertive; he does not need to love anyone else, his libido is fixed upon himself; but through his persecution of the sons of the family, and his suppression of them, by thwarting their sex tendency, he in some mysterious way makes them love one another and love him, and so brings about the beginnings of morality and the group spirit. For this extraordinary theory no evidence is supplied.

Freud sums up his theory of love, hypnosis, and the herd instinct in the following sentences:

"*Being in love* is based upon the simultaneous presence of directly sexual tendencies and of sexual tendencies that are inhibited in their aims, so that the object draws a part of the narcissistic-ego-libido to itself. It is a condition in which there is only room for the ego and the object."

"Hypnosis resembles being in love in being limited to these two persons, but it is based entirely upon sexual tendencies that are inhibited in their aims, and substitutes the object for the ego-ideal."

"The Group multiplies this process; it agrees with hypnosis in the nature of the instincts which hold it together, and in the replacement of the ego-ideal by the object; but to this it adds identification with other individuals, which was, perhaps, originally made possible by their having the same relation to the object."—S. Freud: *Op. cit.*, p. 125.

Without denying all truth to Freud's theory of love, hypnosis, and gregariousness, I must say that my own experience of the facts, gained through use both of the method of suggestion and also of the method of deep analysis in investigating and treating cases, does not bear out the theory in its entirety. The theory is not adequate to cover all the facts. I find similar difficulties with Ernest Jones's theory of the nature of auto-suggestion. I can quite see how regression towards the narcissistic level

\* A sentiment is an organization of instinctive-emotional dispositions centred about the idea of some object.—Shand.

may occur—how an individual may hide his head in the sand and refuse to face reality, crying peace when there is no peace; but that he would get beneficial results of a permanent nature by such a line of conduct is another matter. An appeal to narcissism might explain the state of mind of a man who stands in the corner of an asylum ward, taking no notice of anyone, but just immersed in his own fancy and in his own mental aberration; or the state of mind of the hypochondriac, with distribution of libido so disturbed that even his bodily organs cannot function adequately or without pain. But that good, or therapeutic, auto-suggestion is of this nature I cannot believe. Auto-suggestion is based on confidence and the abolition of fear. The individual who uses auto-suggestion knows this, and it is definitely admitted that auto-suggestion works better in a more healthy person; the healthier he is the better effects he can get. Auto-suggestion is a method of will training.

In holding such a view the possibility is not excluded that in hypnosis archaic affective tendencies and beliefs may come to the surface and make themselves felt, and that an individual may produce certain results by virtue of the strength of these primitive beliefs which are not justified by modern scientific knowledge, although such beliefs may make a great difference to the individual himself. In him there may be a desire for the miraculous—a desire to believe in the miraculous—which may be liberated under conditions of hypnosis, or suggestion treatment, and may produce results; not that it will produce a miracle, but it may counteract the excessive scepticism and doubt and despair which are so often characteristics of the modern mind. Consequently, bad, or pathogenic, auto-suggestion is perhaps the best example of auto-suggestion in a literal sense—that is, the working of an idea under the influence of an instinctive tendency, in this case one of fear and apprehension. Freud might say that fear is due to bad conscience, and that bad conscience is due to the working of the Oedipus complex, so bringing in the libido doctrine. Therapeutic auto-suggestion goes further, because it replaces the feeling of doubt and fear by a feeling of confidence. The result suggested can then occur, so far as it does not conflict with any of the fundamental laws of nature, and can occur to a maximum degree. The instinct of self-assertion (supported by its own distinctive form of energy, not by libido) may play a prominent part in bringing about a realization or actualization of the suggestion: but the integrated personality, with its entire reserves of instinctive energy, may, by an act of faith, fulfil more adequately the purposes towards which auto-suggestion is half blindly pointing.

## THE CAUSATION OF "STRIAE ATROPHICAE CUTIS" ("VERGETURES") NOT DUE TO STRETCHING OF THE SKIN.

BY

F. PARKES WEBER, M.A., M.D., F.R.C.P.

In all ordinary cases striae atrophicae or striae entis distensae can be explained as representing a method of cutaneous accommodation towards distension (physiological or pathological), when the skin is relatively insufficient—that is to say, unable to adjust itself by its normal elastic distensibility. In such cases a relatively too rapid growth or increase in bulk of the parts below the skin, or a cause of chronic distension of some kind—such as a relatively excessive growth of subcutaneous fat, muscle, or long bones (especially connected with puberty), mammary gland, the pregnant uterus, ascites, tumour, or subcutaneous oedema—leads to a splitting or cleavage in the deeper parts of the cutis, manifested on the surface by the appearance of striae atrophicae, which are at first red or purplish, and in time gradually become white and smaller as they heal up.

In the present note I shall refer only to those cases of striae atrophicae not due to stretching of the skin; that is

to say, the cases in which striae atrophicae have developed apparently in the absence of any special distension—in the absence of pregnancy, ascites, tumours, subcutaneous oedema, excessive subcutaneous fat, and other usual causes. In such cases the ordinary growth of the long bones, muscles, and subcutaneous fat seems to be associated with some insufficiency of the cutis (with perhaps deficiency of elasticity) which prevents the skin from adjusting itself to the parts beneath, excepting by the process of multiple cleavage—that is to say, by the formation of striae atrophicae. Striae atrophicae of this mysterious kind occur occasionally in apparently healthy individuals about the period of puberty, the skin failing to keep pace with the normally rapid growth of certain parts of the body, such as the shoulders, pelvis, and thighs. Striae atrophicae, in the absence of ordinary causes, are, however, still better known to occur in connexion with enteric fever (notably the "striae patellares") and certain other microbial infections, although even in such cases the selective distribution of the striae, and whether they are symmetrical or more or less unilateral or not, as I have elsewhere endeavoured to explain, must be due partly to mechanical causes, such as the position of the patient in bed, arrangement of pillows, etc.<sup>1</sup>

What is the cause of the relative insufficiency of the cutis in these cases to which I am referring?

Here I must speak of a condition of abnormal relative or absolute redundancy of the skin which may be contrasted with, and in some respects is the opposite of, the relative or absolute cutaneous insufficiency manifested by striae atrophicae. I refer to cutis striata or cutis sulcata—that is to say, ploughed or furrowed skin—"bulldog scalp," and cutis verticis gyrata. In these cases the scalp, especially the skin of the scalp, is locally altogether too big for the skull beneath it, and has therefore to become folded into ridges and furrows, so as to adjust itself to the surface which it covers. A local suboccipital variety of furrowed scalp may be etiologically connected with shortness of neck,<sup>2</sup> and in certain idiots complete furrowed scalp has been associated with more or less microcephaly,<sup>3</sup> though I think the microcephaly was insufficient entirely to account for the scalp condition.

In twelve cases, however, the general redundancy of the skin and subcutaneous tissue of the scalp which gave rise to a condition of cutis verticis gyrata was connected with acromegaly,<sup>4</sup> and was doubtless a manifestation of the functional (hormonic) over-activity of the anterior lobe of the pituitary gland, which is the essential cause of the main features of acromegaly, including skeletal and visceral overgrowths. Though cutis verticis gyrata occurs in relatively few cases of acromegaly, it must nevertheless, when it is present, be regarded as a manifestation of the acromegalic process, just as enlargement of certain viscera ("splanchnomegaly") must, though likewise not occurring in every case.

I suggest that, as the redundancy of the cutis present in certain cases of acromegaly is obviously due to excessive hormonal activity of the anterior lobe of the pituitary gland, or of an adenomatous tumour (an "endocrine-tumour") arising from it, the insufficiency of the cutis manifested by striae atrophicae cutis, when not caused by special distension, may be due to a defective hormonal activity of the same endocrine gland, for which, perhaps, a depressing action of the toxins of enteric fever and other microbial infections may be sometimes responsible. This suggestion is in accordance with the occurrence of obesity (of a cerebral or pituitary type) occasionally observed as a sequel to enteric fever and other microbial infections.

## DYSPHAGIA ASSOCIATED WITH ANAEMIA.

BY

A. MASON JONES, M.D., F.R.C.S. Ed.,

ASSISTANT SURGEON,

AND

ROBERT D. OWEN, B.Sc., F.R.C.S. Ed.,

CLINICAL ASSISTANT,

AURAL DEPARTMENT, CARDIFF ROYAL INFIRMARY.

THIS paper is an attempt to bring together under one heading some points of importance which have been mentioned at intervals when dealing with the subject of spasmodic dysphagia.

The symptom-complex of dysphagia and anaemia occurs practically always in women ranging between the ages of 35 and 60, and all cases present almost identical signs and symptoms. They are usually referred to as difficulty in swallowing localized to the level of the larynx, or as taking place during the first stage of swallowing; such terms as "small swallow," "inability to grip the food," or "difficulty at the back of the tongue" being given to describe the condition. The duration of the dysphagia is invariably of long standing, ranging between twelve months and eight years.

The patients appear to be anaemic, and are occasionally yellowish, but not what would be called cachectic; yet the tint is such as to compel the thought that such conditions are pernicious anaemia, subacute combined degeneration of the cord, and malignancy have to be ruled out for diagnosis. The lips are pale, and as a rule sore areas or fissures are seen in one or both corners of the mouth. Most of the cases are edentulous, the teeth generally having been extracted years previously. The tongue is smooth, glazed, and atrophic, devoid of papillae, and sometimes coated with irregular patches of desquamated epithelial cells. The pillars of the fauces are pale and glossy, the tonsils generally small and buried.

On direct examination with the oesophagoscope the same thin pale appearance of the mucosa is seen, flecked with white sticky patches of mucus. Sometimes the lumen of the gullet may appear greatly reduced by a thin membranous web, or tense bands of raised thinned mucosa may pass in various directions. Occasionally there may be complete absence of the sphincter-like appearance found in the deep part of the normal hypopharynx. In other cases a tonic contraction at the commencement of the gullet is found, making difficult the passing of the tube.

Cytological examination of the blood reveals marked decrease in the number of red corpuscles, a low haemoglobin percentage giving a colour index below 1. The differential white count shows little or no abnormality. In some cases some poikilocytosis and polychromasia can be seen. Inasmuch as no megalocytes or nucleated red cells are present, and the colour index is low, the anaemia is regarded as of the secondary type. All the cases give a negative Wassermann reaction, although on cursory examination the labial fissures and patches on the surface of the tongue suggest a possible syphilitic basis. X-ray examination of the oesophagus with a bismuth meal shows nothing beyond perhaps a slight hesitation at the level of the larynx.

In 1919 Brown Kelly and D. R. Paterson described in detail the clinical picture of this type of dysphagia. They regard it as being due to a spasm at the entrance of the oesophagus, accompanied by definite mucosal changes limited to the upper food passages. The spasm was described as being analogous to spasms seen in other parts of the alimentary canal. The condition, therefore, is associated with the question of innervation peculiar to the various parts. It was pointed out in support of this contention that a disturbance of balance may exist between the motor portion (Auerbach's plexus) and the sensory portion (Meissner's plexus). Through either being in the hyperaesthetic state the oesophagus is unduly irradiated, and may lead to abnormal local contraction and spasms. According to Chevalier Jackson, once this spasm is established it will tend to be perpetuated by the nerve cell habit, and therefore to recurrent spasms.

Furthermore, it is pointed out that mucosal changes might lead to aggravation of the disturbed nervous balance, and possibly, also, the want of resiliency in the oesophageal lining from infiltration of the underlying tunica propria. The increase in the difficulty of passage of food might act as an irritant to cause spasms.

More recently a type of this dysphagia has been described under the title of the Plummer-Vinson syndrome. The dysphagia was described as functional, but nevertheless associated with secondary anaemia and splenomegaly. It appears that the glossitis and the mucosal changes mentioned were not emphasized by Plummer and Vinson (of the Mayo Clinic); they attributed the anaemia and splenomegaly to prolonged unbalanced diet. Later Hurst, in the *Guy's Hospital Reports*, published a case which he thought corresponded very clearly with the syndrome described by Plummer and Vinson. In this case—that of a woman with long-standing history of dysphagia and anaemia—the dysphagia appeared to be definitely spasmodic. The passage of the oesophagoscope was difficult owing to the tightness of the pharyngo-oesophageal sphincter. She also had secondary anaemia and splenomegaly. The characteristic point which he mentioned was the glossitis, with the tongue covered by a thick coating of mucus. But this case differed from the Hunterian glossitis of Addison's anaemia, as in the latter condition the tongue is clean. Hurst considered this condition of dysphagia, anaemia, and splenomegaly to be primarily due to streptococcal infection, since a pure culture of *S. longus* was obtained from the spittle. The dysphagia was probably due to a reflex spasm caused by the local inflammation.

The clinical recognition of this type of dysphagia is therefore established. When first described the emphasis was laid upon the dysphagia as spasmodic in nature and not purely functional, and also accompanied by definite mucosal atrophy in the upper food passages. Later the dysphagia was described as accompanied by anaemia and splenomegaly, with the emphasis laid upon the blood changes and the splenic enlargement.

From cases seen and examined at the Cardiff Royal Infirmary it is evident that equal emphasis and attention should be paid to the dysphagia, mucosal changes, and the anaemia to make the condition a complete clinical entity. Apparently the splenomegaly is not so common. According to Plummer and Vinson, out of 69 cases only 12 had splenomegaly.

The difficulty of associating the morbid histology of the clinical facts under the one and the same pathology is recognized. To begin with, the majority of the patients are women who are edentulous. The teeth generally have been extracted years prior to the onset of the dysphagia. It would, therefore, be unlikely and untrue to regard the buccal and pharyngeal secretions as septic, and the glossitis and mucosal atrophy cannot be attributed to the localized sepsis. Yet there is the possibility of spasmodic contractions taking place at the entrance of the gullet as the result of irritation of a hyperaesthetic nervous arc. The irritation can be the result of an anatomical lesion of the oesophagus in the nature of altered mucosa. The relationship between the anaemia and mucosal atrophy and dysphagia is difficult to establish in the absence of definite localized sepsis. More work, however, is being done in the endeavour to establish a relationship between the dysphagia and the anaemia. In all the cases that came under our notice the blood counts showed that the patients were suffering from simple secondary anaemia, with the exception of one case, which was a definite primary anaemia of the pernicious type. As a matter of fact, minute examination into this patient's history showed that she had had difficulty in swallowing for years, but did not seek advice until the progressive anaemia compelled her to do so. This case is of particular interest, as the association of dysphagia and primary anaemia is rare. In the future "following up" of the dysphagic cases it will be interesting to see if any of the so-called secondary anaemic cases will have developed into a primary anaemia. Possibly some of them may have been very early cases of pernicious anaemia. The publication of details of patients suffering from dysphagia and primary anaemia is so rare that to give details of this case is not without value.

A married woman, aged 53, was first seen for general weakness, loss of appetite, and inability to swallow solid foods. Further inquiry showed that the dysphagia was occasionally associated with "ulceration" of the tongue and had been a source of discomfort to her for about three years. She paid little attention to it until her general weakness forced her to seek advice.

On admission examination showed: (1) the mucous membranes of the mouth to be very pale. She was edentulous; the teeth had been extracted years previously. (2) The tongue was red, smooth, glazed, devoid of papillae, with patches of sticky mucus present. (3) The tonsils were small and septic.

Blood examination showed poikilocytosis, misocytosis, polychromasia, and punctate basophilia. Haemoglobin 32 per cent.; colour index 1.4; red cells 2,200,000, white cells 5,000; polymorphs 57 per cent., lymphocytes 37 per cent., large mononuclears 6 per cent.; normoblasts and one or two megaloblasts seen.

The spleen was enlarged and could be felt projecting 1½ inches below the costal margin.

The central nervous system showed no abnormality. Wassermann reaction negative.

The urine contained acetone, bile salts, and pigments.

Van den Bergh test: direct—delayed positive; indirect—immediate positive.

Fractional test meal: achylia with no delay. X rays showed the stomach to be very large and atonic, reaching well down into the true pelvis. There was no irregularity or tenderness. Six hours later the bulk of the meal was in a terminal ileum.

A swab from the throat gave pure growths of *Streptococcus viridans* and *S. longus*.

The diagnosis of pernicious anaemia was made and treatment carried out accordingly.

Five months later oesilectomy was performed and a few weeks later the dysphagia became much more marked. She was therefore obliged to exist on liquid diet only. Examination of the food passages showed the usual atrophic changes. She was x-rayed again and the report was as follows: "Heart and vessels normal. Posterior mediastinum clear, and opaque food passed down the oesophagus into the stomach easily, but showed a temporary arrest at the level of the larynx. Oesophagus not dilated."

Direct oesophagoscopy showed no evidence of a neoplasm present. The hypopharyngeal mucosa appeared thin and tense. She died at home three weeks later. Unfortunately, no post-mortem examination was performed.

#### Treatment.

There is no doubt that benefit is obtained by the passage of the oesophagoscope and dilatation with bougies. The result is very often striking, as after the initial soreness following the direct examination patients are able to partake of normal meals and immediately announce themselves as being cured. Relapse, however, will result—some within three weeks, others may go on for years. When relapse does take place normal deglutition can be re-established for another period by further dilatation. It may be stated that the patient with the primary anaemia showed little improvement after dilatation.

One further point may be mentioned—the not infrequent supervention in such cases of malignant disease at the mouth of the gullet. Logan Turner and Paterson state that this happens too often to be merely a coincidence.

We are indebted to Dr. D. R. Paterson for his kindness in allowing us to make use of the cases from his department at the Cardiff Royal Infirmary.

### FIVE CASES OF ILEO-CAECAL RESECTION.

BY

C. L. ISAAC, M.B., B.Ch., F.R.C.S.Ed.,

SURGEON, SWANSEA HOSPITAL.

DURING the last six years five cases in which ileo-caecal resection has been necessary have come under my care—two for intussusception with carcinoma of the caecum, two for carcinoma of the ascending colon, and one for tuberculosis of the caecum. The immediate results of this rather formidable operation seem to me worthy of record. All the cases recovered from operation with practically no shock.

#### CASE I.

A man, aged 50, was admitted to hospital on December 7th, 1921: he had had absolute obstruction for four days, constipation for four months, with vomiting and pain after meals. He had lost a deal of weight. There was no melaena. Temperature 99° F., pulse 64. An enema produced a good result.

Operation.—On December 8th a right rectus incision was made over a mass in the caecal region. The small intestine was distended, and there was free fluid in the peritoneal cavity. An

irreducible intussusception was found with diffuse thickening of the caecum. The lower end of the ileum and the caecum, as far as it was mobile, were excised. The ascending colon was closed and the proximal end of the ileum anastomosed to the transverse colon by the end-to-side method.

The pathological report was adenocarcinoma, with marked inflammatory reaction and congestion.

Result.—A notable feature was the complete absence of shock and rapid convalescence. The patient left hospital on December 21st, within a fortnight of operation.

#### CASE II.

A woman, aged 47, was first seen as a private case, and a diagnosis of caecal tumour was made. She was admitted to hospital on January 20th, 1923, with twelve months' history of pain occurring in attacks over the umbilicus. There was no melaena or haematemesis, but she complained of diarrhoea.

Operation.—On January 23rd, through a right rectus incision, an intussusception was found similar to that in Case 1, but the ileum was laterally implanted into the transverse colon.

On section the resected portion showed columnar-celled adenocarcinoma with intense inflammatory reaction within the supporting tissues.

Result.—The patient had an uneventful recovery, leaving hospital ten days after operation.

#### CASE III.

A woman, aged 54, was admitted to hospital on January 10th, 1924, with a history of pain, vomiting, and constipation, which had recently become worse.

Emergency Operation.—There was great distension of the small gut, with ring carcinoma near the caecum. The patient collapsed somewhat, and no attempt was made to bring the growth out. The bowel was short-circuited between the ileum and the left end of the transverse colon.

Resection Operation.—On January 26th the patient was passed on to me for resection. This case showed a typical glandular distribution, as described by Dobson, and the resection included the transverse colon, as advised by him, the anastomosis being carried out as before.

The specimen was a typical ring carcinoma, and no sections were cut.

Result.—The patient left hospital within a fortnight.

#### CASE IV.

A woman, aged 49, was admitted to hospital on September 8th, 1924.

Operation.—Through a right rectus incision a one-stage Dobson resection of the ileo-caecal region with half the transverse colon was performed.

Section of the portion resected showed large masses of carcinomatous cells in the intestinal wall.

Result.—The patient left hospital within a fortnight.

#### CASE V.

A woman, aged 53, was admitted to hospital in June, 1924. She complained of pain, dull in character, in the right iliac fossa of five months' duration; she felt distended, but the bowels acted well. A fixed tumour was felt in the right iliac fossa.

Operation.—On June 18th an operation revealed what appeared to be a malignant growth in the caecum, with glands in the mesentery. The ileum was anastomosed to the transverse colon.

Resection Operation.—On July 9th the patient was passed to me for resection. The mesentery was much thickened, and numerous large glands were present, which, on section, were obviously breaking-down tuberculous ones. The resection in this case was far more difficult than in any of the cases described above, as it was deemed advisable to remove the thickened mesentery in which the glands lay, and unfortunately the ureter was injured.

Section of the portion of bowel removed showed tuberculosis to be present.

Result.—Strangely enough, this non-malignant case compares very unfavourably with the other cases in the immediate result, but possibly the eventual outlook may be better. The patient did not leave hospital until November 7th, owing to a faecal fistula, which has now almost closed; her general condition is very good.

Case iv returned to hospital on January 1st, 1925, with an implantation growth in the abdominal wall, which was removed and radium introduced. The abdominal cavity appeared to be free from recurrence. The remaining four patients speak enthusiastically of their present state of health.

It will be noticed that in two of these cases resection was preceded by a short-circuit operation, but this is only necessary in the presence of acute obstruction. The presence of carcinoma in both intussusception cases is a reminder that a wide resection is advisable in these chronic cases, as they are almost always associated with a malignant growth. For the pathological reports I am indebted to Dr. A. F. Sladden, director of the Beck Pathological Laboratory, Swansea Hospital.

Since writing the above notes I have had two cases of carcinoma of the caecum. One was inoperable, but a short-circuit operation has given relief. The other patient, a middle-aged woman, after resection has returned to her duties as a school teacher.

ACUTE DISTENSION OF THE GALL BLADDER  
(MUCCOCELE) IN A CHILD.

BY

L. STANLEY TORRANCE, M.B., CH.B.ED.,

LATE HOUSE-SURGEON, ROYAL VICTORIA AND WEST HANTS HOSPITAL,  
BOURNEMOUTH.

As this condition is not a common one I think that the publication of the following notes is on that ground justified.

A boy, aged 12, was sent into the Royal Victoria and West Hants Hospital, Bournemouth, with the diagnosis of "acute appendicitis with the appendix in an abnormal situation." He was admitted on July 12th, 1927, and seemed to be an intelligent boy; he was fair and freckled, of slight build, and with little subcutaneous fat. The skin had a slight icteric tinge, while the conjunctivae were definitely yellow. The pulse was 75 to 80, temperature 98° F. in the axilla and 99° in the rectum. He complained of pain in the right upper quadrant of the abdomen.

The history of the present illness was as follows: On July 4th he suffered from general malaise and feverishness, went to bed, and the doctor was summoned. On July 7th clay coloured stools were passed. On July 10th he had pain in the upper abdomen, unlike colic, and severe flatulence. On July 11th he vomited; pain was becoming localized in the right iliac fossa and a tender swelling was felt there by the patient. On July 12th the temperature was subnormal, he had abdominal pain and flatulence, and the right rectus muscle was tender and rigid. There was a yellow tinge in the skin and conjunctivae. His appetite was good, and there were no subjective phenomena. The bowels, which had been regular, had recently become constipated, and the motions were clay coloured.

Examination of the abdomen showed very little movement of the upper part, and none at all in the right upper quadrant. On very lightly stroking the abdomen with the finger-nail very definite hyperaesthesia was found over the gall-bladder region, at the lower edge of the tenth costal cartilage. The skin of the right upper quadrant could be pinched up between thumb and forefinger more easily than that on the left side, although pain was caused—proving the right rectus to be contracted. Palpation confirmed the contraction and elicited tenderness, especially pronounced over the gall-bladder region, where pressure caused a sudden cessation of respiration. It was thought that an underlying tumour could be felt here, but owing to the rigidity it was impossible to be certain of this. There was a pronounced absence of tenderness in every other region of the abdomen, even on deep pressure, and in the right iliac fossa the vertebral column could be palpated without causing pain. Percussion yielded a dull note over the gall-bladder region, extending from and continuous with the liver dullness for a distance of approximately two inches from the costal margin. Rectal examination gave a negative result.

The patient's food consisted chiefly of bread, butter, and potatoes. He had had measles, chicken-pox, and tonsillitis; for the last-named he had undergone tonsillectomy eight years ago.

The urine, which was of a dark amber colour, green on surface, gave an alkaline reaction; specific gravity 1020; there was no albumin or sugar, but bile pigment was present (Poam, and Gmelin's nitric acid tests). The respiratory system was normal. A soft mitral systolic murmur was heard. There was a slight generalized itching of the skin.

The diagnosis was: acute gall-bladder lesion; ? appendicitis and coexistent catarrhal jaundice. Immediate operation was decided upon.

*Operation.*

Mr. W. S. Richardson operated on July 12th. The anaesthetic was the chloroform and ether sequence. A paramedian incision was made through the upper right rectus. On opening the abdomen an enlarged, much distended, but not inflamed, gall bladder was found. This was incised, allowing the escape, under tension, of clear mucus. A soft rubber catheter was stitched into the gall bladder. No obstruction of the bile ducts could be felt. The appendix, in a normal situation, was inflamed; it had a bulbous tip, with a constricted part proximal to the swollen extremity.

Appendectomy was performed. The other abdominal organs were all found to be healthy, and the abdomen was closed. No bacteriological examination was undertaken.

*Progress.*—Bile drained freely through the catheter, which in due time came out, leaving a biliary fistula which gradually closed, while the faeces regained their normal colour. The boy was discharged, cured and well, on August 10th.

*Remarks.*

The chief point of interest in this case is the occurrence of the condition in a child, following upon what must almost certainly have been an attack of catarrhal jaundice complicated by a concomitant attack of appendicitis. At least, in view of the condition of the appendix as found at the operation, it is to be assumed that the pain and swelling in the right iliac fossa, experienced the day before admission, were due to an attack of appendicitis. Another interesting feature of the case is that this same attack of appendicitis should have completely subsided by the time

of admission, so that no tenderness whatsoever could be elicited in the right iliac fossa. It is to be assumed that this acute mucocele formation was caused by the spread of the catarrh to the cystic duct, where the swelling of the mucous membrane was such as to occlude the lumen of the duct, thereby preventing the escape of the mucus secreted by the mucus-secreting cells of the lining of the gall bladder, thus causing the rapid distension of the bladder and giving rise to the referred abdominal pain and rigidity.

I am indebted to Mr. Richardson for very kindly permitting me to publish this case.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## ECLAMPSIA.

I have, during the year, treated in the County Maternity Hospital, Bellshill, Lanark, 27 cases of eclampsia, with a maternal mortality of 7.4 per cent.

The treatment, as carried out at present, is as follows: If the patient, when admitted, has recovered consciousness the stomach tube is passed and gastric lavage practised until the fluid siphoned off returns clear. A dose of chloral hydrate and potassium bromide, 25 grains of each, is given, after which a rectal enema containing magnesium sulphate 1/2 oz. in 10 oz. of sterile water is administered. The patient is then given 4 oz. of compound senna mixture with 1/2 oz. of Epsom salts dissolved in it, which is followed by a dose of 2 minims of croton oil in half a drachm of olive oil. If the pulse is full and bounding or over 110, veratrine 1/2 c.cm. is given hypodermically. If the fits recur, or if the patient is unconscious on admission, the same procedure is carried out, save that the croton oil is given by the rectum, and the chloral and bromide in similar doses at intervals of one hour until three doses have been given. Large doses of morphine sulphate are undesirable, as it appears to me to depress the heart's action (as is evidenced by the early appearance of cyanosis), and tends also to increase intestinal stasis. At the same time I am of the opinion that small doses of morphine (1/6 grain) are beneficial at the beginning of treatment in severe cases.

No attempt is made to deliver the patient unless labour is well advanced in the second stage, and then deep ether anaesthesia is produced before delivery is attempted.

All cases were treated by the routine described. The ante-natal cases numbered 2; one died, the other went home at her own risk after treatment, to come in for confinement at full term. The number of neo-natal cases was 20, and of post-natal cases 5.

### THE PATIENT'S COMFORT AFTER PROSTATECTOMY.

A METHOD of nursing cases of prostatectomy has recently been demonstrated to me by the matron of our local nursing home, Miss A. A. Frazer, which is, I believe, original, and certainly contributes in no small measure to the patient's comfort. It is also a great economy, both as regards dressings and the laundry bill.

For the first few days, of course, the patient remains practically dry, but, as soon as the suprapubic drainage tube comes away, then the patient, lying in Fowler's position, is placed sitting on a well-inflated rubber bed-pan. A piece of gauze is placed over the wound with the ends brought down on each side to a point between the legs. Over this comes a piece of wool, about six inches square, folded at the lower end to a point, and lastly, a piece of jaconet, about ten inches by eight inches, also folded to a point between the legs. A strip of bandage is passed round the waist and tied in front over the jaconet, the upper border of which is folded over it. The urine will now all drain into the rubber bed-pan, which is removed for emptying several times in the twenty-four hours, the bed remaining dry. The patient's scrotum, groins, and perineum are kept well smeared with ointment.

The rubber bed-pan used must be kept almost fully inflated and well powdered. The patient soon learns to sit well back on it, and remains on it throughout his convalescence in bed. It can be obtained from Messrs. Rothband and Co., Bent Street, Manchester, price 21s.

Rotherham.

W. STANLEY WILDMAN, F.R.C.S.Eng.

### DERMATITIS HERPETIFORMIS IN A CHILD.

The following unusual case of dermatitis herpetiformis seems to be of general interest.

In December, 1927, I was called to see a boy, aged 4½ years, who had a temperature of 99.4° F., a corresponding increase in the pulse rate, redness of the throat, and an erythematous rash. Three days later a number of small vesicles were seen on the forehead and eyelids; these burst and disappeared, leaving the skin blotchy. On the following day a bulla about the size of a marble developed on the left forearm, accompanied by a larger one on the chest, which became haemorrhagic and burst, leaving a raw surface. This was followed by the appearance of bullae covering the body and limbs and attaining, in some cases, quite large dimensions. The boy was admitted to Leeds Infirmary under the care of Dr. Ingram, who confirmed the diagnosis of dermatitis herpetiformis. The history at this time of a multiform eruption, papular, vesicular, and bullous—with the vesicles, some of which were haemorrhagic, being characteristic of the condition. The fluid from the bullae was sterile and showed an excess of the eosinophile cells, which also occurred in the blood to the extent of 3 per cent.

The child was put on arsenic in small doses and responded well to treatment.

The chief point of interest in this case is the occurrence of dermatitis herpetiformis at such an unusual age, since it is almost exclusively a disease of adult life. Some writers have suggested that the condition results from worry or shock, while others attribute it to a toxin arising from faulty metabolism. My observations in this case, especially at its onset, when it showed an erythematous eruption, accompanied by papules, which later became vesicular, seemed to correlate it with varicella. Such a relation would involve a similarity of origin—namely, infection by an ultra-microscopic virus. This seems the most rational etiological explanation to me.

I am indebted to Dr. Ingram for his help in furnishing me with reports of the blood and serum from the bullae.

Morley, Yorkshire.

S. WIGGON, M.B., B.Ch., L.M.

### REMOVAL OF A FOREIGN BODY FROM THE STOMACH OF AN INFANT.

In view of the satisfactory sequel and the novelty of the procedure adopted to remove a safety-pin from the stomach of an infant the following case may be worthy of record.

An infant, 2 months old, was brought to hospital, having swallowed a safety-pin half an hour previously. X-ray examination showed the pin with its upper end at the level of the cricoid cartilage; it was hanging with the hinge downwards, and the engaging clip and point were directed upwards. The child was not distressed. The same evening the child was anaesthetized. An oesophagoscope, specially designed to close an open safety-pin,

was passed, and the clip of the pin was sighted. The tube had then to be withdrawn to re-establish the child's airway, and a smaller tube was introduced. Examination was made along the length of the oesophagus, but the pin could not now be seen; the fluorescent screen, however, showed it lying in the fundus of the stomach. It was deemed inadvisable to make further attempts at removal that evening.

The next morning an X-ray plate revealed the pin in the same place at the fundus of the stomach. The child was again anaesthetized, but took the anaesthetic none too well. A soft rubber catheter, size 16 English, was passed down the oesophagus into the stomach, and the abdomen was opened through an incision splitting the upper part of the left rectus muscle. The end of the catheter and the unclipped pin were grasped through the unopened stomach wall; the point was passed through the wall of the catheter and the pin was closed. The stomach wall was then pinched up to make sure that it was in no way caught. The catheter, bearing the pin, was then withdrawn along the oesophagus through the mouth, and the abdominal wound was closed with through-and-through sutures. The child was returned to the ward in a satisfactory condition and made an uninterrupted recovery, leaving hospital with the wound healed, and quite well. The pin was an such in length.

There seem to be several points worthy of note in the procedure detailed above. The additional shock attendant on opening a hollow viscus was avoided. In any case this is quite a serious undertaking, and would almost certainly have killed the child. The method of removal adopted might be employed for any object, sharp at one end and blunt at the other, which has passed as far as the stomach. It is obvious that while this procedure can be used in the case of an object lodged in the stomach it is advisable not to delay until it might pass further.

I can find no mention in the literature of this method having been suggested or attempted. The procedure was conceived and executed by Mr. L. R. Broster, to whom with Mr. Lees, I am indebted for permission to publish this case.

W. B. R. MONTEITH, F.R.C.S. Ed.

Queen's Hospital for Children, Hackney.

## Reports of Societies.

### THE USE AND ABUSE OF ULTRA-VIOLET RADIATION THERAPY.

At the meeting of the Medical Society of London on February 13th the subject for discussion was the use and abuse of ultra-violet radiation therapy. Mr. H. W. CANNON, the president, was in the chair.

Dr. LEONARD HILL, in introducing the subject, began with a reference to other radiations. Much nonsense, he said, was talked about infra-red radiation therapy. The infra-red rays were nothing but heat rays such as were obtained with a hot-water bottle or fomentations. They had exceedingly little power of penetration, and were absorbed especially by the water in the outer layers of the skin. The visible rays—light—had greater power of penetration, especially the rays in the red portion of the spectrum. If a powerful source of incandescent rays were used, and the infra-red rays cut off so as to avoid overheating, a penetration of some depth below the dermis might be secured. The energy of the visible rays was turned into heat in the blood, and possibly had some other action in the blood of which nothing at present was known. The ultra-violet radiations might be of long, medium, or short wave-length. They covered the region from 4,000 to 2,000 Angström units. There was no need to consider radiations beyond the 2,000 limit, because these were absorbed by the oxygen of the air. The sun gave no rays shorter than about 2,900 Angström units, but artificial sources like mercury vapour lamps or long-flame arcs extended the spectrum right down to the 2,000 limit. The biological evidence showed that the region round about 3,000 had the principal action on the skin in causing sunburn and in activating ergosterol and producing antirachitic vitamin. The shorter the wave-length the greater the killing power for bacteria and infusoria. The long ultra-violet radiations, from 4,000 upwards to 3,000, were not absorbed to any great extent by living tissues; at about 3,000 they passed through the horny layer of the epidermis, being largely retained by it, and were almost completely absorbed by the living cells of the dermis. The maximum biological action was at about 2,970, just where

the high sun reached on a very clear day. Artificial sources acted mostly with rays shorter than 3,000, and the sun with rays mostly longer. Pigment was not a great protection against ultra-violet, but it was a defence against the visible rays; the pigment was in the deeper cells of the epidermis, and its function was to prevent over-heating of blood by light. Of all the methods of stimulating the defensive mechanism of the body none was more excellently adapted than ultra-violet radiation, which could be very carefully graduated and distributed over such areas as one pleased. Harm was done by over-dosage, just in the same way as exhaustion was produced by excess of sunlight. The temporary discomfort or illness which persons might experience after over-use of ultra-violet baths was of the same character as that which followed imprudent exposures at the seaside; but in acute disease such as phthisis much harm might be done.

Dr. W. J. O'DONOVAN said that the fact that light treatment had been going on at the London Hospital since 1900 without a day's discontinuance—except for the deplorable behaviour of the electricians in the general strike—was greater proof of its efficiency than any mass statistics of therapeutic results, which might rightly be distrusted. Furthermore, artificial sunlight therapy, both by arc and mercury vapour lamps, was introduced into the hospital in 1922, and there was not the slightest indication that it was failing to produce its cures. The speaker then mentioned a number of skin conditions in turn. Light therapy for lupus must be both general and local. The destructive work of the tubercle bacillus was slow, and the cure must necessarily be tardy also. Nodule after nodule of lupus could be picked out by Finsen light, or by its more destructive, less elegant, and less manageable substitute, the Kromayer lamp, and the time required could be shortened considerably and the cure made more certain by the daily administration of active light therapy. If light had served only to banish  $\alpha$  rays from the therapeutic field of lupus it would have justified its place. The immediate results of  $\alpha$  rays were often gratifying, but the later results of atrophic, vascularized, pigmented, and ugly scars were not pleasing. As to lupus erythematosus, he could confirm from his own experience what was the traditional teaching of the London Hospital clinic—namely, that light treatment for this condition was a waste of time and effort. His impression of the value of actinotherapy in cases of acne was distinctly discouraging. In widespread cases of psoriasis he had completely cleared the lesions and obtained two years' freedom from relapse by a steady daily dosage from the mercury vapour lamp. Nevertheless, each case had relapsed to a greater or less extent in the course of time. It was his practice always to combine light therapy with vigorousunctions of ointment and the use of the rest of the dermatologist's armamentarium. Actinotherapy had proved to be a most valuable weapon for combating pruriginous conditions. It was his opinion that many of these, whether accompanied by cutaneous manifestations of lichenization or no, were psychic in origin. In this he included cases of pruritus ani, pruritus scroti, pruritus capitis, and such conditions as lichen axillaris and lichen circumscrip-tus. All these benefited patently by general daily light baths, and where the irritation was intense and localized the patients all derived benefit from as large a local dose of mercury vapour radiations as could be tolerated without acute discomfort. It was with pleasure that in this field a dermatologist was able to turn from  $\alpha$ -ray treatment to local actinotherapy, with results which were gratifying to the patient and a relief to the conscience of the operator. He was doubtful as to the value of light therapy in ringworm. In certain cases of eczema, following the exhibition of ultra-violet light, there developed occasionally a most intractable exfoliative dermatitis. In seborrhoea, apart from simple lesions which responded quickly to sulphur ointments,  $\alpha$ -ray epilation was of primary importance, and after that relapse could be prevented and cure hastened by the general administration of very small doses of ultra-violet radiation, not exceeding half a minute to each side of the body daily in the first instance. In three cases of post-herpetic pain in elderly patients the condition became quite tolerable within a week of daily administrations of local ultra-violet radiation baths.

He had also found actinotherapy useful in dealing with the wide wounds after surgical incision for carbuncle.

Dr. C. B. HALL took some exception to Dr. Hill's remark that the rays at the long end of the spectrum had no effect; it was to that region that the rays used in diathermy belonged. With regard to abuses of ultra-violet radiation, he thought these came under three heads: extravagant claims, injudicious doses, and home use. To claim cures of cases, unsupported by scientific measurement and accurate clinical data, and based on insufficient numbers, was in his opinion dangerous, misleading, and liable to bring the subject into disrepute. With regard to injudicious dosage, this implied a failure to realize the true needs of the patient. Patients might be classified as those requiring sedative, tonic, and counter-irritant treatment. It was possible to use ultra-violet radiation in a sedative way and also in a counter-irritant way, but the essential preliminary before its use was not only accurate diagnosis of the disease, but a careful assessment of the condition of the patient; and, further, it was necessary to know the lamp, and what was exactly required of it. He thought there was no doubt that ultra-violet radiation could light up a quiescent phthisis, or give rise to cataract, or increase a bacterial infection. In a case of chronic long-standing arthritis of the hip, following a hunting injury, after the patient had made considerable progress with diathermy the speaker thought he would try ultra-violet radiation. The effect was to precipitate a definite and acute attack of appendicitis. With regard to home use, he was not a party to the general condemnation of the lamp at home, nor to its general recommendation. Ultra-violet radiation, which was capable of altering the lime salts of bones in a very short period, of altering the nutritive value of milk in nursing mothers on the one hand, and of lighting up phthisis on the other, was a potent therapeutic agent not to be lightly installed in every room. But geographical and other reasons might bring about a set of circumstances in which, after accurate diagnosis and determination of dosage, and instruction—given an intelligent patient—he might be allowed to use the lamp at home. Any employment of the lamp which went beyond those limits he would condemn. If the uses of ultra-violet radiation were not to be outweighed by its abuses it was necessary that the knowledge with regard to it should be on firm grounds and the technique capable of accurate description. Dr. Hall ventured with some hesitation to make one observation—namely, that in his own experience he was finding a curious difference in clinical results obtained, say, with the mercury vapour lamp at a great distance, at a medium distance, and, with the Kromayer or Finsen-Reyn lamp, in close proximity. This was a matter which called for more investigation. During the last five years four thousand fractures, major and minor, had passed through his department, and there had not been one single failure of union. In cases of delayed union, sent from infirmaries or from the country, success had eventually been obtained by the use of light combined with other means. In some of the cases union had been delayed for a long period, the longest being twelve months.

Dr. H. HALDIN-DAVIS said that in his department at the Royal Free Hospital Dr. Colebrook had made a careful investigation of the treatment of varicose ulcers by ultra-violet radiation, with regard to which large claims had been made. She had found the radiation practically inert in this particular condition.

Dr. DAVIN BARCROFT said that in Vincent's angina he had tried ultra-violet radiation in two cases, with good results in one. In acne his results were distinctly disappointing, and generally, he thought, ultra-violet radiation was rather like a summer holiday, in that it was a tonic at the time, but its effects evaporated.

Dr. A. C. ROXBURGH spoke of the detection of ringworm hairs in the scalp by ultra-violet radiation. The patient was taken into a dark room and placed underneath a mercury vapour lamp, with the hood closed save for an opening about 2 inches in diameter, across which was a piece of Wood's glass—a dark violet glass containing oxide of nickel. This glass allowed to pass certain of the long ultra-violet rays, from 3,600 to 3,300 Angström units. If the hand were placed under this emission the skin would

be seen to fluoresce slightly, and the nails much more. When the head of a child afflicted with small-spored ringworm—which was the common kind of ringworm in this country—was exposed, the normal hairs looked as though they had been slightly dusted with flour, but the ringworm hairs showed a brilliant greenish light, which enabled one to pick out a single ringworm hair in an otherwise healthy scalp. This method had been found useful in detecting early infections in brothers and sisters of patients obviously infected. It was as well to remember that iodine would completely prevent the fluorescence, and silver nitrate would stop it to a certain extent.

Dr. G. VILVANDRE defended x-ray therapy from some of the criticisms of Dr. O'Donovan. In skilled hands he thought x rays as good an agent in the treatment of tuberculous glands of the neck as ultra-violet radiation. He emphasized the need for careful diagnosis of the condition before patients were treated with the ultra-violet lamp.

Mr. ZACHARY COPE commented on the fact that no constructive views had been put forward as to the scientific measurement of the radiation emitted by the lamps. He had not heard a word in that discussion as to the safe dosage of a local lesion. It seemed to him that much remained to be stated with regard to intensity, distance, and the area which it was safe to illuminate at one time.

Dr. LEONARD HILL, in reply, said that in the measurement of ultra-violet radiation biological methods must be the final standard. To find out the exact dosage for a patient nothing was easier than to put some kind of a bandage on the arm or elsewhere, and expose through small holes in the bandage for different periods. The dose which produced the smallest amount of erythema should be used to start with. For estimating the dosage of the lamps the acetone-blue method was accurate.

Dr. O'DONOVAN, also in reply, said that any man who would learn to use ultra-violet radiation should go to a clinic and instruct himself in its traditions. These things were only learned by the experience of actually seeing cases handled in the mass.

## OCULAR COMPLICATIONS OF ENCEPHALITIS LETHARGICA.

At a joint meeting of the Sections of Neurology and Ophthalmology of the Royal Society of Medicine on February 9th, with the president of the Neurological Section, Professor EDWIN BRAMWELL, in the chair, a discussion was held on the ocular complications of encephalitis lethargica.

Dr. JAMES COLLIER, opening for the Neurological Section, emphasized the difficulties in diagnosis, mentioning especially cases in which no hint as to the nature of the disease was given during the early days of the illness. Prefrontal tumours with rapid onset might closely simulate encephalitis lethargica. The speaker maintained that the characteristic symptoms of sleepiness, ophthalmoplegia, Parkinsonism, spontaneous movements, dysuria, and constipation were due to the position of the lesions in the brain stem and not to any specific quality of encephalitis lethargica. He reported two fatal cases with such a syndrome, one of which was encephalitis lethargica and the other a rapidly growing soft tumour. Poliomyelitis and tuberculous meningitis had also to be distinguished, but examination of the cerebro-spinal fluid would help considerably in the diagnosis. Dr. Collier then dealt with lesions of the nervous mechanism which subserved vision. Mentioning first the occipital lobes, the speaker said that he had not seen any case in which "cortical blindness" had been definite. One patient had a persistent left homonymous hemianopia, persisting altogether unchanged for four years, showing a lesion in the visual path. With regard to the optic nerve, one patient presented during the acute stage the syndrome of retrobulbar neuritis. Papilloedema he had only seen in one case in any degree in which the diagnosis was verified pathologically; minor degrees of swelling of the disc did not occur very often. The causes of such papilloedema might be, firstly a rise in intracranial pressure, and secondly that the neuritis, from local inflammation, came far enough forward to be seen at the optic disc. Ophthalmoplegia was met with in two

forms: paralysis of any of the peripheral oculomotor nerves might occur, or a nuclear ophthalmoplegia, hardly ever complete, affecting both eyes, leaving the optic axes unparallel, might be found. Dr. Collier said that nystagmus was not common. He had seen it in one case of acute cerebellar encephalitis. Herpes certainly occurred, but the speaker had not actually seen a case.

Mr. F. A. WILLIAMSON-NOBLE, for the Section of Ophthalmology, referred in the first place to recent pathological work on the disease which had an ophthalmological basis, since it began with Grüter's work in 1910 on vaccinia of the cornea in rabbits. The outcome was the indication of a close relation between the virus of herpes simplex and the virus of encephalitis lethargica, the principal point of difference being the enhanced neurotropic activities of the encephalitis virus. Coming to the clinical side of the subject, the speaker enumerated the eye lesions occurring as a sequel to encephalitis lethargica. These comprised jerky eye movements, lack of blinking, blepharoclonus, partial ptosis, unequal pupils, deficient accommodation, deficient convergence, nystagmoid jerking, diplopia with squint, lid retraction, ocnogyric crises, sluggish reaction to light, Argyll Robertson pupil (rare), squint (rare), tapping the globella making the eyes flicker, and "blinking sign" (Kinnier Wilson) on lateral deviation. Of these signs Mr. Williamson-Noble emphasized loss of power of convergence as being one of the commonest associated with the Parkinsonian syndrome: this was also one of the commonest eye troubles in paralysis agitans. He mentioned also the curious tonic eye fits or ocnogyric crises: these consisted of spasmodic attacks of conjugate deviation of the eyes, most frequently vertical, often associated with a marked emotional factor. The speaker referred to the occurrence of papilloedema, mentioning four cases, in all of which the diagnosis of encephalitis lethargica was found to be incorrect at autopsy. Optic neuritis was also very rare, and the absence of optic disc changes appeared to be a negative sign of value in the diagnosis of encephalitis lethargica.

Dr. A. FEILING gave some details of his personal experience of ocular complications of encephalitis lethargica. He described four cases of ocnogyric crises, stating that this complication had only appeared in this country during the last two years. He agreed that the presence of papilloedema was against the diagnosis of encephalitis lethargica. With regard to the various ocular palsies, during the acute stage both the intrinsic and the extrinsic muscles were commonly involved. In the sequels or in the chronic form of the disease the commonest palsy was one of the intrinsic muscles, and consisted of deficient contraction of the pupil on accommodation.

Dr. J. R. PEARCE dealt with two points in connexion with encephalitis lethargica. He emphasized the high percentage of wrong diagnoses made among cases of which the cerebro-spinal fluids or brains had been referred to him for examination. He also considered some of the arguments concerning the relation of the virus of herpes simplex to that of encephalitis lethargica.

Mr. M. L. HINE described a case of a young man, aged 24, in whom, as a complication of encephalitis lethargica, a left hemianopia developed, complete in the lower quadrant and partial in the upper quadrant. This had persisted unchanged for three years.

Dr. W. J. ADIE emphasized the number of wrongly diagnosed cases, and commented on the difficulty of mentioning definite ocular signs which were distinctive, since so many ocular complications might occur. He thought the chief sign was lack of convergence and absence of contraction of the pupil on accommodation.

Dr. GORDON HOLMES enumerated some of the positive ocular signs which assisted in the diagnosis of encephalitis lethargica in the acute and chronic stages. He mentioned the "reverse Argyll Robertson" pupil as being common, and agreed that papilloedema was rare.

The PRESIDENT added two definite signs which, in his opinion, occurred in practically no other disease. One was the loss of upward movements of the eyes and the other was a curious oscillation of the eyeballs when the patient attempted to perform certain movements of the eyes.

## THE FUTURE SCHOOL MEDICAL OFFICER.

At a meeting of the Medical Officers of Schools Association on February 10th, with Dr. ELWIN T. NASH in the chair, a paper was read by Dr. ALFRED A. MUMFORD of Manchester Grammar School on the school medical officer of the future.

Dr. Mumford began by saying that before certain problems which were implicit, if not explicit, in school life could be properly solved, medical help and inquiry were needed. Many of these matters were of long standing, the residue of problems left unsolved in the past, or the solution of which had been forgotten or neglected. They could not be settled properly even now without recognizing that mind and body worked in harmony, and that mental and physical activity derived their energy from some common source and must be considered together. The separation between mind and body was not only artificial, but was of recent growth, dating from the time of Descartes. It was not found in Greek medicine or philosophy, and in modern times the failure of mechanistic methods to solve completely physiological problems was becoming generally recognized. The association between the arts of medicine and of teaching had long been intimate. It certainly existed at the time of the Renaissance, though it broke down during the eighteenth century, when English education fell to its lowest level. It entered again into association with education in the early part of the nineteenth century, when it was recognized that many young children in the newly started Sunday schools and in the national schools were suffering seriously in health on account of their employment in factories. Medical intervention had a large share in directing the movement which led to the Factory Acts. In recent times there had been a tendency to prolong publicly provided education well into adolescence. This not only involved fresh conditions of school strain, but should bring medical officers of public boarding schools into closer relations with those of day secondary schools than had hitherto been the case. The greater attention now paid to the adolescent opened up some important questions in relation to physical training, the strain of school and examination work, and the formation of standards by which to judge vocational aptitude and future occupation. In dealing with each of these questions a more intimate relation between the medical officer on the one hand, and the teacher and physical trainer on the other, was necessary. Educational practice in the past had only been modified when advances in medical science succeeded in convincing the general public of the necessity for such modification. The speaker recalled how Dr. Pridgeon Teale introduced the question of over-pressure among teachers and scholars at the Huddersfield sanitary conference in 1883, when he was supported by Dr. (afterwards Sir) Clifford Allbutt and other leaders of the medical profession. Dr. Crichton Browne (as he then was) was asked by the Government to report on school over-pressure, and his condemnatory report was strongly endorsed by the National Union of Teachers. Dr. Francis Warner endeavoured to prove that nervous instability and defects were associated with observable defects of body-build or development, and his 100,000 observations on children were supported by the British Medical Association. Dr. Warner appeared as expert witness before Royal Commissions and committees appointed to consider the exclusion from ordinary schools of children suffering from special defects, and for these children special schools were established. A Royal Commission appointed in 1902, following the introduction into English elementary schools of a model course of physical training, found that many children were unfit for any form of physical training on account of their poor health. An interdepartmental committee, appointed to inquire into the alleged physical deterioration of the nation, issued in 1904 a report which was strongly supported by the Anthropological Institute, and public opinion compelled the Government, against its wish, to include in an Act making provision for feeding necessitous school children some method of medical inspection. The lack of organized and influential medical opinion had, however, caused some of the important recommendations contained in the report of the Interdepartmental Committee on

National Deterioration to be shelved. Consequently the national school medical service became organized, not as a special branch of medicine engaged in the positive assessment of health and vigour, nor as a national register of sickness of children, but as a branch of public preventive medicine engaged in the detection of existing ailments and physical defects. Dr. Mumford insisted that this limitation had obscured the necessity for any study of the essential differences, all within the range of health, which only became marked during adolescence, though they occurred to a slight degree in early childhood. Consequently a new position had arisen to-day for the school medical service, which needed the adoption of positive anthropological methods in studying individual differences of race, capacity, and temperament. All these should be taken into account in any standardization of physical, as well as mental, training. Other guiding principles were also needed to help the school medical officer in assessing physical fitness for early promotion into advanced forms in secondary schools, the capacity of the pupil to withstand without injury the strain of preparation by long hours of home work, and also in assessing health in terms of future occupation. The physical basis for such guiding principles was more likely to be found in tests of functional activity than in single body measurements. Finally, school work might be considered in terms of a modified Ohm's law, in which the teaching provided was the potential or "electromotive force," the individuality of the boy himself was the "resistance," and the knowledge or capacity displayed was the issuing "current."

Dr. ELWIN NASH referred to the mixed groups of boys with whom Dr. Mumford had to deal at Manchester Grammar School, and said that his own Lancashire experience had shown that there were many boys who came from poor homes, such as colliers' cottages, and took prominent places in school, although they had never been really up to nutritional standard. He could call to mind boys who had taken the highest educational honours in school, and afterwards in the university, who had been always more or less underfed, with a physical condition below par.

Dr. NARRN DOBBIE spoke of the necessity of keeping in mind both the physiological and the psychological aspects. The standpoint of the pure psychologist was too narrow for the school medical officer to adopt. Psychology, however, useful, was only part of the picture, which embraced physiology as well.

Dr. G. E. FRIEND said that at Christ's Hospital he measured the boys three times a term, and once a year made a more complete measurement and graded every boy. He found now a much more sympathetic attitude than formerly on the part of the school authorities to this side of the school medical officer's work.

Dr. A. I. SIMEX said that the ideal thing would be to establish a national laboratory where a statistician and a pathologist would work in collaboration and to which school statistics could be sent for analysis and record. The results would be extremely valuable for comparative purposes two or three generations hence. He himself had accumulated eighteen years' statistics at Rugby, all filed for reference, but the difficulty was to know when and how to make use of them.

Dr. J. A. H. BRINEKER referred to the importance of the school medical officer being closely acquainted with the work of the physical instructor, and to a certain extent with the work of the psychologist. The medical officer of the future would be not merely one who attended to ailments, but one who correlated his own results, and those of others, over a much wider field of investigation.

Dr. MUMFORD gravely doubted whether there was any proper height-weight index for all children. He also thought that ideas as to the amount of food needed were apt to be too rigid. The amount of food differed very much according to the boy's build. It was possible for one boy to be on restricted diet without a great deal of harm, while in another, with a larger body surface, twice the amount of food would be needed. He added that it was useful to study the skin as an organ, in the same way as one would study the lungs. He had found a high degree of correlation between mental ability and skin activity.

### MULTIPLE UTERINE FIBROID TUMOURS.

At the annual meeting of the North of England Obstetrical and Gynaecological Society in Manchester on January 27th, Dr. H. LEITH MURRAY (Liverpool) was elected president for the ensuing year.

Dr. K. V. BAILEY showed a specimen of multiple uterine fibroids, with torsion of the pedicle of one, and gave the following clinical details.

A woman, aged 36, with a normal menstrual history and no menorrhagia or leucorrhoea, had definite dysmenorrhoea of the congestive type. She had noticed a "lump" in the right iliac region during the last twelve months. This had occasioned no pain or other untoward symptoms until six months ago, when an attack of acute abdominal pain occurred at the close of a menstrual period: it passed off after a few hours, and there was no recurrence of pain until a week before admission, when a similar attack occurred, but of greater intensity. During the few days prior to admission the patient had experienced some degree of dysuria. There were no symptoms relative to pressure on the rectum. The previous medical history contained no points of importance relative to the present condition. A firm, hard, mobile mass was found occupying the right iliac region; its origin from the pelvis was traceable. Vaginal examination revealed the cervix to be of a smooth and conical type; the mass, palpable abdominally, was continuous with two irregularly rounded, hard, but mobile pelvic tumours, which appeared to be situated in front of a somewhat bulky uterus and on either side of it. A diagnosis of solid ovarian tumours, with torsion of the pedicle of one of them, was made. On opening the abdomen the uterus was found to be the seat of numerous fibroids. The two masses which had been palpated vaginally were two subperitoneal fibroids springing from the antero-lateral aspect of the uterus, and possessing definite pedicles. Torsion of the pedicle of one of them had occurred. The uterus and its appendages were removed by subtotal hysterectomy.

The specimen shown by Dr. Bailey consisted of a relatively small uterus, which contained numerous small interstitial fibroid tumours, and one larger fibroid, the size of a tangerine orange, growing out from its right lateral aspect. The two large subperitoneal fibroids sprang from the antero-lateral aspect. Torsion of the pedicle of one of these had occurred, with resultant haemorrhage into the substance of the fibroid. The other subperitoneal fibroid, the size of a foetal head, had undergone hyaline degeneration, and there was evidence of calcification in its substance. Dr. Bailey remarked that in this case there was no history of menorrhagia, and this notwithstanding the fact that numerous interstitial fibroids were present. He had operated recently on three other cases of multiple uterine fibroids, exhibiting the tumour in all its situations, and in none had menorrhagia been a symptom.

#### *Dystocia due to Vaginal Atresia.*

Dr. K. V. Bailey also described a case of atresia of the vaginal vault causing dystocia in a 3-para, aged 33, who had had two premature stillborn children. She had been operated upon for prolapse twelve years previously, and a repair operation, most likely amputation of the cervix, had been performed two years before the present date. The menstrual history was normal.

The patient, when two months pregnant, had suffered from persistent vomiting; the urine contained diacetic acid. She gave a history of premature rupture of the membranes in two previous pregnancies, with consequent stillbirths. The Wassermann reaction was negative when she was six months pregnant, but there was some vaginal discharge, and antiseptic treatment was ordered. Dr. Bailey saw the patient first when she was in labour at term, and the uterus was contracting strongly and frequently. The presentation was a vertex left occipito-anterior, but the foetal head was mobile at the pelvic brim. The foetal heart sounds were audible. The patient was becoming distressed, with a pulse rate of 126. On vaginal examination there was no cervix or external os to be felt; the vaginal vault was entirely closed, and a band of scar tissue ran somewhat obliquely in an antero-posterior direction across the middle of it. During examination the uterus again contracted strongly, and the vaginal vault bulged under tension on either side of this scarified area; it was obvious that there was considerable thickness of tissue composing the vault of the vagina. Dr. Bailey delivered a healthy male child by Caesarean section and removed the uterus, cutting across the dilated lower segment as close to the vaginal vault as possible, and rendering the space between this line and the vaginal vault as antiseptic as possible. The patient had since progressed very favourably.

Mr. J. E. STACEY (Sheffield) described a similar case which he had delivered by Caesarean section. Dr. F. H. LACEY (Manchester) recorded a case of this kind in which rupture of the uterus occurred early in labour and hysterectomy was performed. Professor DONALD (Manchester) attributed the presence of excessive scar tissue in the

vagina following colporrhaphy to the use of strong and harmful antiseptics. Professor FLETCHER SHAW (Manchester) mentioned recent cases of sloughing and stenosis of the vagina following the use of methylated spirit as an antiseptic.

#### *Puerperal Ovarian Thrombo-phlebitis.*

Dr. S. B. HERD described a case of puerperal ovarian thrombo-phlebitis.

A married woman, aged 30, had had four previous confinements, all normal except for oedema of legs during the last three months of the fourth pregnancy. During the present pregnancy the ankles were oedematous in the course of the last two weeks. She was delivered fairly easily at home by high forceps, but she was admitted to hospital on the third day after delivery with a temperature of 100.4° F. and a pulse of 120. There was slight jaundice; she looked ill, and was anaemic. There was oedema in both ankles. The lochia was normal. The uterus was tender but well involuted, and no swellings were palpable. The urine contained no pus, but there was a feeble growth of staphylococci. The temperature fell on the next day, and the uterus continued to involute; at this time the blood culture was negative. On the eleventh day another rigor occurred, but there were still no localizing symptoms; she was given serum, quinine ergot, and pituitrin. On the twelfth day there was tenderness in the popliteal space and left calf, but no vein was palpable; there was tenderness in the left fornix, but no swelling. The uterus was normal. On the following day a blood culture showed streptococci in chains. On the fourteenth day the abdomen was opened and the left ovarian vein was found to be thrombosed, the thrombus extending almost, if not quite, up to the renal vein. Ligature and excision of the left ovarian vein was performed, and the left ovary was removed; no other abnormality was found in the abdomen. The patient suffered severely from shock after the operation and died fifteen hours later, in spite of blood transfusion. There were no further rigors.

Dr. Herd discussed the literature on the subject, and mentioned the difficulty of early diagnosis. The conclusions he drew from the case were: (1) the importance of early diagnosis; (2) that complete excision of the vein was preferable to ligature; and (3) laparotomy might be performed earlier in obvious cases of pyaemia where the patient was rapidly becoming worse in spite of active treatment.

Professor MILES PHILLIPS (Sheffield) did not consider that laparotomy was justifiable in a serious case of puerperal septicaemia unless the diagnosis was certain.

### TUBERCULOSIS OF THE SKIN AND TENDON SHEATHS.

The annual meeting of the Devon and Exeter Medico-Chirurgical Society was held at the Royal Devon and Exeter Hospital on January 26th, when Dr. R. EAGER inducted Mr. A. L. CANDLEN, the newly elected president, into the chair.

Mr. Candlen showed a case of tuberculosis of the skin of the finger and of the synovial sheath of the flexor tendons in a man aged 33, a herdsman. The history dated back to July, 1927, when he remembered having received a bruise on his right wrist following a blow from a cow's leg. He had been unable to work since August 20th. Fluid had been present in the anterior common synovial sheath since early in September. The skin had improved under treatment by ultra-violet rays, but the synovial sheath remained swollen and tender. Dr. Solly had found tubercle bacilli in the inflamed skin in September, and this had added a medico-legal interest to the case in that tuberculosis had been prevalent in the wrist in question. Mr. Candlen concluded that from his own experience excision gave bad results owing to the risk of subsequent adhesions; he had in view the possibility of aspiration followed by an injection of ether into the synovial sheath.

Dr. MILLER MUN suggested a prolonged course of ultra-violet rays before trying any drastic remedy, but Mr. CANDLEN considered that from the wage-earning point of view this was undesirable.

#### *Gas Gangrene Following Fracture.*

Mr. R. WAYLAND SMITH reported a case of gas gangrene in a boy, aged 3½, who was admitted to hospital on January 17th with a compound fracture of the left forearm, having fallen through the roof of a shed where roots were stored, thus causing contamination of the wound. The wound was cleaned under a general anaesthetic, irrigated

with flavine, and free drainage was established. On the evening of the next day there was a rise of temperature to 104° F., with a pulse rate of 160 and respirations of 40, the boy being restless and delirious. There was no crepitation in the tissues, but in view of all the circumstances a guillotine amputation was performed through the forearm above the site of the injury. On January 19th the condition showed considerable improvement, but at night the temperature rose again to 104° F., with rapid pulse and respirations. The stump of the forearm was hard and swollen; there were a few bubbles on its surface, although no crepitus could be detected, and there was an offensive smell. A guillotine amputation was now repeated through the upper arm, and on examination of the portion of the limb removed the appearance and odour resembled that associated with putrefaction for several days. No gas formation could be seen, but *B. welchii* was recovered from cultures of the muscle.

The PRESIDENT discussed the deterrent effect of acids in the growth of *B. welchii* and the possibility of treatment on these lines. Mr. N. LOCK cited three cases due to road accidents during recent years. Recovery had ensued without recourse to serum treatment. Mr. WAYLAND SMITH, in his reply, mentioned the improvement in cases of intestinal obstruction with toxicæmic symptoms following the injection of anti-gas gangrene serum.

#### Diagnosis of Hodgkin's Disease.

Mr. WAYLAND SMITH showed a middle-aged man with a tumour in the left side of the neck which presented difficulties in diagnosis. There was a history of the removal of a lump some twenty years previously. The present mass was situated in the submaxillary region and in the upper part of the anterior triangle. There were two enlarged glands the size of pigeon's eggs in the posterior triangle, and these were removed for diagnosis. Enlarged glands were also detected on the right side of the neck, but not in the axillæ or groins. The man was somewhat cyanosed, and his appearance suggested hyperthyroidism. Section of the removed glands showed some fibrosis and slight endothelial hyperplasia; the findings did not suggest Hodgkin's disease, tuberculosis, or malignancy. The blood count was a little low in red cells, the leucocytes being 10,000 per c.mm.; the differential count of the latter was normal. Mr. Wayland Smith considered that in spite of the pathological report the case was one of Hodgkin's disease. Removal was not devoid of risk, and, in addition, the skiagram indicated similar masses in the mediastinum. He was inclined to trust to x rays in treating the case.

Dr. MILLER MUM thought that Hodgkin's disease responded well to treatment with x rays as a rule, and that the diagnosis might be solved thus in this instance.

#### Puerperal Pyæmia.

Mr. WAYLAND SMITH also showed a case of puerperal pyæmia in a primipara aged 28. He said that the temperature had risen on the fifth day after an instrumental delivery, had reached 103° F., and had then subsided, but had never since become quite normal. On getting up at the end of three weeks she had complained of pain in the left side and also on straightening the left leg when walking. There was a history of profuse night sweats. When examined on January 19th a tender cylindrical swelling could be felt in the line of the descending colon; it was not unlike the condition noted with cases of colitis, but no swelling was found in the left lateral fornix. She was admitted to hospital and treated with intrauterine injections of glycerin. On January 22nd the temperature had risen to 104° F. and there was a rigor. On January 23rd the abdomen was opened and the left ovarian veins were found thickened and matted; the overlying colon was adherent and inflamed. The ovarian veins were ligatured high up and the uterus explored, but with negative findings. The patient now appeared to be progressing slowly towards recovery, but could not yet be considered out of danger.

#### Hypernephroma.

Dr. FAYLE SEALE read notes of a case of hypernephroma occurring in a man, aged 50, who had complained of pain in the leg for some twelve months, but had attributed this

to varicose veins. Dr. Seale, on seeing him, had diagnosed myeloma of the upper third of the tibia, and the limb had been amputated subsequently by Mr. Candler. The tumour was soft and friable, and sections corresponded histologically with those of hypernephroma. Of further interest in this case was the fact that although the man appeared now to be perfectly well in all other respects a definite tumour could be felt in the area of the right kidney.

#### Polypoidal Proliferative Colitis.

Dr. SOLLY showed, in association with Dr. C. H. MILLER, a specimen of polypoidal proliferative colitis from a man, aged 50, who had been admitted to hospital on December 12th, 1927, and who had died four days subsequently from severe hæmorrhage from the rectum. There had been a history of diarrhoea for three weeks prior to admission, with offensive watery stools containing blood but no mucus; the man had not been abroad. Cultures from the stools produced *B. coli* and Friedländer's bacillus. The blood count showed a leucocytosis of 18,000, of which polymorphonuclears formed about 55 per cent. At the necropsy the whole portion of the pelvic colon and rectum and parts of the transversus and ascending colon were found to be the seat of chronic polypoidal nodules. The colon was full of altered blood, hard scybala being present both in the colon and the caecum.

#### THE TRIAL OF MARY BLANDY.

At a meeting of the Brighton and Sussex Medico-Chirurgical Society on February 2nd, the president, Dr. DONALD HALL, in the chair, Dr. L. A. PARRY read a paper on the "Trial of Mary Blandy for the murder of her father by poisoning with arsenic." Dr. Parry first referred to various earlier cases of murder by poison, including the Glenconner case in 1580, the case of Henry Robson, who poisoned his wife in 1593 by the introduction of arsenic into the vagina, and the Overbury mystery of 1615; he also mentioned the inquest on Miles Sindercome, who, for high treason, was condemned to be "hanged on the gallows till he be half dead," and then to be cut down and his entrails and bowels taken out and burnt in his own sight, and who committed suicide by poison to avoid this punishment. Sir Richard Napier and Dr. Fern had given evidence which was very vague, indefinite, and unsatisfactory. Dr. Parry said that the trial of Mary Blandy was the first case of murder by poison, so far as he could ascertain, in which medical evidence was given to prove the cause of death. The girl was accused of the murder of her father in order to obtain his money and marry her lover. She received some powders from the latter which she gave her father. According to her statement she believed she was giving a love philtre to him to make him like her lover better. The evidence for the prosecution indicated that this was not so, but that she deliberately poisoned her father, with full knowledge of her act. The chief medical witness was Dr. Anthony Addington, the father of the celebrated statesman Lord Sidmouth. He gave evidence to the effect that he had analysed some of the powders sent to Miss Blandy and that they contained arsenic. But though a necropsy was performed no attempt was made to examine the viscera for arsenic. The tests recommended at this time by the celebrated Dr. Black of Edinburgh were many, and not very different from those used at the present time; they included a modified Reinsch's test. Dr. Parry interpolated the remark that the best and most delicate test known at the present time was the electrolytic, which showed the presence of very minute quantities of the mineral; it had been first used quantitatively in the trial of the Scddons in 1912. Dr. Parry, continuing, said that Mary Blandy was found guilty and hanged at Oxford. In those days the criminals—more often than not there was a batch of criminals—were drawn in a cart to the place of execution through a crowd of morbid sightseers, and the halters were adjusted by the hangman. The ear in which they stood, or the ladders on which they had climbed, were then removed, and they were left to die of strangulation, which often took a considerable time. Occasionally the executioner took pity on the victims and hung on to their legs, thus shortening the death agony. Dr. Parry remarked that to-day the death factor was not strangulation; but the sudden jerk of the fall caused a fracture dislocation of the cervical vertebrae, and death was instantaneous. Dr. Parry added that the guilt of Mary Blandy had usually been accepted by the many who had written on her case, but he mentioned a letter written by her just before her death, and a speech made by her on the scaffold, as was the custom at the time. In both of these she had firmly declared her innocence of any wrongful intent in giving the powders to her father.

## Rebicus.

### THE NORMAL AND MORBID GALL BLADDER.

Is a fine volume entitled *La vésicule biliaire* Professor CHIRAY of Paris, Dr. I. PAVEL of Bucarest, and Dr. A. LOMON, radiologist to the Paris hospitals, give a full and well illustrated account of the anatomy and physiology of the gall bladder, and of the pathology, clinical picture, and treatment of its diseases. In addition to much personal experience, the work of others has been fully acknowledged, and copious bibliographies are attached to the various sections. The thorough character of this work is illustrated by the full and critical account of the new information that can be obtained by the Meltzer-Lyon method (which in Germany is associated with the name of Stepp) in combination with radiological observations, provided in a chapter occupying some sixty pages.

Of the five parts of this important monograph the first is devoted to anatomy, histology, embryology, and physiology, and the second to the methods of investigation, such as cholecystography. In the third part, dealing with the gall-bladder syndromes, hepatic colic is first discussed, and it is pointed out that in the past this has been too closely connected with the presence of calculi and so to the, at any rate partial, neglect of its occurrence in other morbid conditions of the gall bladder. After detailing several hypotheses to explain the mechanism of biliary colic, such as those of Tripiet and Pariot (who referred it to local peritonitis), Aschoff, and Hartmann, the authors adhere to the old view that contractions of an abnormal gall bladder are responsible. The second gall-bladder syndrome described is "diarrhée prandiale," which is largely quoted from M. Linossier of Vichy; it is explained as depending on a sudden and single evacuation, instead of the usual prolonged passage, of bile into the duodenum after taking food; for its treatment a dose of thebaine and belladonna before food is recommended. The syndrome "gall-bladder insufficiency" is then dealt with, meaning thereby absence or diminution of its contractile power and of its concentrating action and reservoir function—in fact, the clinical aspect of cases often diagnosed as cholecystitis or gall stones.

In the fourth part, headed pathology of the gall bladder, the great subject of cholecystitis is described under the two heads of calculous cholecystitis, which includes cholelithiasis, and the non-calculous form. No fewer than ten different hypotheses about the formation of gall stones are passed in review. Chiray's view is that there is primary functional disturbance of the liver cells causing a diminution of the amount of soluble cholesterol in the bile, which may be related to an insufficient formation of bile acids. The strawberry gall bladder, for which the authors prefer Bergeret and Dumont's name of lipoid cholecystitis, is admirably described with black-and-white illustrations and a coloured plate of the microscopical appearances of the lipoid-laden villi. The tumours and parasitic affections of the gall bladder are considered, and there is an account of biliary peritonitis without any perforation of the biliary tract.

The concluding section on treatment is divided into an account of Lyon's non-surgical drainage of the biliary system and remarks on the surgery of the gall bladder from a medical point of view, such as the indications for and choice of operation and the medical sequelae of cholecystectomy. The book thus provides an extremely clear and exhaustive source of reference on a subject that tends to become more surgical, at least in the therapeutic aspects.

Dr. MOSES BEHREND of the Mount Sinai Hospital, New York, has brought out a generously illustrated work on *Surgical Diseases of the Gall-bladder, Liver, and Pancreas and their Treatment*.<sup>2</sup> Beginning with an account of the

development, anatomy, and physiology of the liver and pancreas, their pathology and the clinical pictures presented by their diseases are passed in review. Then follows a full account of the operative technique of the gall bladder and bile ducts, including anaesthesia, to which a short chapter is devoted. A special chapter is given up to cholaemia and its operative treatment, and a comparatively short account, occupying 14 pages, suffices for the diseases and treatment of pancreatic disease. Lastly, there is an investigation into the results of ligation of the hepatic artery in various animals, which, though rather outside the scope of the work, is interesting as containing these experimental observations. They were undertaken after the experience of tying the two ends of the severed hepatic artery in a boy, run over by a wagon, who died fourteen days later with symptoms resembling those of acute yellow atrophy of the liver.

### RECENT ADVANCES IN PSYCHOLOGY.

To many members of our profession a casual acquaintance with modern developments of psychology—the sort of knowledge picked up by turning over the leaves of the technical journals when waiting in the library for the books one has ordered—is not very reassuring. If psycho-analytical literature not infrequently produces the impression of some religious sect performing an impressive rite in a wholly unintelligible language, and we, sighing for the relative intelligibility of arithmetic, and remembering Charles Darwin's faith in the rule of three, turn to the psychologists who do offer us statistical tables, we find that these tables are entrenched in equations, and, what is worse, that the engineers of these entrenchments have but a poor opinion of one another's efforts. In fact, if the palace of the sleeping psycho-analytical beauty is overgrown with metaphysical brambles, that of *g*, the "central factor" of intelligence or temperament (as there are two, perhaps we should say *g* and *g'*), seems to be overgrown with algebra. We gather from a recent memoir by Professor Karl Pearson and Miss Moul (sternly critical as it is of others' algebra) that it may be well worth while hacking a way through the forest, for *g* (or *g'*) may really be a very attractive sleeping beauty. But this will require a very sharp axe, and much skill in wielding it, and to the man who is no more interested in algebra than in metaphysics Professor CYRIL BURT's Henderson Trust Lecture<sup>3</sup> will be a godsend.

There is not much algebra in Professor Burt's lecture—we even fear that some of his simplifications will be unfavourably received by the statistical mathematicians—but he does succeed in very lucidly explaining what the statistical psychologists are trying to do—why *g* is important, and how such investigators as himself and Professor Spearman—to whose work he pays a high and well deserved tribute—are attempting to replace vague appreciations of qualities by precise measurements. We do not think that the most sceptical reader of Professor Burt's essay could doubt that in the assessment of the intelligence side of human capacity, particularly perhaps that of children of school and pre-school age, a great advance has been made in the last quarter of a century. It is, no doubt, too much to hope that in our time examinations of the schoolmaster's type will be replaced, as measures of intelligence as distinct from *acquirements*, by a less painful and more precise test, but it is certainly not too much to say that such a reform is no longer wholly Utopian. Progress on the side of temperament has also been made, but is less unequivocal.

With the studied and, no doubt, illogical moderation of the average Englishman we cannot but hope that there may be a blending of the two most active schools of modern psychology; that it may be possible to introduce into the intensely individualistic quest of the "unconscious" a thought more quantitative precision, so that research in that field may be a little less mystical, and that the statistical study of mental capacities may be informed with medical experience, and perhaps elevated above—be it spoken with reverence—mathematical controversy. Some of the work of the Industrial Fatigue Research Board—

<sup>3</sup> *The Measurement of Mental Capacities*. By Cyril Burt, M.A., D.Sc. The Henderson Trust Lectures, No. VII. Edinburgh and London: Oliver and Boyd. 1927. (Cr. 4to, pp. 52; 14 figures. 6d.)

<sup>1</sup> *La vésicule biliaire*. Par M. Chiray, I. Pavel, et A. Lomon. Paris: Masson et Cie. 1927. (Roy. 8vo, pp. vii + 568; 4 coloured plates, 130 figures. 70 fr. sans majoration.)

<sup>2</sup> *Surgical Diseases of the Gall-bladder, Liver, and Pancreas, and their Treatment*. By Moses Behrend, A.M., M.D., F.A.C.S. Philadelphia: F. A. Davis Company. 1927. (Med. 8vo, pp. 278; 101 figures. 4 dollars net.)

such, for instance, as the recent study of telegraphists' cramp by Dr. Culpin and Miss May Smith—suggests that there is a real possibility of harmonizing the individual and the statistical methods.

### HERNIA AND HERNIOPLASTY.

COMPARATIVELY few publications on the subject of hernia have appeared in recent years, but a monograph by Mr. E. M. COWELL on *Hernia and Hernioplasty*<sup>1</sup> indicates that we have not reached finality in regard to its origin or its operative treatment. Mr. Cowell sets out very clearly the present position, and has, moreover, succeeded in introducing new interest and thought into a corner of surgery which was tending to become a backwater. Thus, for example, he describes a method of using fascial grafts in herniotomy which he has himself elaborated. An introduction by Sir ARTHUR KEITH supplies guidance and stimulation for the young surgeon in solving problems. The author bases his subject on anatomical observations, and adopts Sir Arthur Keith's conviction that the muscles guarding the hernial orifices are kept closed by a shutter-like action during exertion. After some historical considerations he discusses the anatomy, physiology, development, and pathogenesis of the various forms of hernia, and provides many excellent illustrations. Then follows a short chapter on recent work relating to fascial grafts and sutures. The clinical side is fully dealt with, comparative statistics are given, the author's technique is described, and closing chapters on the medico-legal aspect of hernia, and on hernia in the services, complete a valuable study. It must be admitted, however, that the author's technique is somewhat difficult to follow from his illustrations taken from actual operations, and it is possible that simple diagrammatic sketches would have served his purpose better in this respect.

### HISTORY OF MEDICINE.

WE welcome the appearance of a fine volume on the history of medicine,<sup>2</sup> by Dr. ARTHURO CASTIGLIONI, professor of that subject in the University of Padua, to whose historical contributions we have drawn attention on several previous occasions (see *JOURNAL*, 1923, i, 433, ii, 624, 1108; 1926, i, 329).

Although the number of persons interested in the history of medicine is undoubtedly as great in Italy as elsewhere, it is more than three-quarters of a century since a complete work on the subject has appeared in that country. Professor Castiglioni has made good this defect by undertaking a work which deals with the history of medicine from prehistoric times down to the present day, including an account of the healing art in Mesopotamia, Ancient Egypt, Judea, Ancient Persia and India, pre-Columbian America and the Far East, classical antiquity, the Middle Ages, the Renaissance, and subsequent centuries.

Professor Castiglioni has combined a broad and philosophic outlook with the mastery of an enormous amount of detail, which he has so skilfully arranged as never to be tedious. It is gratifying to find that the author has done ample justice to British medicine, as shown by his appreciation of Harvey, Sydenham, the Hunters, Jenner, Lister, and of British medical historians such as Friend, J. F. Payne, Osler, and Allbutt, as well as living workers in this country. The text is liberally interspersed with excellent reproductions (some of them in colour) of contemporary sculpture, buildings, manuscripts, books, pictures, and portraits relating to the history of medicine. A special bibliography is appended to each chapter, and a general bibliography of books dealing with the history of medicine, its special branches, or particular diseases will be found at the end of the book.

Professor Castiglioni is to be warmly congratulated on his work, which deserves to rank among the most authoritative and readable books on the history of medicine.

<sup>1</sup> *Hernia and Hernioplasty*. By Ernest M. Cowell, D.S.O., M.D., B.S., F.R.C.S. With an Introduction by Sir Arthur Keith, F.R.C.S., F.R.S., London: H. K. Lewis and Co., Ltd. 1927. (Demy 8vo, pp. xvi + 128; 72 figures, including 8 plates. 5s. net.)  
<sup>2</sup> *Storia della medicina*. By Arturo Castiglioni. Milan: Società Editrice "Unitas," 1927. (6½ x 8½, pp. xi + 959; 369 figures. L.120.)

### CIRCULATORY DISORDERS.

IN a small volume on hypertensive diseases<sup>3</sup> Dr. ESKIL KYLIN discusses arterial hypertension in the light of recent clinical and experimental work. He recognizes three main types. The first is essential hypertension, insidious in onset and characterized by absence of oedema or renal symptoms, a normal capillary pressure, and by abnormally large variations of systolic arterial pressure. This type he believes to be due to a disturbance of the vegetative nervous system of unknown origin. Such patients live for fifteen or twenty years and, if they do not die from cerebral haemorrhage or cardiac failure, end in a condition of renal insufficiency. The second type is hypertension associated with acute glomerular nephritis; in this the capillary pressure is raised, oedema is present, and the daily blood pressure variations are normal or but slightly exaggerated. The disease is considered to be dependent on a general capillary damage due to circulating toxic substances and associated with a functional arteriolar spasm. While very few of such patients die in the acute attacks and a number are left with permanent kidney damage, the majority recover entirely. Cases of hypertension with chronic kidney disease form the third type, called permanent hypertension, and this is held to be a later stage of either of the first two classes. Such in outline is the author's working hypothesis. It is evident that no clear conception of arterial hypertension has yet been reached, and that almost nothing is known of either its mechanism or causation.

In a book describing the peripheral circulation and its disturbances,<sup>4</sup> Dr. A. DUMAS of Lyons brings together a large series of clinical observations, many of which have been published previously in French medical journals. The various maladies are described largely in terms of blood pressures and of indices obtained by the Pachou oscillogram, an instrument which has not found much favour in this country. Throughout the book there is no departure from the somewhat obscure terminology that is commonly associated with descriptions of such vascular disturbances, and, as too often happens, the reader is left at the end wondering what exactly is meant. It is difficult to avoid the feeling that much information might have been gathered from all this varied clinical material if different methods of study had been adopted. The book reveals clearly how little is known about the diseased conditions affecting the peripheral vessels.

### CRIMINOLOGY.

TWO more volumes have been added to the Notable British Trials series, both dealing with accusations of murder, in each of which the accused was a young woman of pleasing appearance, involved in the troubles of love affairs. In the Scottish case the verdict was "not proven"; and there is little doubt that, if the law had allowed it, the same verdict would have taken the place of "not guilty" in the English case. The *Trial of Madeleine Smith*<sup>5</sup> in 1857 is interesting for the light it throws on mid-Victorian mentality, apart from the interest of the question how 82 grains of arsenic found their way into the stomach of the lover, Emile l'Angelier. There is entertainment also in the florid defence by the Dean of Faculty, John Inglis, who, after praising the moderation of the Lord Advocate in his speech for the prosecution, proposed to "tear to tatters that web of sophistry in which the prosecutor has striven to involve this poor girl and her sad, strange story." The *Trial of Adelaide Bartlett*<sup>6</sup> in 1886 raised the extraordinary question whether it was possible for a poisoner to get a large quantity of chloroform down the gullet of her victim; and if Adelaide Bartlett was guilty, we agree with Sir James Paget that, once it was all over, she should have told us, in the interests of

<sup>3</sup> *Die Hypertonie-Krankheiten*. Von Dr. Eskil Kylin. Berlin: J. Springer. (Roy. 8vo, pp. viii + 168; 22 figures. R.M.8.30.)

<sup>4</sup> *La Circulation Sanguine périphérique et ses Troubles*. Par Dr. A. Dumas. Paris: G. Doin et Cie. (6½ x 9½, pp. iv + 376. 40 fr.)

<sup>5</sup> *Trial of Madeleine Smith*. Edited by Tennyson F. Jesse. Notable British Trials. Edinburgh and London: W. Hodge and Co., Ltd. 1927. (Demy 8vo, pp. xi + 415; 10 plates. 10s. 6d. net.)

<sup>6</sup> *Trial of Adelaide Bartlett*. Edited by Sir John Hall. Notable British Trials. Edinburgh and London: W. Hodge and Co., Ltd. 1927. (Demy 8vo, pp. 402; 8 plates. 10s. 6d. net.)

science, how she did it. In this case Sir Edward Clarke enhanced enormously his reputation by the skilful defence he put up. Both the trials displayed the difficulties and weaknesses of medical evidence. In both the summing-up was masterly; but we prefer the Scottish Lord Justice Clerk's charge in the Madeleine Smith case to that of Mr. Justice Wills. The Right Hon. John Hope told the jury that they were not to give the slightest weight to the personal opinion of the Lord Advocate in prosecuting, or to the moving declaration of conviction of innocence by the Dean of Faculty for the defence. Perhaps the saddest thing in these trials is to watch the attempt of counsel to instil by rhetoric into the minds of twelve presumably rational beings that black is white or vice versa.

### NOTES ON BOOKS.

ONE of the most popular among the Students' Aids Serles is the *Aids to Ophthalmology*,<sup>10</sup> the seventh edition of which by Mr. BISHOP HARMAN, is to hand. It is more than twenty years since the writer of this notice first made the acquaintance of the work as a medical student; it gave him the maximum of necessary information in the minimum space, and he has never ceased to advise students preparing for the final examination to use it as it is meant to be used. As an epitome of theoretical ophthalmology it would be hard to beat; the descriptions are clear and accurate, while the liberal provision of illustrations adds enormously to its value. The present edition has undergone revision. More space is now devoted to the subject of glaucoma, while two new chapters have been added—one on the eye signs of general disease and the other on the blind. Both are excellent, particularly the latter. The author is to be congratulated, and we are sure that his little book will continue to appeal strongly to students, who, as a rule, resemble Mrs. Gamp in liking their beer drawn mild. If they feel the need of audit ale there are plenty of larger textbooks on the market which supply it.

Dr. HOPEWELL-ASH's small book *On Middle Age and Keeping Young*<sup>11</sup> is written in simple language and contains the laws of physiological righteousness and much common sense for the readers—the lay public—for whom it is obviously suited. It is a revised and popular edition of an earlier book with a slightly different title, and contains a new chapter on auto-intoxication, which, with nerve strain, the author regards as the greatest factor making for ill health in men and women in the prime of life. If complimentary, he is fortunately very premature in his reference to "no less an authority than the late Sir Archibald Garrod," to whom he ascribes a dictum on "gout which probably came from his father, Sir Alfred Garrod."

The little work on *The Catholic Nurse*,<sup>12</sup> by Father RICHARD J. MURPHY, S.J., consists of twenty chapters dealing with the nurse's training, work in hospital and private houses, her religious duties, including baptism of infants and preparation for communion of the sick and extreme unction, and her attitude towards non-Catholic patients.

<sup>10</sup> *Aids to Ophthalmology*. By N. Bishop Harman, M.A., M.D. Cantab., F.R.C.S. Eng. Seventh edition. London: Baillière, Tindall and Cox. 1923. (Fcap. 8vo, pp. viii + 226; 112 figures. 3s. 6d. net.)

<sup>11</sup> *On Middle Age and Keeping Young*. By E. L. Hopewell-Ash, M.D. London: Mills and Boon, Ltd. 1923. (Cr. 8vo, pp. 121. 3s. 6d. net.)

<sup>12</sup> *The Catholic Nurse: Her Spirit and Her Duties*. By Richard J. Murphy, S.J. 1927. Sydney: Angus and Robertson, Ltd., and the Cornstalk Publishing Company. (Cr. 8vo, pp. 179. 4s. 6d.)

### PREPARATIONS AND APPLIANCES.

#### TABLOID QUINOPHAN.

WE have received from Messrs. Burroughs Wellcome and Co. a specimen of "tabloid quinophan," which is a preparation of phenyl cinechoninic acids or cinechophen (*U.S.P.*, X). This drug has an established reputation for two therapeutic actions—namely, its power to increase the elimination of uric acid, and its antipyretic action. It appears to be increasing in popularity fairly steadily. The makers claim that the standard of purity of tabloid quinophan is exceptional, and higher than that required by the *British Pharmacopoeial Codex*.

#### A FOOD BALANCE FOR DIABETICS.

A spring balance for weighing food for diabetic patients, made by Messrs. George Satter and Co., Ltd., is being shown on their stand at the British Industries Fair at Castle Bromwich, February 20th to March 2nd. It is a small, compact, light balance, registering up to 8 ounces.

## THE HEALTH OF THE SERVICES.

### THE NAVY.

#### ANNUAL REPORT FOR 1925.

As usual, the annual report on the health of the navy<sup>1</sup> is a year late as compared with those of the other fighting forces. This delay precludes a comparison of statistics, and the out-of-date figures and remarks have ceased to be of real interest. It might perhaps be suggested that if the present office staff is unable to cope with the work there are several "unemployed" officers who might thus be usefully "employed." Besides being out of date the navy report is also the most expensive of such publications.

Over seventy pages of the report are devoted to statistical tables of varying interest, but no information is given as to rejection of recruits. The report as a whole is an improvement on previous issues in that the general remarks are more informative, but even in its present form it cannot be considered entirely satisfactory. Too many pages are occupied in putting into words the bare numerical facts which are later repeated in tables.

The report for 1925 deals with the health statistics of a total force of 89,950, an increase of 2,330 compared with 1924. The ratio of admissions was 464.78 per 1,000, a decrease of 21.46. The average number of men sick daily was 21.45 per 1,000, a decrease of 2.18; the death rate was 2.82 per 1,000, a decrease of 0.27, and the number finally invalided, 1,412, giving a ratio of 15.69, also shows a decrease.

The chief causes of admission to the sick list were injuries (7,133 cases), catarrh (6,058), gonorrhoea (3,971), and tonsillitis (2,746). There is a decrease in nearly all the diseases caused by infection. Vaccination, and revaccination every five years, probably accounts for the fact that only 2 cases of small-pox occurred, both on foreign stations; the total number of vaccinations amounted to over 21,000. An epidemic of enteric in the *Emperor of India* accounted for 17 of the 32 cases; the outbreak was probably due to contaminated food supplied by the canteen while at Kavala, was confined to boys belonging to one mess, and was generally mild in type, due to preventive inoculations within five to nine months prior to the outbreak. The routine measures taken to prevent enteric diseases include lectures and notices, the chlorination of drinking water and sterilization of milk, the prohibition of uncooked vegetables, the regular medical examination of all ratings engaged in handling food, the bacteriological examination of those who have recently had enteric fever, and prophylactic inoculation. Influenza shows a large decrease, great attention having evidently been paid to preventive measures. There is a slight increase in the incidence of pneumococcal infection of the lungs, but a decrease in that of rheumatic fever. Pulmonary tuberculosis accounts for 221 cases, with 197 invalidings and 31 deaths, a slight increase in incidence compared with the average for the four years 1921-24. The East Indies Station shows the highest case ratio and the North America and West Indies Station the lowest; the ratings mostly affected were Kroomen, the regulating staff, telegraphists, supply staff, and cooks—that is, excluding coloured ratings, those working between decks. Venereal diseases show a case ratio decrease of 10.13 compared with 1924, and of 27.35 compared with the previous four years' average. The methods adopted for the prevention of these diseases, in addition to lectures, recreation, and physical training, include improvements in the means of early diagnosis, facilities for returning on board at night in foreign ports, and the provision of anti-venereal outfits and ablution cabinets. Data are being collected as to the relative merits of calomel cream or a 1 per cent. mercuric iodide soap as a prophylactic. Diseases of the respiratory system show an increased incidence of 3.59 per 1,000, and diseases of the digestive system an increase of 2.48, as compared with 1924. Alcoholism accounts for 40 cases, with 10 invalidings. General injuries account for 272 cases, with 111 deaths, 69 of which were due to suffocation occasioned by the loss of Submarine M1, and 26 from drowning. Local injuries amounted to 7,583 cases, with 58 invalidings and 10 deaths. There were 3 cases of wounds in action and 10 of suicide.

The total number of deaths was 131, the causes being suffocation (69 cases), drowning (26), wounds, fractures, etc. (24), suicide (10), and burns and scalds (2). The chief causes of invaliding were diseases of the eye (256 cases), pulmonary tuberculosis (197), and diseases of the ear (144). Sequelae of gonococcal infection, which usually head the list of invalidings, now take fifth place with only 63 cases. Thirty men were invalided on account of having refused surgical operations, chiefly for hernia.

<sup>1</sup> *Statistical Report of the Health of the Navy for the Year 1925*. London: H.M. Stationery Office. 1927. Price 4s. 6d. net.

With regard to dentistry, it is recorded that there is a general improvement in the quantity of work performed and an increasing demand for treatment. Definitely better dental condition of personnel, with evidence of greater care being taken with regard to oral cleanliness, is especially noticeable among boys who have recently left the training centres and whose dental condition is noted as very satisfactory. Of newly entered recruits about 31 per cent. required extensive and 63.5 per cent. limited dental treatment to render them fit for service.

### THE ARMY.

#### ANNUAL REPORT FOR 1926.

THE Army Medical Department at the War Office is again to be congratulated on its endeavour to issue the annual reports on the health of the army before their value has diminished.

The report for 1926, which has just been issued,<sup>1</sup> contains, as in previous years, the various statistical tables which are essential for administrative purposes and yearly comparison, while the attempts hitherto made to render each an instructive volume for all medical officers and a periodical contribution to scientific literature on the diagnosis, research, and treatment of disease in the army are continued. This function of the report is of much importance, and a copy should be in the hands of every medical officer to enable him to obtain up-to-date official information connected with diseases in the army.

#### Admission Rates.

In general the health of the troops at home and abroad in 1926 was satisfactory, although there was a slight increase in the admission rate compared with the previous year. The death rate remained the same, and there were further reductions in the invaliding and constantly sick rates.

The principal causes of admission to hospital, invaliding, and inefficiency on account of sickness in hospital, are tabulated, and the notes on diseases draw particular attention to the loss to the army occasioned by the more common ailments. Two charts showing the admissions for prevalent diseases at home and abroad, except India, are published for the first time, with a view to impressing upon all medical officers "the necessity for constant and unremitting attention to the research, investigation, and treatment of these ailments." It is pointed out that the ratio per 1,000 of men constantly in hospital for the more common diseases was 1,217.79 in 1925 and 1,154.95 in 1926, while the number of working days lost to the army at home on account of these diseases was 444,493 in 1925 and 421,557 in 1926.

The admission rate for officers, with an average strength of 9,833, was 298.4 per 1,000, compared with 296.3 in 1925. The death rate fell from 4.44 per 1,000 to 4.27 in 1926, while there was also a decrease in the constantly sick rate from 13.46 per 1,000 in 1925 to 12.76 in 1926. The admission rate for other ranks, with an average strength of 189,906, was 454.8 per 1,000, compared with 446.2 in 1925.

The chief causes of admission to hospital were similar to those of 1925, malaria heading the list with 10,159 admissions, the ratio per 1,000 showing an increase from 51.8 to 53.5. Venereal diseases (7,795 cases) come next, with a decrease of 795 cases on the 1925 admissions. The ratio per 1,000 has fallen to 31.2 for gonorrhoea and 3.8 for syphilis. Then follow tonsillitis (6,430 cases), inflammation of areolar tissue (4,434 cases), influenza (4,360 cases), bronchitis (3,116 cases), and sprains (2,571 cases). The ratio per 1,000 increased in influenza and tonsillitis, and decreased in bronchitis and sandfly fever.

While some commands show an increased admission rate on that for 1925, others show a marked decrease, such as North China, from 999.4 in 1925 to 693.0 in 1926, and West Africa, from 1,016.8 to 881.0.

The death rate remained the same as in 1925.

The ratio per 1,000 of invalids discharged from the army fell from 11.12 in 1925 to 10.68 in 1926. The chief causes were again inflammation of the middle ear, tuberculosis, and valvular disease of the heart; the two last causes, however, show a slight decrease. Investigations are still proceeding with a view to reducing the wastage caused by middle-ear disease.

#### Sickness and Loss of Working Days.

As already pointed out, particular attention is drawn under notes on diseases to the part played by the commoner ailments among troops. Along with two charts, supplementary figures are given showing the average constantly sick and the total working days lost both at home and abroad, emphasizing their

importance from the point of view of military efficiency. Venereal diseases at home show an average constantly sick of 316.61, with 115,563 working days lost, for 1926, followed closely by local injuries, with an average constantly sick of 276.44 and 100,901 working days lost. Diseases of the digestive system, other than tonsillitis and diseases of the liver, come next, with 209.12 constantly sick and 76,329 working days lost. Abroad, except India, the order is the same. Venereal diseases show an average constantly sick of 298.50, with 103,952 days lost; local injuries 96.87 and 35,348 respectively; and diseases of the digestive system, other than tonsillitis and liver diseases, 90.84 and 33,157 respectively. The charts and tables will repay careful study.

#### Diseases of the Digestive System.

Dysentery accounted for 1,048 admissions, of which 892 were reported from India. Of these 892, 230 were diagnosed amoebic, 303 bacillary, and 359 group dysentery. The increase on the 1925 figures is largely balanced by a material reduction in the number of cases diagnosed colitis, which fell from 207 in 1925 to 45 in 1926. Particular attention must be drawn to the reduced incidence in Iraq, which was 7.1 per 1,000 in 1926 compared with 19.0 and 38.6 in previous years.

Enteric fever shows a decrease. Iraq had the highest incidence with 4.4 per 1,000, with India second with 2.7. An indication of the degree of protection afforded by inoculation in India is seen in the fact that the proportion of cases in the unprotected as compared with the protected was 7.7 to 1, and of deaths 10.4 to 1.

As in last year's report, diseases of the digestive system are dealt with at length, both medically and surgically, and the results of some investigations carried out at Aldershot and Woolwich are given.

The work of the special departments—medicine, surgery, hygiene, and pathology, together with an account of dental work among troops and the examination of recruits, form interesting reading in Section II of the report. The results of research and investigations should be helpful to those who are interested in the special subjects.

A summary of the measures adopted by the Government of India to combat malaria in military stations in India is included in Section III of the report, which gives detailed statistics and notes on the health of the troops in all commands at home and abroad, and of the women and children on the strength of the army.

## MEDICAL RESEARCH COUNCIL.

### ANNUAL REPORT.

(Concluded from page 234.)

#### II.

#### DISORDERS OF THE EXCRETORY SYSTEM.

At Gny's Hospital, London, Dr. A. A. Osman has continued his work on the prevention of nephritis after scarlet fever, and he has extended his method of giving alkalis to other forms of nephritis. Evidence has been obtained that alkalis, used prophylactically, can avert the onset of anuria under conditions in which this symptom commonly occurs, and that they can effectively protect the kidney and prevent nephritis following exposure to infection, metallic poisoning, bodily over-exertion, and poisoning with general anaesthetics. Dr. Dorothy S. Russell, under Professor Turnbull, at the London Hospital has been determining the correlations between clinical and chemical tests of renal efficiency, and the macroscopic and microscopic anatomy of the kidney. At Manchester Professor Shaw Dunn has been working with experimental nephritis, studying the changes produced in the tubular system of the kidney. Dr. S. L. Baker, at Middlesex Hospital, London, has also been investigating experimental nephritis.

#### DISORDERS OF THE NERVOUS SYSTEM.

Sir Charles Ballance's study of nerve suture at the National Institute has proceeded. Dr. M. Critchley has been working on cerebral arterio-sclerosis at the National Hospital, Queen Square, London. He is analysing the clinical syndromes usually spoken of as cerebro-vascular disease. Part of the work is concerned with the blood pressure variations in cerebral arterio-sclerosis examined with a view to eliciting points of prognostic value. Dr. J. A. McCluskie is continuing his research at Glasgow on disseminated sclerosis and neurosyphilis. He has recently

<sup>1</sup> Report on the Health of the Army for the Year 1926. Vol. LXII. London: H.M. Stationery Office. 1926. Price 3s. 6d. net.

directed his attention chiefly to the conditions required for the cultivation of spirochaetes. At the Royal Hospital, Sheffield, Professor Hall and others are studying the rigidity and slow movements as sequels of encephalitis lethargica. The nitrogenous metabolism, including the creatin excretion, has been followed up by Dr. Imrie and Miss M. Hirst in cases with marked rigidity.

#### Mental Disorders.

At Cambridge Miss L. G. Fildes continues her inquiry into the causes of mental defect in children, with special reference to the psychological nature of congenital auditory aphasia or word-deafness. Detailed study has also been made of certain abilities among the mentally defective, especially of their discriminative perception of size and of form. Dr. G. W. Pailthorpe is investigating mental conditions and criminal offences. She has examined psychologically one hundred cases in rescue homes, and spent a summer vacation in visiting prisons and rescue homes on the Continent. Dr. F. E. Reynolds, at the Scottish Asylums Research Laboratory, Edinburgh, has been exploring the paths of infection of the brain, meninges, and venous blood sinuses from neighbouring foci of inflammation.

#### THE GLANDS OF INTERNAL SECRETION.

At the Lister Institute, Professor V. Korenchewsky with Miss M. Schultess-Young, has been endeavouring to isolate the active principles of the testes and prostate. Results so far obtained indicate that active substances are present in both lipid and protein-like fractions of the sexual glands. Other work on the parathyroids seems to show that the parathyroid hormones and insulin are similar in their action upon nitrogen metabolism, and antagonistic to that of the thyroid gland. An investigation on the influence of parathyroid secretion on bone formation has been in progress at Newcastle-on-Tyne by Professor D. Burns and Mrs. Burns. Dr. A. S. Parkes and a group of workers at University College, London, have studied the internal secretions of the ovary; they suggest the hypothesis that there is an alternating dominance in the complete reproductive cycle of oestrus producer and oestrus inhibitor, each capable of being overridden in its naturally dominant phase by an artificial augmentation of the other. At St. Bartholomew's Hospital, London, Dr. Scott Williamson and Dr. Pearce have continued their work on Graves's disease. They believe there is a true secretion by way of lymphatic vessels which contains no iodine and is the intoxicative factor in Graves's disease, while the stored colloid material contains the iodine in thyroxine form.

#### Diabetes: Insulin: Synthalin.

Dr. G. A. Harrison has shown that inunctions of insulin are useless as substitutes for subcutaneous injections. Dr. R. D. Lawrence and Mr. R. A. McCance have been making a detailed investigation of the carbohydrate content of common foods, including an estimation of the pentose present. As a result of work with bacterial toxins in inhibiting the action of insulin in human beings and animals, it is suggested that this effect is due to the stimulation of the thyroid and adrenals. The clinical trials in several centres of the diguanidyl derivative known as synthalin have already been reported. Synthalin cannot be regarded as a substitute for insulin, but is thought to deserve further investigation.

#### TUBERCULOSIS.

Most of the work on this disease has been of a bacteriological or serological nature. Dr. A. S. Griffiths has been studying various problems at the field laboratories, Cambridge. He has shown that the bovine tubercle bacillus is the chief cause of tuberculosis in domestic mammals, being the only type of bacillus found in the horse, cat, and goat. The avian bacillus, however, has been found in many cases of localized tuberculosis in swine: in one hundred pigs supplied from Smithfield Market by Colonel T. Dunlop Young after being condemned as tuberculous, the avian bacillus has been found in more than 30 per cent. Dr. Griffiths has also studied the immunizing effect of Calmette's "B.C.G." vaccine when given by the mouth,

and the results so far do not confirm the conclusion of Calmette that susceptible animals can be protected against infection with virulent tubercle bacilli by feeding with "B.C.G." Professor S. L. Cummins has continued his studies of sanocrysin in the treatment of selected cases and further experiments. By careful selection of patients the results gained with sanocrysin appear to justify the hopes Professor Cummins formed of it during his initial tests in 1925. Dr. R. G. Bannerman, at the Cripples' Hospital, Alton, has confirmed Sir Almroth Wright's work that the tubercle bacillus grows more luxuriantly in normal plasma than in that of tuberculous patients. He has also improved upon the usual method of performing the "sedimentation" reaction. The Tuberculin Committee has been active, continuing to advise the Ministry of Health upon the tests to be exacted for herds producing graded milk. Most of the committee's work is given to the examination of particular forms of tuberculin advocated for the treatment of tuberculosis in man. In no instance, so far, have these new varieties of tuberculin been found to have any advantages over the tuberculins already in use by the profession.

#### CELL AND TISSUE GROWTH.

The investigations at the Research Hospital, Cambridge, are being extended under the general management of Dr. J. A. Andrews, acting in the place of the late Dr. T. S. P. Strangeways. The direct and indirect effects of  $\alpha$  rays upon chick embryos of various ages have been studied. It was found that 20 to 25-hour embryos, in which blood circulation was not yet established, can recover from the effects of  $\alpha$  rays, while embryos 6 to 17 days old, with their active circulation, cannot recover after similar treatment. It has been shown that the death of the older irradiated embryos is due to the inhibition of gaseous exchange due to action of the rays on the circulatory system itself. At the same place Dr. R. G. Canti and Dr. F. G. Sparc have investigated the effects of irradiation of "gamma" rays on cell division in tissue cultures. The biochemistry of tissue growth has been studied under the direction of Sir Frederick G. Hopkins. Mrs. B. E. Holmes and Miss E. Watchorn have continued their work on growing kidney tissue, and the production of urea and ammonia, already studied, it is now suggested is due to protein breakdown, by means of which the growing tissue provides itself with energy for growth. Other studies have been made of nitrogen exchange in the tissues of the brain.

#### MALIGNANT DISEASE AND RADIATION.

At the Middlesex Hospital, London, Dr. Helen Chambers has proceeded with her investigations of the substances in inoculated tumours which influence tumour growth. She has been especially tracing the properties of the substance stimulating growth and the conditions under which it is formed or may be extracted and isolated. It is not a living agent, as it is formed under conditions in which bacteria cannot grow. The Council has a supply of radium entrusted to it by the Government, and distributed to five hospitals in London and four institutions elsewhere. Radium emanation derived from the portion of this element at Middlesex Hospital is available for the general scheme of treatment of malignant disease directed by the Radiology Committee, the expenses of the supply being largely borne by the British Empire Cancer Campaign. At University College, Bangor, Professor E. A. Owen is investigating the effect of  $\alpha$  rays of different wave-lengths upon living tissues and bacteria. Dr. H. A. Colwell, at King's College Hospital, London, is studying the physiological actions of secondary radiations.

#### CHEMOTHERAPY.

The Department of Scientific and Industrial Research and the Medical Research Council have appointed a committee to draw up a scheme for joint work on this subject. Mention is made of the preparation of new organic compounds at Leeds by Professor J. B. Cohen, F.R.S., and their biological examination at Glasgow by Professor C. H. Browning. A special study has been made of trypanosome infections; aminostyrylquinoline and amino-anilquinoline compounds are found to show promising

trypanocidal properties in experimental infectious. It is found in general that such substances appear to act by first killing some of the parasites, and thereby an immunity response is produced, leading to destruction of the rest.

#### GENERAL BIOCHEMICAL RESEARCHES.

##### *Bacterial Chemistry.*

At Cambridge Miss Stephenson has correlated the enzymic activity of bacterial suspensions with the numbers of living and dead organisms present. Further work on the dietary requirements of strict anaerobes has been continued, but has not led to the discovery of an adequate synthetic medium. Continued investigation of enzyme action by Mr. Woolridge and Dr. J. H. Quastel has resulted in the development of some striking new views of the mechanism of enzyme action connected with surface structure. At Leeds Professor J. W. McLeod is examining the propionic acid bacteria which have been described as anaerobes capable of producing catalase.

##### *Colloids.*

At Cambridge Dr. C. G. L. Wolf, with others, is proceeding with his consideration of the physico-chemistry of precipitin reactions. With Dr. G. S. Haynes he has completed the first part of a study of the diagnosis of cancer, using the interferometer for the detection of digestion of specific substrates. It has been shown that this method fails to reveal any digestion, and the colloidal changes taking place are entirely unrelated to any diagnostic significance.

##### *Metabolism.*

Dr. T. Izod Bennett, with Dr. D. T. Davies and Professor E. C. Dodds, has studied the significance of excess of cholesterol in the blood in various pathological conditions. Nephritis with oedema has been especially considered in this respect. At Cambridge Mr. A. Carruthers has investigated the resynthesis of glycogen from lactic acid under the influence of oxygen by tissues other than muscle. He has been unable to confirm Meyerhoff's observation that liver tissue can synthesize lactic acid to glycogen. At Cardiff Dr. J. Pryde and Mr. J. M. Peterson have studied the unknown sugar-phosphate component of animal nucleic acid. This has been isolated, and detailed investigation is being made by the wave-length spectrometer of the striking colour reactions given by this compound and the parent nucleic acid.

##### *Anaesthetics.*

Many points of general scientific interest, and of especial interest in regard to its anaesthetic action, have been revealed by examination of the impurities likely to occur in nitrous oxide by Mr. A. N. C. Bennett at University College, London. Professor H. B. Dixon, F.R.S., at Manchester, has been investigating the ignition points of various anaesthetic agents. He has found that both ethylene and propylene burn in nitrous oxide and form highly explosive gas mixtures. The Anaesthetic Committee has been collecting information about "ether convulsions." No adequate explanation of some of the fatalities associated with these phenomena has yet been reached.

#### GENERAL PHYSIOLOGICAL AND PATHOLOGICAL RESEARCHES.

Mr. P. Eggleton, under Professor A. V. Hill, F.R.S., in London and at the Marine Biological Laboratories, Plymouth, has continued his study of the substance "phosphagen," a constituent of muscle he discovered in 1926. He has shown that phosphagen breaks down in a muscle in contraction and is resynthesized during the recovery process in the presence of oxygen. It has also been shown that phosphagen is apparently connected with the velocity of contraction. Work on immunity by Sir Almroth Wright has proceeded during the year. New experiments have been made on the "interaction" occurring between fluids of different kinds in contact. Dr. Colebrook, with Dr. Hare and Dr. Roche Lynch, has been investigating compounds of the novarsenobenzol type and their use in the treatment of puerperal fever and other streptococcal infections. By using those found least toxic, and by spacing the doses so as to maintain adequate concentration in the blood, it is possible to prolong considerably the acquired potency of the blood

in its defence against streptococci. "Mercurochrome" has been found not to confer bactericidal power in animals, either upon the blood or bile. At the London Hospital Dr. P. G. Fildes and Miss A. Greaves have continued work on tetanus and the mechanism of immunity against tetanus infection. It has been shown by direct experimental evidence that the immunity is due to the high oxygen tension of the tissues themselves preventing germination of the spores, except in areas in which tissue damage has caused a local asphyxia. Dr. L. S. P. Davidson, at Edinburgh, has devised a method for quantitative estimation of the chief groups of intestinal bacteria by which the differences of intestinal flora in health and disease can be shown and tabulated numerically. In cases of pernicious anaemia he has found a very suggestive high count of *B. welchii*. Dr. Katherine J. Guthrie has continued the study of enteric carriers at Glasgow. A chronic urinary excretor of *B. typhosus* has been especially investigated, and treatment with a vaccine of thermostabile antigens of *B. typhosus* has been begun.

##### *Vision.*

Three groups of work have been in progress on the physiology of vision. Problems of the fighting services calling for investigation have been attacked, such as the visual factors determining proficiency in gunnery and the visual factors which distinguish a man who may become a good rifle shot from one who will never shoot well, where the results obtained by Dr. H. Banister at Cambridge seem to indicate that visual acuity is of less importance than might be expected. A second category of work has been concerned with glare and flicker. Dr. D. N. Buchanan has investigated the effects of continuous exposure to flickering light over a period of months. With the assistance of Mrs. W. H. Corkill at University College, London, Dr. R. J. Lythgoe has studied the rates of eye movement in different directions, with and without glaring sources of light in the field of vision, which is a contribution to some urgent practical problems of motor driving at night. The third group of investigations is concerned with the physiology of reading. Study of the effects upon vision of industrial occupations involving the risk of eye-strain has been continued by Dr. Duke-Elder at the London School of Printing in co-operation with the principal, Mr. J. R. Riddell.

#### INDUSTRIAL MEDICINE AND INDUSTRIAL FATIGUE.

Work on dust inhalation and pulmonary disease has been continued at Oxford by Dr. J. S. Haldane. Haemattite has been found to produce reactions not definitely harmful, while it has been established that soluble silica is the most deadly of all dusts as yet examined. Further inquiry is being made into the pulmonary effects of the fineness of the state of division, of the amount of dust inhaled, and of its solubility. Outbreaks of jaundice, apparently infective in nature, have been investigated in Scotland by Professor T. J. Mackie and Dr. D. G. S. McLachlan in regard to the question of spirochaetal jaundice in mines. Conclusive proof of the nature of these mild cases, mostly in children, was not obtained, but in two of the outbreaks studied the evidence suggested a spirochaetal origin. The work of the Industrial Fatigue Research Board has been described in the annual report of the Board, published separately by the Council, and a summary only of the progress of the statistical committee, the committee on the physiology of muscular work, the committee on industrial psychology, and other general industrial investigations is given.

##### *CONCLUDING NOTES.*

There is a short section in the Council's report dealing with the Travelling Fellowships. A summary of the investigations of last year's Fellows is given, together with a list of the awards for the academic year 1927-28. The changes in the membership of the Council are noted, and the heavy losses sustained during the year by the deaths of Dr. John Brownlee, director of the statistical department since 1914, Dr. T. S. P. Strangeways, and Professor E. H. Starling, are mentioned with sympathetic reference to the inspiring work of these three investigators in different branches of medical research.

# British Medical Journal.

SATURDAY, FEBRUARY 18TH, 1928.

## JOHN HUNTER.

ONE hundred and eighty years ago a raw lad of twenty came from the South-west of Scotland to London, just as his friend of after years, Tobias Smollett, had done nine years earlier. Both of them were destined for the medical profession, wherein the younger was to achieve a name and a fame which seem likely to endure at least as long as the English language and the study of biology.

The other failed to distinguish himself in medicine, but turned to literature instead, and before he died Tobias Smollett desired that his body should be given to John Hunter for dissection.

Hunter, of whose birth the bicentenary was celebrated this week on St. Valentine's Day, left Long Calderwood, his birthplace, without having shown any of the qualities which afterwards so eminently distinguished him. His education had been imperfect and irregular, and perhaps not the least valuable part of it had been an apprenticeship to a cabinet-maker, which must have helped to teach the future experimental philosopher the use of his fingers. His career in London has been recorded and commented upon in the many orations which have been delivered at the Royal College of Surgeons and elsewhere since his death in 1793. His achievements are well known, and some reminder of them is given in the early part of Sir Holburt Waring's interesting Hunterian Oration, with which our present issue opens. Yet it may be permitted to us once more to try to bring before our readers some conception of the man and his manners and surroundings, and of what his name stands for in science to-day.

Some men, like William Harvey, have been celebrated in their lifetime among the few whose knowledge enabled them to appreciate great scientific discoveries and the qualities that lead to their making, but have not been known to the larger public. John Hunter enjoyed both kinds of fame. He became a Fellow of the Royal Society before he was forty, he received its Copley Medal, which is the greatest honour it has to bestow, he was surgeon extraordinary to the King, and held the highest rank in the medical department of the army. Besides all this, he had the confidence of the profession and of the public, which brought to him what for those days was a very lucrative practice and a large income, which enabled him to indulge fully the great passion of his life—namely, the collection and investigation of all sorts of living animals and of their bodies after death. More wonderful than all, his fame was such that after his death the House of Commons, little accustomed to taking an interest in science or to vote money

for the furtherance of scientific purposes, actually allowed itself to be induced to purchase his collections for the nation at a cost of £42,500, at a time when money was sorely needed for powder and shot. Surely an enviable career! Yet there was another side to the picture. For the last twenty years of his life he carried on a losing fight with a disease which caused him great suffering, and which, as Sir D'Arcy Power has shown, was almost certainly the result of a scientific experiment carried out upon himself with the hope of ascertaining the relationship of syphilis and gonorrhoea. Despite what he considered to be a sufficient course of mercurial treatment, he remained a subject of infection by the venereal parasite, which killed him in the end, in the ante-chamber to the board room of St. George's Hospital. He must have suffered much in those later years; and that he knew how precarious was his condition is shown by his remark that his life was in the hands of any rascal who chose to annoy and tease him. In fact, a difference of opinion with his colleagues proved enough to snap the frail thread of his life.

The question naturally suggests itself, What were the qualities and attainments which procured for Hunter this remarkable reputation and position in the public eye? It was certainly not by the arts of the courtier that he succeeded, for as one of the greatest of Hunterian orators, Sir James Paget, has said: "He was a rough and simple-minded man, abrupt and plain in speech . . . quickly ablaze with anger and fierce word, never personally attractive or seeming to have great mental powers, and always far too busy to think of influencing those around him. He had few friends, he gained the personal regard of very few, and no one ever paid him the homage of mimicry. The vast influence which he exercised on surgeons was the outcome of the scientific mind." Yet those who knew John Hunter best entertained the warmest feelings of regard for him. To Edward Jenner, who had been his resident pupil, and to a number of other disciples he was always "The Dear Man." The younger surgeons of his later years who became the leaders in surgery in the first quarter of the nineteenth century were his pupils and admirers. Among them were Abernethy, Astley Cooper, Blizard, Clive, and Carlisle. These men, and others, handed on the torch of surgical pathology and Hunterian principles to the next generation of surgeons.

His portraits (of which Sir Arthur Keith gave so attractive an account in our last issue) do not suggest such a man as Paget describes, hot tempered and unreasoning in his anger. From them alone one would draw a mental picture of a thoughtful, even dreamy personality, genial and pleasant. This is particularly true of the great picture by Reynolds, of the painting of which we are told that the artist caught him in a kind of reverie, and there and then fixed his pose and expression on the canvas. Must not the ill health of his later years, accompanied or caused by degeneration, not only of the coronary but in a marked degree of the cerebral arteries, have been responsible for such lack of equability as he may have displayed? It is one of the tragedies of medical history that Hunter should have so disastrously impaired his health and thereby the usefulness of the last years of his life, and besides have probably shortened that life, by an experiment which was fruitless, except in so far as it was misleading. With our fuller knowledge we see that he infected himself, not from a case of simple gonorrhoea, but from one of mixed infection, and that he suffered from the remote results of true syphilis, as he himself

knew, but that the inference he drew that gonorrhoea and syphilis were one was false, resting as it did on a false premiss.

John Hunter took a teleological view of the history of living things, assigning to Nature the role of Providence, which made provision for the needs of every organism; but when he came to the study of fossils his penetration convinced him that such processes and changes as he observed or inferred must have taken up more than the six thousand years which were all that the accepted chronology of Bishop Usher allowed for the age of the world on the basis of Bible chronology. This unorthodox view was expressed in his "Observations and reflections on geology," which he had intended to contribute to the Royal Society, but refrained on the advice of a friend, lest his heterodoxy should give offence. Books had little attraction for him, except the great Book of Nature, which he studied both closely and fruitfully. Indeed, he had little knowledge of the science of his day, of chemistry or optics or physics in general, and this ignorance of so much that so often forms an important part of the equipment of men of great intellectual distinction makes almost irresistible the conclusion that Hunter's achievements were the outcome of true genius.

### THE WASSERMANN REACTION IN PREGNANCY.

In the Winter Number of the *Journal of Obstetrics and Gynaecology of the British Empire* Dr. Gladys H. Dodds' records and analyses the results obtained by the performance of the Wassermann test on 2,000 consecutive pregnant women in the Obstetrical Unit of University College Hospital Medical School. The purpose of this inquiry was to estimate the value of the routine use of the Wassermann test at ante-natal clinics. It has sometimes been questioned whether the results of the Wassermann test are as much to be relied on during pregnancy as in the non-pregnant subject. From investigations made in Edinburgh on 100 women suffering from syphilis F. J. Browne concluded that pregnancy has little or no influence in modifying the Wassermann reaction. Similarly, Boas, Gammeltoft, and Siecke, investigating response to the test in 2,200 pregnant women in Scandinavia, with 6.7 per cent. of positive results, concluded that the Wassermann reaction was as trustworthy during pregnancy and childbirth as at other times.

On the strength of the Wassermann report Dr. Dodds divides her cases into six groups, which may be termed the strongly positive, positive, weakly positive, doubtful, anti-complementary, and negative, respectively. Of the 73 women with the strongly positive reactions either a history of syphilitic infection or clinical manifestations were obtained in 47. In 17 women with no history or manifestations of syphilis there was a repeated Wassermann reaction, in some a suggestive obstetric history, and the babies of four showed syphilitic manifestations. Six patients had a positive Wassermann reaction as the only sign. Of the six cases with a positive reaction, the diagnosis was established in four, but the remaining two gave no history of infection and showed no specific manifestations. It was in this group that the value of the routine use of the Wassermann test was most

clearly indicated. The third group with weakly positive reactions is considered by Dr. Dodds to be the most interesting, since most clinicians are reluctant to attach importance to a reaction unless it is strongly positive; they fear a wrong diagnosis and do not wish to label their patients as syphilitic. Clinical manifestations were found in six out of nineteen cases in this group, which justifies a more careful consideration of these cases. Again, syphilis in pregnant women is often latent. Summarizing the cases with weak positive reactions, there were 30 in which this finding was obtained at the first examination. In one a triple positive was obtained after a provocative injection of an arsenical compound, and six were again negative after a provocative injection. In ten cases the reaction was weakly positive more than once—in four even after a provocative dose. In one case the reaction became doubtfully positive after such a dose. Nine cases were insufficiently investigated. Dr. Dodds considers that these findings justify us in regarding the weak positive reaction with suspicion of syphilis. In 17 cases the reaction was a doubtful positive, and 12 were still negative after a provocative injection. Five were not further investigated. No history of infection and no clinical manifestations of syphilis were found in any of the cases investigated. Dr. Dodds accordingly does not regard the doubtful positive results of any significance. Six cases were reported to have anti-complementary serums, a condition stated to be more frequent in pregnancy than at other times. These cases presented no clinical significance. There were 15 cases with a negative reaction which presented clinical evidence of syphilis.

There can, therefore, be little doubt as to the value of the application of the Wassermann test as a routine procedure in pregnancy. Dr. Dodds points out that in the Obstetrical Unit at University College Hospital the urine of the pregnant woman is examined for albumin as a routine, and silver nitrate is always instilled into the eyes of the newborn infant, and that many tragedies are thereby averted; she contends that many more could be averted by the routine examination of the blood, with the additional aid of a provocative dose of one of the arsenical compounds, if necessary. She insists also on the need for a fuller investigation and "following up" of cases in which an incomplete Wassermann reaction is obtained.

### ANTIRACHITIC EFFECT OF SUNSHINE.

In a paper by Drs. Alan Brown and Frederick F. Tisdall on the seasonal variation of the antirachitic action of sunshine and its effect on resistance to disease, in the *Canadian Medical Association Journal* for December, 1927, it is remarked that study of the literature dealing with the etiology of rickets shows how little has been discovered in this regard from the time of Glisson until the past ten years. It remained for Mellanby in 1918 to demonstrate the presence of a substance which possessed antirachitic properties and was effective in the prevention of rickets. It was at first uncertain whether this substance was something other than vitamin A, but this was definitely established by McCollum and his co-workers, who distinguished it by the name of vitamin D. Cod-liver oil is now recognized as its most concentrated source. Huldshinsky, in 1919, was the first to demonstrate the curative action of ultra-violet light in rickets; he employed the rays emanating from a mercury vapour quartz lamp. His results have since been abundantly confirmed by many workers. In 1921 it was shown by Hess and Meyer that a similar effect could also be obtained by exposure to the

<sup>1</sup> An Analysis of the Results of the Wassermann Reaction obtained from 2,000 Consecutive Pregnant Women. Gladys H. Dodds, M.D., D.P.H. *Journ. Obstet. and Gynaecol. of the British Empire*, Winter Number, 1927, pp. 273-287.

direct rays of the sun, and this was confirmed experimentally on animals by Park and Hess. Then Rosenheim and Webster in England, Hess, Weinstock and Helman, and Steenhock and Black in the United States, working independently, found that food containing cholesterol and allied substances acquired antirachitic properties on being exposed to ultra-violet rays. More recent investigations, however, have shown that the substance concerned is ergosterol, which is usually present as an impurity in cholesterol in the proportion of 1 in 2,000 parts. Brown and Tisdall give some indication of the great potency of activated ergosterol when they state that the administration daily of 1/10,000 mg. of it to a rat on a rachitogenic diet cures or prevents the disease, and that 5 mg. of it produce the same antirachitic effect as one litre of active cod-liver oil. The curative results of exposure to the rays, either from an ultra-violet lamp or from the sun, are due to certain rays present in the ultra-violet portion of the spectrum, experimental work with cholesterol showing that the maximum antirachitic potency is possessed by rays of 302 millimicrons in wave-length; the most effective rays of the sun, both for the prevention and the cure of rickets, are those which range from 290 to 313 millimicrons. Unfortunately, these short wave-lengths have very feeble penetrating powers, and are thus readily cut off by the smoke, dust, and moisture of the atmosphere; they are thus markedly reduced in winter, and also in the early morning and the late afternoon, when they have to pass through a thicker layer of the atmosphere than at noon, when the sun is high in the heavens. Thus Brown and Tisdall found that the sun's rays in December, January, and February, in the latitude of the city of Toronto, produce a slight but definite antirachitic effect on rats fed on a rachitogenic diet; a very sharp increase occurs in the antirachitic effect of sunshine about March 1st, while the antirachitic effect of April and May sunshine is approximately eight times as great as that of December, January, and February. Further, the antirachitic effect of skylight (reflected rays from the sky and clouds) is about one-half to two-thirds of that produced by sunshine (rays from the sun *plus* the reflected rays from the sky). It should be noted that reddening of the skin is not a suitable unit for the measurement of ultra-violet therapy; it should merely be considered as an accompanying phenomenon. Sunshine which has passed through special glass, such as corning glass, vitaglass, or vioray, has from 20 to 25 per cent. of the antirachitic effect obtained without the use of such glass; hence the employment of this glass is justified when inclement weather prevents the direct exposure of patients to sunshine so as to obtain the benefit of its antirachitic properties. Again, experimental data were obtained which show that sunshine definitely increases the resistance of albino rats to infection with specific micro-organisms, and there can be little doubt that the same effect would also be derived from it by the human subject. Lastly, exposure to sunshine was found to increase the acidity of the intestinal tract of exposed rachitic rats, and Brown and Tisdall claim this as additional evidence that the sun's rays definitely aid in digestion.

#### THE DOSAGE OF PITUITARY EXTRACT.

THE labelling clauses of the Therapeutic Substances Act, which have just come into force, enact that all pituitary extract is to be labelled in respect of its content of physiological units. The strength of pituitary extract will therefore henceforward be measured by a uniform international standard, and this should permit the dosage of the drug to be defined with considerably greater accuracy than has hitherto been possible. This problem of dosage deserves careful consideration, because in the past there has been

a considerable variation in the strength of pituitary preparations. The general tendency of such variations has been to encourage overdosage of pituitary extract, because failure of the drug to produce an effect is bound to cause delay and may involve danger in childbirth, and hence obstetricians have tended to choose a dose which would be certain to be effective, even though the sample used were considerably below standard. Bourne and Burn<sup>1</sup> have recently published a very careful analysis of the action of pituitary extract. Their findings are based on graphic records of the uterine movements during parturition. Their chief conclusions are as follows: "A dose of two units may be expected to produce an effect which should be useful in hastening the course of a sluggish labour, provided that it is not administered before the os is about one-half dilated. A dose of two units may be given with safety at any stage, provided there is no mechanical obstruction. The least interval at which any dose can be usefully repeated is one hour, but often the effect of two units has lasted longer than this." They mention that a dose of two units in some patients "produced a very striking increase in uterine action, as large, indeed, as it would seem advisable for an increase ever to be." The usual concentration of pituitary extract is ten units per cubic centimetre, and doses of one-half or even one cubic centimetre of the extract hitherto have been in common use. The results of this inquiry indicate, therefore, that the dosage hitherto employed should be reduced considerably. The conclusions regarding the dosage of pituitary extract in labour confirm those reached by other workers.

#### SEPULCHRAL STATISTICS.

THE day has long gone by when for the majority of the inhabitants of these islands their last resting place is the quiet village churchyard beloved of the poets. Some few there are still, almost exclusively among the land-owning classes and the fast dwindling rural population, who may view the prospect of sleeping their last long sleep beneath the shadow of the old yew tree; but for the mass of urban dwellers, if they think about the subject at all, their thoughts must perforce turn towards some huge cemetery, where the headstones are crowded together in almost indecent proximity, and the surroundings, as likely as not, are gasworks or main lines of railway. Unless the actual figures are presented it is almost impossible for the ordinary individual to conceive the amount of ground required and the cost involved in making provision for the 600,000 interments which take place annually. These details have recently been published by the Cremation Society of England in a pamphlet entitled "Cemeteries in England and Wales—Statistics to 31st March, 1926, of Municipal Undertakings."<sup>2</sup> The society has gathered together the figures relating to 335 cemeteries, owned and managed by 166 municipalities acting as burial authorities for their respective areas. This is said to be the most complete return of the kind issued in recent years. The population covered by the survey is estimated at 17,528,548 persons, and the average number of interments per annum is 173,073. The area of land occupied or reserved for cemeteries is over 8,400 acres, or 12½ square miles, and the total expenditure on purchasing land or laying out burying grounds exceeds five million pounds. Assuming that these statistics cover about half the population of England and Wales, we arrive at the staggering conclusion that 16,000 acres, or 25 square miles, are set apart for no other purpose than burying the dead—an area which, otherwise employed, would have housed half a million people, with a consequent increase of rateable

<sup>1</sup> The Dosage and Action of Pituitary Extract, etc., *Journ. Obstet. and Gynaecol. of the British Empire*, 249, 34, 1927.

<sup>2</sup> Copies from Mr. Geo. A. Noble, 52, New Cavendish Street, London, W.1. or Mr. A. E. Piggott, 56, Mosley Street, Manchester. 2s. post free.

value, or would have served the purpose of providing the sorely needed space for playing fields. Between November, 1918, and April, 1926, local authorities were granted permission by the Ministry of Health to borrow £1,249,905 solely for the provision of land for new cemeteries or the extension of old ones. The unproductive nature of this vast expenditure is proved by the authors of the pamphlet when they demonstrate that the annual cost to the rates amounts to about £162,000. In the case of twenty-eight authorities there is an average gain of 11s. 5d. per interment, but in the case of the remaining 138 there is an average loss of £1 6s. per interment. The loss, as might be expected, varies much in different boroughs, being as a rule heaviest in the more populous manufacturing areas. These figures are not mere guesswork, but have been accurately compiled from statistics furnished by the local authorities themselves, and they have been set out in a series of schedules showing the particulars for each locality in full detail. No more convincing argument for the general adoption of cremation as the only reasonable means of disposing of the dead in an overcrowded country has ever been published. The facts presented are really so obvious that they speak for themselves. One of the chief arguments against cremation has been that the cost is higher than that of burial. A careful analysis of the figures on an actuarial basis shows that the total cost of each interment works out at £4 12s. 6d., whereas the average cost in about 3,000 cremations is £6 6s. In this connexion the society asserts, with every show of truth, that if the number of cremations were increased to only 10 per cent. of the total number of deaths, the cost could be reduced to very much below the cost of burial, while the gain to the community in acreage alone, occurring as it would in areas where space is most needed, would be enormous.

#### CHOLERA BILIVACCIN.

Most vaccines are introduced into the system by puncture of the skin. The wound, though trivial, is to some extent a deterrent, especially among primitive peoples who are strange to the ways of modern therapy, and who may in addition have personal scruples from which more sophisticated races are free. The question, therefore, of employing the more familiar oral route for the administration of vaccines is one of considerable practical importance, but in the case of any particular vaccine it will necessarily turn on the relative efficacy of vaccination *per os* and vaccination *per cutem* as tested by experiment. The rival claims of cholera bilivaccine given by the mouth, as advocated by Besredka, and commercial anticholera vaccine given subcutaneously furnish a case in point. Otton and Kirschnner have maintained that Besredka has wholly failed to prove that the results of cholera vaccination by the mouth are better than, or even as good as, those of subcutaneous vaccination; while Dietrich, also opposing Besredka's views, casts doubts on the possibility of cholera vaccination by the mouth producing any results at all. Light has recently been thrown on this question by experimental field work carried out in the Presidency of Madras at the instigation of the Public Health Commissioner with the Government of India, and now reported, in a print issued under the authority of the Health Organization of the League of Nations, by Colonel A. J. H. Russell, I.M.S., Director of Public Health of the Presidency. The observations were made during the winter cholera epidemics of 1925-26 and 1926-27. The total number of persons observed was 71,979, all resident in areas rarely free from cholera. Of this total 17,080 were observed in respect of the oral bilivaccine, 6,076 receiving doses ranging from one to three and 11,004 being controls; while 54,899 were observed in respect of the subcutaneous anticholera vaccine, 25,645 receiving one or two doses and 29,254 being controls.

Among persons taking the full course the attacks of cholera were for the bilivaccine inoculated 0.36 per cent., for the anticholera vaccine inoculated 0.37 per cent. Among controls the attacks of cholera were for bilivaccine 2.02 per cent., and for anticholera vaccine 1.67 per cent. Every precaution appears to have been taken, subject to the limitations inseparable from field work, to ensure the accuracy of the original data and the comparability of groups. In the statistical analysis the methods of determining the coefficients of correlation and the checks applied are stated in detail. The resulting figures are set forth under eleven heads and their significance deduced. Colonel Russell's final conclusions are quoted: "It may therefore be inferred that, remembering the limitations already mentioned, a high degree of immunity is conferred by the administration of the oral and subcutaneous vaccines, but that the effect of the anticholera inoculation is, in the long run, superior to bilivaccine treatment. In view of the fact that risk of injury resulting from inoculation is inappreciable, and that even transitory discomfort is uncommon, the case in favour of anticholera vaccination as a practical measure is complete."

#### THE CYTOLOGY OF JENSEN'S RAT SARCOMA.

ONE great advantage of tissue culture as a histological technique compared with the examination of tissues by means of sections of fixed material lies in the fact that in cultures *in vitro* the individual cells can be isolated, and their cytological characters, amoeboid and intracellular movements, mitoses, and degenerative changes can be studied in the living condition. The application of the tissue culture method to Jensen's rat sarcoma has enabled H. B. Fell and J. A. Andrews<sup>1</sup> to distinguish two types of cell within this tumour, one resembling fibroblasts and the other wandering tissue cells. At first sight this seems opposed to orthodox views about sarcomas, for, although considerable variability in size, shape, and staining is a feature of a sarcoma, it has usually been assumed that the differing appearances represent only varying phases in the development or morphology of one type of malignant cell. From the application of tissue culture methods, however, convincing evidence is now offered that at least two histologically distinct classes of tissue are present in this sarcoma—fibroblast-like cells and lymphoid cells, the cells differing both in morphology and behaviour. The fibroblast cells are spindle-shaped or triangular, and generally larger than the other type of cell, referred to as lymphoid or "wandering cells." These wandering cells sometimes assume a complex arborescent shape reminiscent of the nerve cell with its dendrites; they often contain fat globules and granules, and if solid carmine is added to the medium in which the cells are cultivated these granules are beautifully stained *intra vitam*, as the author's good illustrations show. The cells differ considerably in their movements. The fibroblast cells, when observed at body temperature, are seen to be in slow but constant movement. The outline of the cell is gradually but continually changing. Large elongated or wedge-shaped pseudopodia are very slowly protruded and may be suddenly withdrawn, leaving behind numerous long needle-like processes of cytoplasm, which are eventually retracted into the cell body. The cell may gradually expand or contract, and small variations in contour are continually seen. Within the cell, especially in the pseudopodia, the cell organs show considerable motility. The long filamentous mitochondria pass slowly to and fro, twisting and bending and sometimes breaking into two, while the smaller rod-like forms move rather more rapidly. In contrast with these fibroblast-like elements the wandering cells are much more actively motile, and in a serum and plasma medium are usually the first to

<sup>1</sup> Brit. Journ. of Exper. Path., vol. viii, p. 413.

crawl out from the explant. Pseudopodia are thrown out, with surprising rapidity, glide, swell, and are withdrawn as quickly, to start anew from a fresh site in the surface of the cytoplasm. The nucleus is often correspondingly distorted, and lobes, sometimes showing a marked constriction, bulge into the bases of the main pseudopodial branches, only to be drawn back into the main body of the nucleus as the pseudopodia are retracted. The authors describe graphically how the restless turmoil of the cell is enhanced by the violent activity of the cytoplasmic inclusions. Mitochondria, small fat globules, and cell granules scour to and fro along the pseudopodia, jostling one another, and showing at the same time a ceaseless dancing motion resembling Brownian movement. These differences in form and behaviour are paralleled also by apparent differences in function. The wandering cells, which are more actively phagocytic than the fibroblasts, are thought to be of lymphoid character, for by dark-ground illumination they are indistinguishable in structure and behaviour from the wandering cells of normal embryonic tissue cultivated *in vitro*, or from the larger lymphoid cells in cultures of adult spleen. On the other hand, the fibroblast-like cells are similar to embryonic connective tissue cells, and their main function is to provide scaffolding for other tissues. Since there is no histogenetic relation between these two cells the question arises as to which of the two types of cells is the malignant agent. For the Rous sarcoma of the fowl Carrel has adduced experimental evidence that lymphoid elements—so-called monocytes—are responsible for the malignancy of this tumour. By analogy it is possible to deduce that the wandering cells may be the malignant components of the rat sarcoma, while the fibroblast-like cells represent stromal elements, but such a hypothesis could only be verified by further experimental work.

#### WHEELS AND BITES.

ALTHOUGH the bite of a blood-sucking insect and the resulting wheal, with its often intense itching, are so well known, surprisingly little has been really understood about this skin reaction, and especially its purpose in relation to the transmission of the parasites of which the insect is the carrier. Many years ago it was suggested that the salivary secretion of mosquitos, which (among other insects) produce this skin reaction, had as its function the prevention of clotting of the blood on its way to the stomach; subsequent work throw doubt on this hypothesis. In 1914, however, Cornwall and Patton were able to demonstrate the presence of an anticoagulin in the salivary glands of various blood-sucking arthropods, and, in some cases at least, a neutralizing coagulant enzyme existed in the stomach. A recent letter to *Nature* (January 7th, p. 13) by Dr. Lloyd of the Tsetse Investigation in Nigeria helps to throw some light on this interesting problem. Dr. H. M. O. Lester, he recalls, has established that tsetse flies have both an anticoagulin in the secretion of the salivary glands and a coagulin in the secretion of the digestive tract. *In vitro* experiments demonstrate that their action on the blood is very like that of antikinase and kinaso respectively. (In the leech, which, of course, belongs to a different zoological group, the anticoagulin—the so-called hirudin—is an antithrombin.) The old hypothesis has therefore been revived, and the members of the Tsetse Investigation have performed some ingenious experiments to show its validity. The entire salivary glands have been removed from flies—a delicate operation, which, however, can be carried out without causing the tsetse any appreciable shock. Flies thus treated feed normally for a time, but cause no wheal whatever on even the most sensitive skin. They live for quite long periods—up to two months—producing normal larvae and behaving in a normal way. Sooner or later,

however, the insect chokes or shows symptoms of convulsions and cannot feed. Dissections show that the lumen of the gut has become closed by a blood clot. Further experiments indicate that the amount of salivary secretion mixed with blood prevents its coagulation for several hours, but the secretion of coagulin is so powerful that it is neutralized in a few seconds and a clot formed, which is then in a position to be digested. In this fly, therefore, the production of the skin reaction is purely an accident, although often a painful and sometimes a dangerous one. The salivary secretion mixes with the blood at the very tip of the proboscis, and a certain amount always escapes into the skin of the host. Dr. Lloyd and his colleagues have thus solved an interesting problem with important practical bearings.

#### ROYAL COLLEGE OF PHYSICIANS.

THE Royal College of Physicians of London is celebrating on May 14th next and following days the tercentenary of the publication of William Harvey's book *De Motu Cordis*, an event that laid the foundation stone of modern physiology and scientific medicine. Delegates and distinguished guests from all parts of the world have been invited to participate in an interesting programme of scientific and social gatherings. The College is reviving on this occasion an honour that has been bestowed but seldom in the four centuries of its existence by electing to its Honorary Fellowship the Earl of Balfour, Sir Ernest Rutherford, and Professors Ivan Petrovitch Pavlov and Karl Friedrich Wenckebach, each of whom has rendered signal service, directly or indirectly, to the advancement of medical science. The spring lectures at the College open on March 1st, when Dr. F. A. E. Crew will give the first of his three Milroy Lectures on "Individual, familial, and racial differences in respect of immunities and disease resistance"; the second and third lectures will be delivered on March 6th and 8th. Dr. Izod Bennett will give three Goulstonian Lectures on "Some problems of nephritis" on March 13th, 15th, and 20th. The Lumleian Lectures on "Epilepsy" will be given by Dr. James Collier on March 22nd, 27th, and 29th. Dr. E. P. Poulton will give the Oliver-Sharpey Lectures on "An experimental study of certain visceral sensations" on May 1st and 3rd; and the Croonian Lectures on "The interpretation of gastric symptoms" will be given by Dr. Charles Bolton on June 5th, 7th, and 12th. All lectures begin at 5 p.m. Members of the medical profession will be admitted on presentation of card.

#### MEMORIAL TO SIR FREDERICK MOTT.

WE are glad to learn that the council of the Royal Medical-Psychological Association has decided to commemorate the life work of the late Sir Frederick Mott by publishing a memorial book, and for this purpose has appointed a committee consisting of Drs. C. Hubert Bond, F. L. Golla, Douglas McRae, Thomas Beaton, and J. R. Lord, the last-named acting as honorary secretary. Promises of scientific articles have been received from the leading exponents of psychiatry throughout the world; many of these papers will embody original work, and will be important contributions to neurology, psychiatry, and sociology. A fund has been opened to defray the cost of publication, and the committee appeals for donations, which should be sent to the treasurer, Dr. James Chambers, The Priory, Roehampton, S.W.15. In the course of our obituary notice on June 19th, 1926, we indicated the international influence of Mott's work and his great personal popularity. This memorial volume, prepared in his honour, will register steady progress in the branch of medicine which he did so much to advance, and a world-wide response to the appeal may be confidently expected.

## Hunter Bicentenary Celebrations.

### THE HOMES OF THE HUNTERS.

VICARY LECTURE BY DR. GEORGE C. PEACHEY.

At the Royal College of Surgeons of England on February 16th the Thomas Vicary Lecture was delivered by Dr. GEORGE C. PEACHEY, who took for his subject "The homes of the Hunters," and illustrated it by many topographical pictures and portraits.

Dr. Peachey said that he proposed to follow the footsteps of William and John Hunter in the London of the eighteenth century—the London of Hogarth and Gay, Fielding and Smollett, Johnson and Goldsmith. But the scene opened at Long Calderwood in Lanarkshire (Fig. 1), where John Hunter was born in 1728, the tenth child of his parents. Many of the children had died, probably all from tuberculosis, and only four came into the story—James, William, Dorothea (mother of Matthew Baillie), and John. It was William who bore the burden and heat of the day; he was the architect of his brothers' success and that of his nephew Matthew, and in our admiration for the genius of John it was only right that William should receive his meed of honour. James studied law, William was designed for the ministry, but abandoned the Church for medicine and practised surgery at Hamilton. In 1740 he made his way to London, finding lodging under William Smellie's roof in Pall Mall. He was fortunate in his teacher, for Smellie was described by Dr. Herbert Spencer as the greatest of British obstetricians. The instruction which Hunter received during those ten months with Smellie laid the foundation of his subsequent success, and even the uncouth manners of his teacher were useful in suggesting to him the value of a more courtly bearing, which subsequently procured for him his appointment to Queen Charlotte. He next became anatomical assistant to James Douglas, and tutor to Douglas's son. From Douglas he learned his love of books, acquired his zeal for anatomy, and was inspired to choose obstetrics as a means of future livelihood. Under Douglas's roof in Red Lion Square he lost no opportunity of acquiring knowledge. In 1741 he entered St. George's Hospital as a surgical pupil. In that year he lost his father, and not long afterwards his brother James, who had forsaken the law and had joined William in London, returned to Scotland to die. William succeeded on his elder brother's death to a small estate, but his mother, his two sisters, and his brother John were entirely dependent on this man of eight-and-twenty.

#### William Hunter a Pioneer in Antiseptic Midwifery.

In 1746 William Hunter announced his first course of lectures on anatomy at the Little Piazza, Covent Garden. John Hunter, tired of an idle country life, and hearing much of William's success, became his assistant, doubtless making his home with his brother during the next twelve

months at Mrs. Douglas's house in Hatton Garden. During this period John was initiated into the art of dissecting. In the summer he went to Chelsea Hospital to learn surgery at the feet of Cheselden, and later was surgical pupil at St. Bartholomew's. Soon afterwards William was elected to the staff of the Hospital for Lying-in Women, Brownlow Street, Holborn. From his subsequent movements it appeared to the lecturer that William Hunter had grasped the important principle that for the safety of the women he attended his practice should not

be conducted from premises which served at the same time for dissecting; therefore he took a large house in the Great Piazza, Covent Garden, which henceforth became the residence of himself, his brother John, and their pupils. At the same time he retained the apartments in the Little Piazza for anatomical purposes. This was almost a hundred years before Semmelweis was led to attribute puerperal fever to the carriage of sepsis from the attendant to the patient.

#### John Hunter's Early Career in London.

John Hunter evidently made up his mind at this time to follow surgery as his profession. In 1754 he entered as surgical pupil at St. George's, and in 1756 for a second course. At St. George's there were no restrictions; the appointments were open, subject to votes and influence alone. Whatever the evils of the system—and they were many—without it surgery would not have had its John Hunter. In 1756 he was appointed resident house-physician at St. George's, a stepping stone to the staff, but he retained the office only for five months, being anxious to return to the dissecting room and complete his researches. In the same year William Hunter removed to Jermyn Street, and the house in the Great Piazza served as the residence of John and the pupils and as the school of anatomy. An attack of pneumonia brought to an end John's labours in the dissecting room, and his dolorous family history pointed the need for prolonged change of occupation. In 1761, having obtained a commission as army surgeon, he sailed on foreign service. Before leaving England he had become a subscriber to St. George's, and it was at a board meeting there that he appeared again in history on his return from abroad after two years' absence. He was then, in all probability, living in lodgings in Russell Street, Covent Garden. Two years after his return he purchased the lease of ground at Earl's Court, on which he proceeded to build a residence (Fig. 2), and shortly afterwards he also became the occupier of a house in Golden Square.

#### William Hunter's Theatre.

Meanwhile William Hunter, having acquired competency for himself, and finding that his work continued to accumulate, resolved to give up teaching anatomy and to vacate the Covent Garden premises. He applied for a grant of

FIG. 1.—Long Calderwood, the birthplace of William and John Hunter.

FIG. 2.—John Hunter's home at Earl's Court, Kensington, 1764-1793.

land from the Crown for the building of a museum of anatomy, but his offer in that connexion failed of acceptance. Had it materialized the name of Scotland Yard, the chosen site, would have been associated in the public mind with the investigation of disease instead of crime. He had taken temporary premises in Litchfield Street, until, foiled in his design, he purchased a house in Great Windmill Street (Fig. 3), and began to build a theatre for himself. From 1763 until his death in 1783 William Hunter, with a succession of distinguished assistants, continued there his courses of anatomy. After his death the property passed to Matthew Baillie until, in 1831, its doors were finally closed. Of all the homes of William Hunter in London this alone, in part, remained. The wall in Great Windmill Street, now the back of the Lyric Theatre, was the actual frontage of the old house. The front portico had gone, the area remained, and behind the railings might be seen the basement windows. Through a side entrance to the north the actors and actresses now passed to their dressing rooms above, and a flight of steps was to be seen down which many a "resurrectionist" must have staggered under his ghastly burden. The stage of the theatre, which was sunk below the level of the street, formed the actual floor of William Hunter's dissecting room.

#### *The Estrangement of the Brothers.*

When William Hunter vacated Jernyn Street in 1768 he handed over the remainder of the lease to his brother, who, with his support, was elected surgeon to St. George's Hospital. This appointment enabled John to take pupils, one of the earliest and certainly the greatest of whom was Edward Jenner. The exact date of the termination of Jenner's residence in Jernyn Street was conjectural. He might or might not have been there in July, 1771, when, one Saturday evening, John wrote a letter to William telling him that he was to be married at eight the following morning at St. James's, Piccadilly. From his marriage onward John Hunter made good use of the house at Earl's Court. About that house, which was demolished in 1886, there lingered the romance of John Hunter's otherwise turbulent life. The estrangement between the brothers began about 1778, when, owing to some disagreement, John's lectures on the principles and practice of surgery, which had previously been delivered at his brother's anatomical theatre in Great Windmill Street, were given at No. 28 in the Haymarket. William Hunter, who had done so much for his brothers, and had secured for John

the opportunity of developing his talents, was no easy master. The opposition to his claims of discovery had perhaps embittered him. In 1778, for some reason, their ways parted, and the estrangement lasted to the end. John was not mentioned in William's will.

#### *Triumph and Tragedy.*

The museum, which was the darling object of John Hunter's life, requiring better accommodation, he decided to purchase the lease of a house in Leicester Square and the premises behind it. On the ground between the two he built a lecture theatre and a conversing room, and above them a museum and gallery. It was said that he spent £6,000 on the lease and the building. This house was his family residence. He had by this time been appointed surgeon extraordinary to the King. Honours were showered upon him, and the death of Percival Pott left him without rival in his profession. But two troubles assailed him, one an alarming malady whose recurring attacks made him in constant fear of death, and the other his financial responsibilities. For although he had earned as much as £5,000 a year he had saved nothing, and his family was unprovided for. Everything above his establishment expenses, the purchase of the Earl's Court freehold, and the lease in Leicester Square was swallowed up by his museum. These circumstances made him irritable and impatient of opposition, and

FIG. 3.—William Hunter's residence and School of Anatomy, Great Windmill Street, London.

worsened the relations, which were never good, between himself and his colleagues at St. George's.

The lecturer recited the melancholy history of that quarrel, which was terminated by Hunter's tragically sudden death, or perhaps not even terminated then, for at the meeting of the board following the tragedy no vote of condolence was passed, no official expression of sorrow was forthcoming. John Hunter's personal property was dispersed, the Earl's Court house was sold, and after debts had been paid only a balance of £1,500 remained. In 1799 the Hunter collections were purchased for £15,000 for the use of the public, and were entrusted to the keeping of the College of Surgeons, being moved in 1806 from Castle Street to Lincoln's Inn Fields.

"In the brilliant sunshine of modern surgical progress," added Dr. Peachey, "begun by Simpson with the introduction of chloroform anaesthesia and culminating in the magnificent triumph of Lister, our eyes are apt to be blinded to the debt we owe to the perseverance and the genius of John Hunter. 'Si monumentum requiris, circumspice.'"

### ROYAL COLLEGE OF SURGEONS.

#### HUNTERIAN FESTIVAL DINNER.

THE delivery of the Hunterian Oration by Sir Holburt Waring on February 14th was followed in the evening by a festival banquet given by the President and Council at the Royal College of Surgeons. The guests, representative of all branches of public life, were received by the President, Sir Berkeley Moynihan, and the Vice-Presidents, Sir Cuthbert Wallace and Mr. F. J. Steward.

After the loyal toasts had been honoured, and the "Memory of John Hunter" had been toasted in silence, the PRESIDENT, in a most felicitous speech, proposed the health of the many distinguished guests assembled that night to do honour to the College and its greatest son. He sketched in imagination the banquet that might have been given by that corporation and the great figures of the time who might have been entertained within its walls 200 years ago if they had known then that the child born

that day was destined to refound surgery on the basis of science. The claim, Sir Berkeley Moynihan said, might almost be made that science was substantially the only thing that had advanced in the last two centuries. In painting and sculpture, in architecture and literature, tastes and interests had changed, but when they regarded the work of those who lived centuries ago they must remain in a position of profound and reverent admiration.

THE EARL OF BIRKENHEAD, Secretary of State for India, responding to the toast, said that he was glad to meet so large a company of eminent surgeons on their own ground, although any layman must do so with mixed feelings. He had a great admiration for the surgical profession, without wishing to push the acquaintance too close in any individual case. Taking as his text the claim that the illustrious John Hunter was the first to introduce scientific surgery to the world, and a recent statement by their President that the highest point of technical achievement in surgery had perhaps now been reached, he indulged in a little irony,

at the expense of his hosts and their predecessors. He hoped that the surgeons of to-day were at least as right as those who went before them in the view they took of the perfection and the great resources of their art. His definition of surgery as "destructive medicine" was well received by the physicians present. Lord Birkenhead, in short, proved himself an adept in the branch of manipulative surgery that has been described as leg-pulling, and he ended, as was fitting, with an apology for the seriousness of his remarks on a festive occasion. The DEAN OF ST. PAUL's, in a short speech, expressed gratitude for the skill and generosity of surgeons at anxious moments in his life. It was noted that Dean Inge, when he made passing allusion to vitamins, adopted a pronunciation of that much-used word which was new to many of his audience.

In proposing the health of the Hunterian Orator, Sir GEORGE NEWMAN paid warm tribute to Sir Holburt Waring, describing him as a physiological surgeon and a successor in the great line of John Hunter, "the real father of preventive medicine." In his acknowledgement Sir HOLBURT WARING said that in his surgical work and study it had been his aim to follow in the footsteps of Hunter.

The company at dinner included, besides those named above, Lord Dawson of Penn, Lord Stanmore, Treasurer of St. Bartholomew's Hospital, and Lord Riddell, President of the Royal Free Hospital; Lord Justice Atkin and Mr. Justice Rowlatt; Sir George Makins, Sir Anthony Bowlby, and Sir John Bland-Sutton, past-Presidents of the College; Sir John Rose Bradford, President of the Royal College of Physicians; the Regius Professors at the two ancient universities, Sir Humphry Rolleston and Sir Farquhar Buzzard; the Treasurers of Lincoln's Inn and Gray's Inn; the Master of the Society of Apothecaries, Dr. R. Whiteside Statham, and the Masters of other City Companies, including the Barbers, who for centuries were united with the Surgeons; the Presidents of the Royal Academy of Arts and the Royal Institute of Painters in Water Colours, the Royal Society of Medicine, the Royal Institute of British Architects, and the Institution of Civil Engineers; the Directors-General of the Royal Naval Medical Service and the Army Medical Service; Sir D'Arcy Power, Sir Charters Symonds, Sir Dawson Williams, Sir Frederic Hallett, and Mr. H. de Vere Stacpoole; Sir Arthur Keith, Conservator of the Museum, Mr. Forrest Cowell, Secretary, and Mr. Victor Plarr, Librarian of the College; and the Editors of the *Lancet* and the *British Medical Journal*.

## HUNTERIAN SOCIETY.

### FESTIVAL DINNER.

THE annual dinner of the Hunterian Society was made an event of special importance this year, held as it was within five days of the bicentenary of John Hunter's birth. A very large company gathered at the Hotel Victoria on February 8th under the chairmanship of the society's president, Mr. MORTIMER WOOLF.

The principal guests were: Sir Douglas Hogg, K.C. (Attorney-General), the Lord Mayor and Lady Mayoress, the Recorder of London, the High Commissioner for India, Sir John Rose Bradford, P.R.C.P., the Presidents of the Royal Society of Medicine and the other metropolitan medical societies, Sir Arthur Keith, and Sir Dawson Williams.

The menu card was a striking production, the work of Mr. W. Thornton Shiells, with the Reynolds portrait of John Hunter in the centre, surrounded by sketches of his birth-place at Long Calderwood and of his week-end "cottage" at Earl's Court, as well as emblems of surgery and comparative anatomy. Sir ARTHUR KEITH, after explaining some of the devices for the benefit of the uninitiated, mentioned that there was present that evening one living link with Hunter in the person of Miss Hunter Baillie, who, despite her ninety years, had come to London to attend the celebrations, and who inherited her great-grand-uncle's outlook on life and something of his physical features.

The toast "In memory of John Hunter" was pledged in silence.

Sir DOUGLAS HOGG, in proposing the health of the Hunterian Society, said that he had always regarded the Church, medicine, and law as the three great healing professions. There was some

laughter at this, whereupon Sir Douglas added: "Well, I suppose it is true that you do not always heal your patients, but at any rate you try to follow our example!" As they had this object in common it was not unnatural that they should have something of the same experiences. Doctors and lawyers alike suffered from the fact that patients did not come to them until too late. Both depended for their success on the entire confidence of their patients. Law and medicine, again, were progressive professions. Every practitioner learnt something from every case he handled, although he was supposed to know all about the case before he began to handle it, and when he had once passed his examinations and been admitted to practice he was supposed to be capable of advising on the most abstruse problems of the science he had set out to learn. Law and medicine had this further in common—that they both demanded an unremitting industry. These professions were jealous mistresses, and brooked no rivals. There were, of course, differences between the two. It seldom or never happened that the doctor had to define legal problems, but it constantly happened that the lawyer had to define medical ailments. Perhaps that was the reason why doctors had so much less respect for the law than lawyers had for medicine. Both professions had their own standards of ethics, applied by their own chosen chiefs and recognized by a lay public who, however, did not always understand or appreciate them. There was formerly another link of resemblance, in that both doctors and lawyers wrote their prescriptions in a language which no one else could understand, but the lawyers gave up the use of Norman French 250 years ago, and he hoped that in another 250 years the doctors would be writing their prescriptions in intelligible English. But the great distinction of these two professions was the fact that with each the object and inspiration was the attainment of truth. It was a medical man who said that there were many more mistakes made by not looking than by not knowing, and it was a lawyer who said, "Be sure of your facts before you come to your theories." With both professions the ascertainment of truth was the first essential of successful practice. The members of both regarded their profession as imposing on them a responsibility to the public rather than as furnishing them with a means of livelihood. The generosity of the medical profession was well known to the world. Lawyers, though they lagged behind medical men in this respect, nevertheless did in the aggregate a great deal to assure for the poor of this country that expert help which they could not otherwise afford. Just as there were hospitals for bodily healing in every centre of population, so Sir Douglas Hogg desired to see a day when there would be "legal hospitals"—centres to which poor people could go for the advice they needed. In conclusion, he referred to the fact that he represented in Parliament the greatest medical constituency in the United Kingdom (Marylebone).

Mr. MORTIMER WOOLF responded in a pleasant speech in which he recited the achievements of the society in recent years, mentioning especially its long association with the City of London, and the fact that its monthly meetings, always held in the old City, sometimes at the Mansion House or in the hall of a City company, had an average attendance of one hundred. The traditional association of the Hunterian Society with the City of London was also emphasized by Mr. W. E. TANNER in proposing the health of the Lord Mayor and Corporation. The LORD MAYOR, in responding, assured the members that during his temporary residence at the Mansion House it would be more than an ordinary pleasure to welcome the society there.

Dr. W. LANGDON BROWN, in proposing "The Guests," said that although it was the common idea that they would all be forgotten in a hundred years' time, yet, as the present spate of centenaries proved, the passage of a century often added to a man's reputation. The toast had three respondents, the first being EARL RUSSELL, who, as a constitutional Labour peer, deplored the "revolutionary" character of recent legislation. Sir ERNEST WILD compared the achievements of John Hunter in medicine with those of John Howard in penology, the aim in medicine being the extinction of barbarism. Finally, Sir JOHN ROSE BRADFORD drew another parallel between John Hunter and William Harvey, describing Hunter's intellect as perhaps rather of the reservoir and Harvey's of the spring type; yet he acknowledged that Hunter, notwithstanding his great eminence in the accumulation of facts, resembled Harvey in possessing also a striking originality and fertility of idea.

## VOLUNTARY HOSPITALS AND PUBLIC AUTHORITIES.

### CONFERENCE IN LONDON.

A SPECIAL meeting was held, under the auspices of the Charity Organization Society, at Denison House, Victoria, on February 13th to discuss the question of the voluntary hospitals and the public authorities. Lord Dawson of PENN presided, and the large attendance included many persons well known in connexion with hospital and public health administration in London.

Lord Dawson said that the purpose of the meeting was to discuss how best to direct and co-ordinate London hospital accommodation. The first fact which had to be faced was that increased hospital accommodation was called for by the progress of medical treatment of disease, and by domestic circumstances and social needs. The demand had been met to a large extent by voluntary effort, recently reinforced by the utilization of some Poor Law hospitals. The work of these Poor Law—or better called municipal—hospitals was likely to grow in importance and magnitude. When the Poor Law Reform Bill became law the public authority in London would be responsible for over 100,000 beds. The question was whether two parallel and competing systems of hospitals in London were to be maintained or whether co-operation was possible. The big teaching hospitals of London were part and parcel of the national life. On them very largely the nation depended for its future supply of doctors; in them to a great extent new knowledge was "tried out" and made generally available. A wise statesman, so far from undermining them, would try to adapt them as leading and guiding elements in a large scheme. It was important to conserve their characteristics of initiative and freedom from that cramping routine which seemed to be inseparable from State-aided institutions. They were the embodiment of the voluntary spirit. Voluntarism in hospitals he would describe as management by bodies which did not owe their origin to State or municipal government. In London these hospitals were gathered under the aegis of the King Edward Hospital Fund, itself a magnificent example of voluntary effort, which aimed at influence rather than interference, and sought to co-ordinate the several institutions while keeping alive in each of them a certain independence of spirit. What was to be desired in the public interest? Should the public authority have under its control 100,000 beds and utilize the great experience of existing voluntary hospitals in building up a complete hospital system, or was it necessary to contemplate the prospect of all hospitals falling under bureaucratic control, with its inevitably rigid formulas and restraints? In passing, he affirmed that if the teaching hospitals of London were municipally administered so that all voluntary work in them was ended it would mean an addition of 8d. in the £ on the rates. The time had come for a fearless survey of the whole position.

Sir WILLIAM HAXER gave a brief historical survey of the gradual replacement of haphazard efforts by an organized system in dealing with the health of the community. The National Health Insurance Act had made it clear that the line of demarcation between State medicine and domiciliary medicine was no longer the same as that between preventive and curative medicine. To take one relatively small result, the notable decline in mortality from measles among children was clearly to be ascribed to co-operation between the Ministry, the Metropolitan Asylums Board, the county and borough councils, and the private practitioners in co-operation. The time had now come to make further advances for persons of all ages, and on both preventive and curative lines, there was work enough for all agencies which could be brought into the field. Competition between voluntary and official institutions could and should be avoided. Each voluntary hospital in London should form a nucleus functioning in close co-operation with associated health agencies, and in the living organism formed by the aggregation of such agencies there must be no schism. Such an organization would speedily bring about a fall in death and sickness rates and a rise in efficiency and working capacity which would open the eyes of the statisticians.

### The Case for the Voluntary System.

Dr. E. GRAHAM LITTLE, M.P., pleaded for the maintenance of the voluntary system unimpaired. The voluntary hospital was one supported mainly by voluntary subscriptions, gifts, or endowments; its permanent staff consisted of honorary physicians and surgeons; patients were freely admitted, any contributions they made being voluntary contributions, and the hospital was managed by an unpaid board elected by the subscribers. The note of the voluntary hospital was independence and clarity, and these qualities had attracted to its service the best men, lay and medical, for generations. Side by side with the voluntary hospitals another class of institution had long existed—the Poor Law infirmary controlled by boards of guardians. These institutions were still hedged about with restrictions, the legacy of their origin as part of the system of poor relief. Compared with the voluntary hospitals they lacked individuality, and their organization tended to be stereotyped, inelastic, and departmental. But as they were supported by the public purse they tended to become more and more competitors with the voluntary hospitals in equipment, though not in personnel, for in this latter respect they were less adequately supplied, on both the medical and the nursing sides, than was the case with the voluntary hospitals. ("No.") In London there were thirty of these institutions, with 19,000 beds, as against 130 voluntary hospitals with not quite 14,000 beds; but whereas, owing to their popularity, voluntary hospitals had waiting lists, and in fact could not deal with more than 70 per cent. of the demand upon them, the Poor Law hospitals had very large numbers of permanently empty beds—"No"—a proportion variously estimated, according to the district and the season, as from one-sixth to one-fourth of the total accommodation. The impoverished condition of the national finances made imperative the most economical use of the available resources. It had been estimated by expert local committees outside London, and by the King Edward Hospital Fund in London, that for voluntary hospitals in England and Wales to overtake the demand upon them 11,000 extra beds (3,000 of them in London) would be required, but there were from 20,000 to 30,000 beds empty at Poor Law institutions. This reserve of beds would enable the voluntary hospitals to deal with the calls now made upon them. It seemed obvious that the need of the moment was redistribution, both of functions and accommodation. There were several factors which explained why the voluntary hospitals had long waiting lists and the Poor Law hospitals thousands of empty beds. In the former institutions there was the atmosphere of personal service, given, not for money, but for love, a sense of individuality, and the ancient traditions. The Poor Law hospital, immeasurably improved as it had been during the last twenty years, suffered from two handicaps easily removable—the legal disqualification of pauperism which attached to patients—(A voice: "That has been removed since 1918")—and the rule that only patients from the district should be admitted. But the hospital had an inherent defect more difficult to change. The provision of out-patient and special departments, with the necessary medical and surgical personnel, would be immensely costly, and it was not likely in any case that the same quality of personnel would be secured by payment as was now forthcoming at the voluntary institutions.

Dr. Graham Little, in conclusion, referred to a method of co-ordination of medical services which Mr. Walter Spencer and he had proposed. The idea was to establish an advisory council to deal at first with the hospitals in the metropolitan area. It would be nominated on the one side by the King Edward Hospital Fund Council; and on the other by the Ministry of Health and the London County Council, always provided that the preponderant influence on the council should be essentially voluntary. The voluntary hospital in each area should become a nucleus of medical services for that area. Tentative efforts at co-ordination had already been carried out with encouraging success, but they had been somewhat haphazard. The precedent of some modern universities, where advisory councils representative of all interests concerned had been set up, might also be cited.

*The Case for a Municipal Service.*

Dr. HUMPHRY NOCKOLDS said that there were four main causes of the present position: the difficulties of the voluntary hospitals in finding money; the increasing population, more especially in the areas covered by large housing schemes; the progress of medicine and surgery, which required more expensive equipment; and the increasing desire of the general public for satisfactory accommodation and treatment. The first of these was a very serious difficulty. Resort had to be made to such expedients as "golden ballots," and yet, in spite of intensive efforts to obtain money, the dread spectre of the State drew near. Already the voluntary hospitals maintained certain services only by State subsidies. It was admitted that the voluntary hospitals in the London area were unable to cope with the number of patients requiring hospital treatment. The possible solutions were: (1) for the State to take over all hospitals, which would mean the destruction of the voluntary system, and would be the worst possible course to take; (2) for the local authorities to make grants to the voluntary hospitals, but these grants would have to be so large that no Government would ever sanction them without requiring popular representation, and, further, the voluntary subscribers would quickly disappear; (3) for the voluntary hospitals to be linked up with and to control the Poor Law hospitals, the local authorities finding the money (but as the voluntary hospitals had practically no co-operation among themselves, even after hundreds of years, they appeared to have no claim whatever to become the organizing authority for a unified hospital service); (4) for the local authorities to make a new departure and institute municipal general and special services, the Poor Law hospitals being the basis of the scheme. This last was, he believed, a really practical suggestion, and should, with the definite retention of the voluntary hospitals, form the basis of all reform. The unit must be large—for example, the county area. A strong medical representation, the obvious nucleus of which would be from the staffs of the voluntary hospitals and from the direct medical control of the municipal hospitals, would prevent "the creeping ulcer of bureaucracy." But the representation must be of really active working medical men. He thought the Poor Law hospitals not unworthy to come into such an organization. They had already taken over a part of the burden of the voluntary hospitals, and although they suffered under manifest disadvantages in their origin and management, the latter being rather too near the "vote," and in lack of directivity in medical matters from the Poor Law section of the Ministry of Health, they had nevertheless shown a great faculty of adaptation.

Dr. F. N. KAY MENZIES, who said that he was not present as medical officer of the London County Council, gave some figures to show that financially the position of the voluntary hospitals had improved greatly since 1920. In 1920 the ordinary expenditure of the hospitals of England and Wales exceeded ordinary income by £500,000, and in 1926 ordinary income exceeded ordinary expenditure by £250,000. But it was of no use shutting one's eyes to the shortage of accommodation, intensified in many areas by the housing shortage, and everywhere by the growth of the "hospital habit." The public authorities were concerned now much more than formerly with the treatment of the individual. The Poor Law authorities in London, including the Metropolitan Asylums Board, had actually got between 70,000 and 80,000 beds for the treatment of the sick. He begged that these interested would get it out of their minds that the taking over of a complete municipal hospital service was too big a job for the London County Council; it was already doing bigger jobs in other departments, such as education and housing. Not only could it bring such a service under a single control, but it could do it extraordinarily well. But if the voluntary hospitals refused to co-operate in such a service it would mean in time their extinction. In London there had been for many years complete and harmonious co-operation between the London County Council and the voluntary hospitals, towards the work of which the council paid about £150,000 a year without asking for any voice in the appointment of the medical staff. He was unable to understand why there

should be any difficulty in adapting the facilities provided by voluntary hospitals and public authorities to the needs of the community.

*The Poor Law Hospitals Defended.*

Miss FULFORD (chairman of the Fulham Guardians) declared that in the Poor Law hospital with which she had had to do there had been for the last five years an entire absence of empty beds. It had been said that the atmosphere in Poor Law hospitals was different, but she felt that all who had had experience of them must know what magnificent services were rendered both by doctors and nurses to the chronic and helpless cases with which they were mostly full. She denied that the guardians were swayed by the vote, and entirely repudiated the statement that they did not receive encouragement from the Ministry of Health.

Mr. MONTVIER (Edmonton Guardians) asked Dr. Graham Little what was the difference between a "Poor Law appendix" and a voluntary hospital appendix. The Poor Law vacant beds existed only in the fever hospitals of the Metropolitan Asylums Board. Dr. Graham Little had said that "of course" in any unified system such as he had outlined the voluntary hospital element must be predominant. The speaker would really like to send to medical spokesmen Thackeray's *Book of Snobs*. If he went into any co-operative movement it must be really co-operative—not the sort of co-operation of the lady who went for a ride on a tiger. He wanted to know whether medical officers changed their skins when they went into a Poor Law hospital. One of the officers at Edmonton was also at St. Bartholomew's; was he animated by a different spirit in each of the two places? He thought the war ought to have knocked any such nonsense out of their heads.

*The Position of the Hospital Subscriber.*

Lord RIDDELL said that it was evident a new situation faced the hospital world. He had been recently to Edmonton, from which the last speaker came, and he had never in his life seen a better hospital, or one better equipped or showing a better spirit. But if the Royal Free Hospital, with which he was identified, were linked up with Edmonton he wondered whether he would still be prepared to put his hand in his pocket for the benefit of the Royal Free when at Edmonton he saw just as good work being done with a State or municipal subsidy. Although he was a great admirer of rate-supported hospitals, it seemed to him that institutions run by public bodies usually lacked the spirit of research, diversity, and competition. But he hoped that this great hospital problem would be solved without acrimony, and he thought it unfortunate that medical men in voluntary hospitals rather looked down upon other institutions.

Mr. JAY (propaganda secretary of the King Edward Hospital Fund) said that the task ahead was to convince the public that the voluntary hospitals still fulfilled a function different from others. He suggested a differentiation whereby the voluntary hospitals with their special equipment would be used mainly for specialist treatment, acute cases, and surgery, while the Poor Law hospitals would deal with chronic cases and cases which, for other reasons than that special treatment was necessary, could not suitably be treated at home.

Lord DAWSON, in closing the discussion, said the point had emerged that both classes of institutions were necessary in their respective spheres. But the voluntary hospitals were no longer able to cope with their problem. Those hospitals could do a work not open to others, simply owing to the fact that they had gained a certain prestige and had attracted around themselves the *élite* of talent in the medical world. It was the highest ambition of men of ability to get on their staffs. But the danger of ancient institutions was that they failed to realize fresh needs. The municipal hospitals were also doing good work. What was needed was a friendly conclave to review the position and endeavour to bring about some reassignment of duties. He was confident that the teaching hospitals would rise to the occasion. Their position would be important, more important than ever, but there need be no question of

dominance. Almost everything in this country came about by mutual agreement. He referred to the report of the Consultative Council in which he had a hand, and declared that it still held the field; if there had been a proper classification of hospitals according to that report there would by now have been much better co-ordination among the new communities. He believed that popularly elected bodies would increasingly have to nominate, or consent to the nomination of, bodies of experts detached from themselves on whom the immediate responsibility of management would rest. Incidentally this would furnish a reply for the elected person when assailed by his constituents; he would be able to say that, whatever he and his colleagues might feel, they must trust the appointed experts. Medicine, like other professions, was becoming more and more technical, and this fact, so far as hospital provision and management were concerned, would have its bearing on the shaping of government.

## Scotland.

### Relic of David Livingstone.

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow on February 6th, Mr. G. H. Edington, the president, in the chair, the surgical pocket-case used by David Livingstone during his daily work in Africa was presented to the Faculty by Dr. Freeland Fergus, on behalf of Mr. Hilliard, surgical instrument maker in Glasgow, to whom the relic belonged, but who was prevented by his state of health from attending the meeting. In the course of a letter from Mr. Hilliard it was recalled that Dr. Livingstone had been born at Blantyre, some seven or eight miles distant from the hall of the Faculty, and had obtained his licence to practise from the Faculty of Physicians and Surgeons at Glasgow. Through Mr. Hilliard's influence the instrument case which belonged to Dr. Beatty, R.N., the surgeon on board the *Victory* at the battle of Trafalgar, had been, some years ago, presented to the Royal Faculty of Physicians and Surgeons. Dr. Fergus mentioned that Mr. Hilliard had been the close friend of Dr. Livingstone's son, Mr. W. Oswald Livingstone, from the old High Street College days. This intimate connexion brought him into contact with Livingstone's supporters and patrons, including James Young and Sons, Gordon Bennett of the *New York Herald*, and Henry M. Stanley. In 1899 Mr. Hilliard had followed the steps of the explorer in many districts, including the flourishing town of Livingstone and other places bordering on the Zambesi. Many offers had been received for the relic from wealthy collectors in America, London, and Scotland. Dr. Fergus added that although Mr. Hilliard was not a member of the medical profession, he had been connected with it all his life, being born in the Royal Infirmary, where his father, as cutter and instrument maker, had at that time an official residence. Dr. Fergus spoke of Dr. Livingstone's perseverance and self-denial in surmounting difficulties.

### Aberdeen Royal Mental Hospital.

The 127th annual report of the Aberdeen Royal Mental Hospital has just been issued. The physician superintendent, Dr. R. Dods Brown, states that on December 31st, 1927, there were 788 certified patients on the register; the number of admissions had been 161, of discharges 102, and of deaths 65. The daily average number of certified patients resident had been 792, and including the voluntary patients the daily average number had been 831. The total number of patients treated during the year had been 1,025, or 18 more than in the previous year. With regard to the types of insanity from which patients had been suffering, 56 of the admissions were due to manic-depressive insanity, and in 26 of these melancholia was present. Twenty-eight of the admissions had been cases of infection-exhaustion psychosis, and in many of these patients the physical health had been very unsatisfactory. Thirty-eight had been suffering from dementia praecox, and 23 from dementia due to senility or organic brain disease. Four had been cases of idiocy, 4 of epileptic insanity, 4 of general paralysis, and 3 of paranoia. One patient admitted

had been found to be not insane. Of the total admissions 122 had been sent in for the first time, while 28 had had one previous breakdown, and 11 had had more than one prior attack. Thirty-seven patients had been received on the voluntary system, constituting 35 per cent. of the private admissions. Of the total population in the asylum 44 were voluntary boarders, of whom only 1 was rate aided. Attention is again drawn to the desirability of voluntary admission at an early stage of the disease, when it is presumably in an unconfirmed and still curable state. With regard to causal conditions, it is pointed out that of the 161 admissions 51 of the patients were suffering from some bodily disease, such as disorder of the heart, kidneys, and lungs. Alcohol was assigned as the cause in 15 cases, venereal disease in 9, and epilepsy in 8, while in 14 cases mental anxiety and worry appeared to be the cause. Among the 102 discharges, 51 patients had recovered, this being 32 per cent. of the number admitted. The 65 deaths constituted 6.8 of the total number under treatment, and included 3 patients who were admitted to hospital in a dying condition. This number included 10 cases of disease of the nervous system (of which 6 were general paralysis), 19 disease of the circulatory system, 19 lung disease (including 12 from pulmonary tuberculosis), 8 disease of the abdominal organs, and 5 cases in which exhaustion occurred in the course of acute psychosis. Reference is made to the treatment of general paralysis by the artificial induction of tertian malaria, which was introduced in 1917. It is mentioned that the most which can be hoped for is that the disease will be arrested and a mental and physical improvement brought about. So far no patient in this institution could be considered as having improved sufficiently to permit of discharge, although the majority of those so treated had benefited both mentally and physically. Attention is also drawn to the satisfactory results which had been obtained from the "protein shock" treatment. Ninety-two patients had been put under ultra-violet ray treatment, and in cases which were anaemic, poorly nourished, and below normal weight, benefit had been obtained as regards gain in weight, increase of appetite, better sleep, and disappearance of anaemia. Mental improvement in melancholia had also been noticed from this form of treatment. Similar results had been obtained by natural sunlight therapy during the summer months.

### Paratyphoid Fever at Galashiels.

The outbreak of paratyphoid fever at Galashiels reported last week (p. 236) has attained more serious dimensions than seemed likely after the check which occurred at an early stage. Up to the end of last week the number of notified cases had been practically 100, of which 70 had been admitted to the Sanderson Hospital, where the maximum of accommodation had been obtained by the removal of other infectious disease to Hawick; the epidemic was generally mild, three by February 9th. The outbreak had become general over the town, and the persons affected were of all ages, from infants to persons over 70 years old. In only two instances, however, has more than one person been affected in a single household. The water supply of the town, which is of comparatively recent installation, has been found to be clear of bacteria of the paratyphoid group, and the original channel of infection has not yet been discovered. Cases have also been reported from the neighbouring counties of Peeblesshire and Roxburghshire.

### Public Health Regulations in Scotland.

The Scottish Board of Health has recently issued two leaflets dealing with the prevention of epidemic, endemic, or infectious disease. By one of these the regulations dealing with infective jaundice issued in 1927 are extended until December 31st, 1932. Under these regulations infective jaundice was made a notifiable disease. The second leaflet deals with malaria, dysentery, acute primary pneumonia, and acute influenza pneumonia. These disorders are made notifiable diseases from January 1st, 1928. Every medical practitioner becoming aware that a person upon whom he is in professional attendance is suffering from one of these disorders is obliged to transmit a notification thereof to the medical officer of health

of the district on the usual form, and is entitled to a fee of 2s. 6d. for each notification. On receipt of a notification the medical officer of health is to make such inquiries and take such steps as are necessary for investigating the source of infection and preventing its spread. In regard to preventing the spread of malaria, it is to be a duty incumbent on the medical officer of health to supply the patient with efficient mosquito netting, to ensure that he receives the necessary quinine treatment and proper advice as to the continuation of this, and also proper advice as to the precautions to be taken to prevent the spread of infection. It may be remarked that this notification applies also to malaria induced for therapeutic purposes, and in such cases the notification is to be made on a special form. Powers are also given by these regulations to medical officers of health in regard to disinfection of the occupants of houses or premises where typhus fever or relapsing fever has broken out, and also in regard to enteric fever and dysentery, empowering the medical officer of health to cause persons who are likely to carry infection with one of these diseases to discontinue any occupation connected with the preparation or handling of food or drink for human consumption, and to ensure that suitable measures in respect to cleansing, disinfection, etc., are carried out.

## Ireland.

### Belfast Board of Guardians and their Milk Supply.

THE following important and unusual recommendation, made by the Requisition and Purchasing Committee, was adopted at a meeting of the Belfast Board of Guardians:

The contractor must permit his cows to be examined monthly by the veterinary surgeon appointed by the guardians, and, failing disposal of any animals affected with tuberculosis, or in any other way in an unsatisfactory state of health, the guardians will cease to order any further quantities, and the contract will be determined. Conditions of conveying the milk must be such as to secure a clean, pure supply.

It was further recommended that the board's solicitor be instructed to amend accordingly the form of tender and bond, and that definite instructions be given to the officer appointed under such conditions, so that he might clearly understand the board's instructions.

### Medical Referees under the Insurance Act in Northern Ireland.

Resolutions were submitted by the Tyrone members at a meeting of the North of Ireland Branch of the British Medical Association, held in Belfast: (a) protesting against the appointment of local referees for reviewing the certificates of local certifying doctors, and against the scale of payment if the appointments are approved, and suggesting the appointment of another whole-time certifier, thus unifying the appointments in the North and South of Ireland; (b) protesting against the form of medical certificate required to be presented to the judge by a juror or witness at the time of civil or criminal trials, because the certificate required the name and particulars of the complaint from which the juror or witness might be suffering; and (c) urging consideration of the recommendations of the Poor Law Commission, and asking the Government to appoint a Minister of Health.

### Kildare Board of Health.

Dr. J. A. Harbinson, who has recently been appointed county medical officer of health for Kildare, in his report to the Health Board stated that he had visited several of the district medical officers of health with a view to familiarizing himself with the work carried out by them in their districts. He added that he had asked the secretary of the County Medical Committee to convene a meeting of the members so that he could discuss with them their duties under the Public Health Acts, and consider how they might co-operate in the establishment of an efficient public health service for county Kildare. Dr. Harbinson informed the Health Board that he was collecting figures with a view to putting into effective operation the medical inspection of school children, the Vaccination Acts, and the Midwives Act, 1918.

## England and Wales.

### Board of Control.

THE forthcoming retirement is announced of Sir Frederick Willis, K.B.E., chairman of the Board of Control. He succeeded Sir William Byrne in that office in 1921, and has been a member of the Civil Service for forty-two years. Members of the British Medical Association will recall that Sir Frederick Willis took a prominent part in the discussion by the Section of Mental Diseases at the Edinburgh Annual Meeting on the report of the Lunacy Commission. The retirement, at a critical time for lunacy administration, of a public servant of such ability and influence will be widely regretted by members of the medical profession. During his chairmanship of the Board Sir Frederick Willis has had to deal with many difficult and important problems affecting the mental health of the country and the liberty of the subject. He has done much for the welfare of the insane, both by his enthusiasm for progress and by the friendly relations he has maintained with medical superintendents of mental hospitals and with local authorities. He will be succeeded as a commissioner and chairman of the Board by Mr. L. G. Brock, C.B., who has been for some years past a principal assistant secretary of the Ministry of Health. Mr. Brock is a member of the Dental Board of the United Kingdom, and for two years was acting secretary of the National Health Insurance Commission before this was merged in the Ministry of Health.

### Cancer Research in Manchester.

In July, 1924, Dr. Veitch Clark, medical officer of health for the city of Manchester, established a provisional local cancer committee, which, after holding several meetings, was reconstituted in the following December as the Manchester Committee on Cancer, to include representatives of all organizations in the city concerned with this problem. The committee has now published a report of the three years of its work. In November, 1925, as the result of an appeal, over £12,000 was received, and a limited scheme of investigation was commenced in May, 1926, in close co-operation with the university. Special research has been undertaken by Dr. C. C. Twort and Dr. H. R. Ing to determine the etiology of mule-spinners' cancer, and grants are being made to Dr. K. V. Bailey, who is studying cancer of the cervix, and to Dr. J. B. Duguid for his work on the incidence of intrathoracic tumours in Manchester. Two special investigation officers, Dr. Gretta Wardle and Dr. J. Murray, were appointed to conduct a statistical research into the results of treatment of cancer of the breast, to bring about the establishment of a uniform system of record keeping of all local current cancer cases, and to collect histological specimens. They have been able to report that 80 per cent. of patients with cancer of the breast who are treated by modern surgical methods in the early stages survive for at least ten years, whereas without operation the average expectation of life does not exceed three and a half years from the onset of the disease. The committee arranged a post-graduate course of twelve lectures for medical practitioners on various aspects of the cancer problem during the winter 1926-27. It is announced that these lectures are to be published for propaganda purposes, together with a summary of what has been accomplished by the special investigation officers. In order to continue and extend the work it has now been decided to form a Lancashire, Cheshire, and North Wales Council of the British Empire Cancer Campaign, and to launch in March an appeal for funds over the area concerned on similar lines to that which has been so successful in Yorkshire.

### Central Midwives Board.

At the meeting of the Central Midwives Board for England and Wales, held on February 2nd, with Sir Francis Champneys, Bt., in the chair, a letter was read from the secretary of the Tynemouth Joint Hospital Board stating that a conference of representatives of various training schools affected by the Board's policy with regard

to lectures was being convened with a view to joint representation being made, as a result of which it was hoped that the policy of the Board might be modified, and asking that in the circumstances Dr. Williamson's approval as a lecturer at Tynemouth might be extended from March 31st next. The Board agreed to reply that if it could receive assurance that arrangements for convening the conference were actually in progress, and that an early presentation to the Board of the representations of the conference was likely, the Board was willing to extend the approval for a short period. The secretary reported that the Nursing Homes (Registration) Act, 1927, repeals that portion of the Midwives and Maternity Homes Act, 1926, which deals with the registration of maternity homes, and provides for registration and inspection of nursing homes generally (including maternity homes) by county councils (subject to certain powers of delegation) and county borough councils. Provision is made for delegation by county councils of any of their powers or duties in certain circumstances. It was resolved to inform the Minister of Health, the County Councils Association, and the county councils:

"That the Board is still of opinion that the supervision of maternity homes ought to be in the same hands as the supervision of midwives; that delegation of powers and duties relating thereto under the Act is undesirable, and ventures to express the hope that the Minister and the county councils will grant no delegation in respect of maternity homes, except in those cases in which delegation has already taken place under the Midwives Act, 1902."

## India.

### Medical Education in Bengal.

INTERESTING details about the progress of medical education in Bengal are contained in Lieut.-Colonel J. C. Holdich Leicester's report on the working of hospitals and dispensaries during the three years 1923, 1924, and 1925. The four Government medical schools of Bengal—namely, Campbell, Dacca, Ronaldshay, and Lytton—now accommodate 1,300 students, the last named having been formally opened in July, 1923. A scheme for the establishment of five new medical schools in other places is under consideration, and attempts are being made to enlarge the local hospitals so as to render them suitable for clinical teaching and bring them up to the necessary standard of efficiency. Scholarships tenable in medical schools have been made available for students of the depressed classes. Private generosity has played a conspicuous part in the establishment of medical schools, and a new one, named the "Calcutta Medical Institute," has been recognized provisionally for five years from 1925, by the Bengal Council of Medical Registration, as an institute qualified to prepare students for the State licentiate examinations. Six other medical schools have also been started by private enterprise, but so far none has matured sufficiently for recognition. The School of Tropical Medicine and Hygiene in Calcutta, in connexion with the Carmichael Hospital for Tropical Diseases, provides two six months' courses of instruction, of which one covers the work for the diploma issued by the Faculty of Tropical Medicine of Bengal, and the other gives instruction for the diploma in public health of the Calcutta University. The school has organized also a three months' course of instruction for the licence in tropical medicine and hygiene for Bengal. It is stated that the courses of instruction, both in tropical medicine and hygiene, have been recognized by the Conjoint Examining Board in England. The teaching and research work at the School of Tropical Medicine are controlled by the Government of Bengal, assisted by the Faculty of Tropical Medicine and the Surgeon-General. Generous donations towards the school and hospital are provided by the Indian tea, jute mills, and mining associations, and by private benefactors. The Indian Research Fund Association has endowed a number of special investigations of various

tropical diseases and their treatment, some grants for medical research being made by the Government of India. In 1923 the Government sanctioned the establishment of therapeutical and teaching departments for diseases of the ear, nose, and throat in the medical college and hospitals in Calcutta, and the payment of two independent medical practitioners as honorary physician and surgeon; two senior officers have also been appointed as physician and surgeon to the out-patient department. The establishment of a dental school in Calcutta is under consideration, and an extern maternity department has also been opened. During the three years there has been in Calcutta a net addition of eight medical institutions, raising the total number to thirty-two, of which nineteen have accommodation for in-patients in over 3,000 beds.

### Health Progress in Assam.

The general decline in the death rate in Assam continues, though there was a slight increase in 1926 owing to outbreaks of cholera. The deaths from kala-azar are steadily diminishing, although no additional organization of treatment and survey has been found necessary; it appears, therefore, that this disease is under control and that its further spread has been arrested. Treatment at the special dispensaries is growing in popularity, and the work of civil surgeons in infected districts in supervising the campaign of their subordinates against kala-azar is proving very effective. In areas where the disease is particularly prevalent special hospitals and additional dispensaries have been established, staffed by expert officers. Wherever the disease is suspected in other areas trained investigators proceed there immediately and provide treatment for any requiring it; the value of such systematic programmes has now become apparent. The cholera death rate has risen as the result of an epidemic which spread from one locality. Cholera inoculation was adopted as a preventive measure with excellent results, thus limiting the spread, despite the infection of the rivers. Anticholera inoculations are becoming increasingly popular in Assam, where very little vaccination was used, except in tea gardens, prior to 1924. There is, however, a regrettable shortage of fully trained workers for combating epidemics in Assam, where only three epidemic units at present exist. Major T. D. Murison, director of public health, in his annual report for 1926, expresses the hope that the public health department will soon be very considerably strengthened, in order that more effective resistance may be made to the spread of epidemics. Public health propaganda is active, and lectures and demonstrations are given on such prevalent diseases as malaria, kala-azar, cholera, and small-pox. Lantern slides have been found very effective; gramophone records are employed in Bengali and Assamese; numerous pamphlets and leaflets, containing simple illustrations, have been distributed to the public in general, as well as to the schools, and prizes are awarded to the children and the teachers as the result of examinations in public health. The local authorities are widely co-operating in this activity.

### Bombay Medical Council.

At the last meeting of the Bombay Medical Council an application was received from the Mysore University for recognition of its L.M.P. examination. The council declined the application on the ground that, in accordance with a communication by the Government of India, any institution not mentioned in the schedule of the Indian Medical Degrees Act which desired to have a diploma recognized, should become affiliated to one of the institutions so mentioned. This had not been effected in the case of the Mysore University, and the council did not consider, therefore, that it had power to accede to the request. It was decided that in the case of general practitioners the use of the words "physician and surgeon" after their names might be allowed, and that Rule 22 of the Code of Medical Ethics issued by the council should be amended accordingly. The council considered the case of one practitioner who was alleged to have been guilty of infamous conduct in a professional respect; judgement was postponed to the next session.

## Correspondence.

### THE ACUTE ABDOMEN.

SIR.—Mr. Flint's article on the acute abdomen in your issue of February 11th (p. 209) lays stress on many points of great importance. His main thesis—the need for early diagnosis and treatment—indicates the only line along which much progress is likely to be made until greater knowledge permits prevention of the underlying morbid conditions which give rise to these abdominal emergencies.

In these circumstances it is a pity that Mr. Flint should have lent his name to the use of the word "rigidity" in describing the condition of the abdominal wall in inflammatory diseases. How often has one known valuable time lost because—so one is told—there has been no "rigidity" present! Rigidity, of course, is not a sign of early abdominal inflammations at all, and indeed is rarely met with except in cases of perforation. What is found is a varying degree of muscular "resistance."

This protest, Sir, is no academic quibble. There are very many medical students who pass out into practice, year by year, without appreciating the value of this distinction and the importance of that degree of increased muscular resistance which is only to be detected by the trained and sensitive hand. It is the persistent use of the word "rigidity" by their teachers which is responsible for this state of affairs.

In a paper where there is so much that is helpful and suggestive it is perhaps ungracious to be so critical, but to one other point I must refer. Surely a tumour felt in the rectum should have no place among the early signs of intussusception. It is true that occasionally an intussusception does reach the rectum with astonishing rapidity, but in how many is this only a late and dangerous stage? It cannot be too strongly emphasized that in every suspicious case—that is, where blood and mucus without faeces are passed by a baby, with periodic attacks of screaming—the diagnosis of intussusception can be disregarded only after the gravest consideration. Even then it should not be rejected without an examination under an anaesthetic, which sometimes reveals a "tumour" high up under the liver.

I agree with Mr. Flint when he says that much of the responsibility rests upon the patient and his friends. Their attitude of necessity reacts upon the doctor, who dares not saddle himself with the reputation of always "flying to the knife." This will not be set right until it becomes the recognized practice to send to hospital "for observation" even those cases which merely suggest acute abdominal disease, if they do not clear up *within a few hours* with rest in bed in the Fowler position, starvation, heat to the abdomen, and an enema.—I am, etc.,

Liverpool, Feb. 13th.

JOHN T. MORRISON.

SIR,—To those who know what they are talking about Mr. Flint's paper on the acute abdomen (February 11th, p. 209) comes as a great disappointment. I see no hope of success in any publicity campaign if those directing it are still talking to their fellow practitioners in terms of faecal vomiting, absolute constipation, tympanites, and sausage-shaped swellings. The general practitioner who substitutes careful observation and high enema for immediate exploration in suspected cases of acute abdominal mischief is asleep. It is regrettable that so many practitioners think there can be no acute lesion in the absence of rigidity.

Many times I have removed a totally gangrenous appendix within five hours of the initial symptom, and have blessed the practitioner who sent in the case because "he didn't like the look of it." I have seen babies die of shock within a few hours of the onset of an intussusception; Richter's hernia is still met with, and a strangulated Meckel's diverticulum is no rarity. In view of these conditions, what substitute is there for immediate laparotomy in safe hands? Fancy teaching the value of high enemata in such cases! May the fates protect Mr. Flint should he develop an acute abdomen.

I teach my students that classical symptoms are a clear indication (in cases of intestinal obstruction) that the case has been neglected, and lay the utmost stress on a rising pulse rate as the surest indication of the necessity for exploration. All these cases should be sent early to hospital for observation by properly trained, competent, and, of course, paid resident surgeons. Here, as elsewhere, the voluntary system cracks—but that is another story.—I am, etc.,

Glasgow, Feb. 13th.

W. RANKIN.

### THE FUTURE OF OBSTETRICS.

SIR,—May I be allowed to make a few comments on the letter of Dr. A. Z. C. Cressy in your issue of December 10th, 1927 (p. 1117), which has just reached me. He is apparently unwilling to "look on and allow Nature to take its course," and claims that Nature does not often run a normal course in present circumstances. Perhaps poor Nature does not get the chance. He then proceeds to give a list of conditions and their appropriate treatment, postulating "strict asepsis as regards patient, doctor, nurse, and surroundings." Either he uses the words "strict asepsis" in an unusual sense, or he succeeds in achieving what I have never seen achieved.

It has been my privilege to take part in the instruction of students, male and female, graduate and undergraduate, drawn from about twenty different universities. I can categorically assert, in spite of university requirements and the requisite signatures, that a large number, probably the larger number, of medical students in the British Isles deliver not more than ten women before they become qualified. A large number of students spend only one month doing practical midwifery, while some "lucky" ones finish all their cases in one week. Not 5 per cent. of medical students apply forceps before they become qualified. The number of obstetric house appointments is small.

The first question that I want to ask is, where and how does the recently qualified practitioner obtain his experience, and at whose expense? The second question is, how can a busy practitioner, however skilled he may be and however much experience he may have had, possibly afford the time to conduct a case properly on conservative lines?

It has been conclusively proved at all the great maternity hospitals that the application of forceps, even when the head is on the perineum, definitely increases the risk of morbidity. Surely Dr. Cressy will not claim that the average practitioner is more successful at such an operation than the skilled assistants in maternity hospitals. Yet some practitioners apply the forceps in 60 per cent. of all their cases. Having been responsible for some thousands of cases of labour I can confidently assert that Nature *plus* an enema *plus* a catheter *plus* morphine and scopolamine or tincture of opium can deliver more than 95 per cent. of all pregnant women in Great Britain. Nature may require time and cause pain; but she will never be responsible for an annual bill of 3,000 maternal deaths and 50,000 (?) maternal invalids. Axis-traction forceps should seldom be required, as the head should almost invariably come to the outlet of the pelvis before the forceps are applied.

I think most people would agree that in the ideal State every woman should be attended in labour by a doctor who has had special training in midwifery and has learned to be conservative. As such conditions are not possible I am convinced that the average woman is better off if she is attended by a midwife, who will send for the doctor when necessary; she has patience, and has time to wait. We all long for an improvement in our maternity service. I am convinced that the main need is for large maternity hospitals serving different areas and staffed by whole-time physicians, and I am equally convinced that those hospitals will have to be built by the State.

May I, in conclusion, ask Dr. Cressy to read, or re-read, the following papers: (1) The report on maternal mortality, by Dame Janet Campbell. (2) The maternal mortality in the midwifery service of Queen Victoria's Jubilee Institute, by J. S. Fairbairn (BRITISH MEDICAL JOURNAL, January 8th, 1927). (3) A plea for drastic reforms in the teaching and practice of midwifery (*Lancet*, September 25th, 1926). (4) The report on maternal mortality in New

Zealand, drawn up for the Government by Dr. Henry Jellett.

As the solo person responsible for the training of medical students in midwifery in this country, I greatly deplore this and similar attempts to justify "meddlesome midwifery."—I am, etc.,

G. W. TITCOMB,  
Professor of Obstetrics and Gynaecology,  
Bangkok.

Bangkok, Siam, Jan. 10th.

#### TREATMENT OF ACUTE PNEUMONIA.

SIR,—I read Dr. Maidlow's letter (BRITISH MEDICAL JOURNAL, February 11th, p. 258) with very considerable relish. It seems just possible that a few communications of this type might succeed in arousing the profession from its lethargic self-complacency. At all events, he is entitled to our best thanks for his genial banter, as underlying it there are indisputable facts which do no great credit to anybody; and least of all, I think, to consulting physicians, who sometimes impede progress by mistaking their own impressions and ex-cathedra pronouncements for realities, just like ordinary general practitioners.

But "to err is human," and none of us is immune. Still, I feel able to enjoy Dr. Maidlow's little jokes with a comparatively clear conscience, as I have already offered the best solution I could to this very important problem. Dealing with one aspect of the problem—the specific treatment—I wrote as follows two years ago:

"Material for the final assessment of the value of specific treatment in early pneumonia can hardly be anticipated from the isolated efforts of individual private practitioners under present conditions. If pneumonia were dealt with on similar lines to diphtheria as regards diagnosis, specific treatment, and notification, the outlook would be more promising. In connexion with pneumonia, however, I suggest that it would be desirable not only to provide pathological facilities and vaccine or serum, but also some sort of clearing house, preferably as a department of the public health service, which would collate clinical records. This would eventually permit of a sufficiently wide scrutiny of results to settle the matter to the satisfaction of everyone, except perhaps the occasional crank who refuses to be influenced by evidence."

May I inquire what objections there are to an attempt at a solution of this aspect of the problem on these or similar lines? I suggest that the death rate and the present chaotic position in regard to treatment demand that "something should be done."—I am, etc.,

Manchester, Feb. 11th.

J. STAVELY DICK.

#### FATALITY RATES OF SMALL-POX.

SIR,—Dr. Percy Stocks, in his letter in your issue of February 4th (p. 197), makes a statement which embodies so profound a truth that I should like to be allowed to reiterate it. He says: "Epidemics come and go according to laws which we do not yet understand, and which involve many factors other than vaccination." When, however, he states, later on, that "the only conclusive proof of the efficacy of vaccination must consist in comparing the vaccinated with the unvaccinated at the same ages in the same town and during the same epidemic," I feel obliged to ask him just what he means by the expression "the efficacy of vaccination." It may mean two entirely different things—namely (1) efficacy to protect the individual, and (2) efficacy to protect the community. I quite agree that the comparison Dr. Stocks suggests does prove the efficacy of vaccination to protect the individual, but I submit, with all respect, that such a comparison does not prove the efficacy of vaccination to protect the community; and I suggest that, vaccination or no vaccination, epidemics will continue to come and go, as Dr. Stocks says, "according to laws which we do not yet understand, and which involve many factors other than vaccination."

It is just because there has been so much confusion of thought between the efficacy of vaccination to protect the individual and its efficacy to protect the community—so many people thinking that proof of the former implies proof of the latter, whereas in reality it does nothing of the kind—that prophecies as to the effect of vaccination have so often been falsified.—I am, etc.,

Health Offices, Leicester, Feb. 8th.

C. KILLICK MILLARD.

<sup>1</sup> *Lancet*, November 28th, 1925, p. 1110.

SIR,—On January 14th you published under the title "Fatality rates of small-pox in the vaccinated and unvaccinated" a letter from me containing a tabular statement of small-pox cases and deaths in vaccinated and unvaccinated persons over 15 years of age in England and Wales during the four years 1923–26.

The 13 deaths among 4,010 vaccinated cases gave a case mortality of 0.3 per cent., compared with 4 deaths among 6,915 unvaccinated cases—a case mortality of 0.06 per cent. The fatality among the vaccinated thus appeared to be five times as great as among the unvaccinated—something of a shock for those who, like myself, believe that vaccination, after preventing an attack of small-pox for a number of years, subsequently mitigates the severity of the disease so as to lessen its fatality. I invited explanations from your readers of these obviously absurd statistics, and the answers have been extremely interesting.

A lucid explanation of the statistical anomaly was furnished by Dr. Percy Stocks in your issue of January 21st, and I wish to thank him for his exposure of the fallacy of these so-called "small-pox fatality rates." He shows that the sufferers from "small-pox," whether vaccinated or unvaccinated, were dying at about the same rate as those of the population who were not suffering from "small-pox," and he concludes that "the prevalent mild type of small-pox is not really responsible for increasing the chances of death in persons affected to any measurable degree." This conclusion would be still more obvious and inevitable if allowance were made for the facts that: (a) About half the 17 deaths recorded occurred in small outbreaks of virulent small-pox, and should therefore be excluded in calculating the fatality rate of "mild small-pox" (C. O. Stallybrass, BRITISH MEDICAL JOURNAL, February 11th). (b) The number of missed and unrecorded cases of "mild small-pox" in the four years referred to must have been considerable (but if a "missed case" developed any serious disease or condition and died from it, the chances are that the death would be registered as a death from "small-pox"). (c) Optional vaccination as it exists to-day has made small-pox a class disease. The fatality rate of this class from all causes is probably higher than that of the population as a whole.

Dr. Stocks's interesting analysis of the figures confirms statistically the conclusion I had arrived at clinically—that so-called "mild small-pox" is a non-fatal disease in otherwise healthy individuals. To discuss "small-pox" fatality rates in such figures as 0.3 and 0.06 per cent. is an insult to the very name of "small-pox." I have seen upwards of two thousand cases of this disease in vaccinated and unvaccinated of all ages, with rashes varying from a few spots to almost confluent eruptions, and I have never observed a patient with such a degree of toxæmia as to endanger life, or even to cause the slightest anxiety as to the issue of the illness so far as the "small-pox" itself was concerned. Further, I have had the opportunity of observing the disease through every season of the year for seven successive years, and I have not observed any alterations in its characters at any time during that period, or any tendency to increase or decrease in virulence. It is the same disease to-day as it was when it arrived in these parts in 1921. I believe it is the same disease as Edward Jenner described about a century and a half ago in the following passage:

"About seven years ago a species of small-pox spread through many of the towns and villages of this part of Gloucestershire. It was of so mild a nature that a fatal instance was scarcely ever heard of, and consequently so little dreaded by the lower orders of the community that they scrupled not to hold the same intercourse with each other as if no infectious disease had been present among them. I never saw nor heard of an instance of its being confluent. The most accurate manner, perhaps, in which I can convey an idea of it is by saying that had fifty individuals been taken promiscuously and infected by exposure to this contagion they would have had as mild and light a disease as if they had been inoculated with variolous matter in the usual way. The harmless manner in which it showed itself could not arise from any peculiarity either in the season or the weather, for I watched its progress upward of a year without perceiving any variation in its general appearance. I consider it, then, as a variety of the small-pox."

If this "small-pox" is so mild as to be incapable of causing death, the question naturally arises, "How is it

that a number of deaths have been registered in its name?" The answer is to be found in one word, "nomenclature." According to the rules of death registration, if small-pox and any local disease are mentioned on the death certificate, small-pox is preferred, however the certificate be framed. So long as this rule is in force, and no clear distinction in names is made between the fatal disease small-pox and the non-fatal disease "small-pox," it is obvious that deaths from pneumonia, cerebral haemorrhage, nephritis, and many other diseases which happen to synchronize with an attack of the non-fatal "small-pox" must be registered as deaths from small-pox. The Registrar-General's Department has no choice in the matter so long as it continues to follow this rule. And so it comes about that the non-fatal "small-pox" acquires a purely fictitious fatality rate which is not in any way related to small-pox, and therefore cannot be influenced by the vaccination state of the patients.

To the medical profession the Department of the Registrar-General is one of the greatest scientific assets this country possesses. At the annual autumn dinner of the British Medical Association in 1925 the Registrar-General paid an eloquent tribute to our professional co-operation in the advancement of knowledge, and he finished his speech by affirming that:

"All that the Registrar-General's office did was inspired by an almost fanatical honesty in the desire to furnish nothing which was not trustworthy, nothing capable of misleading, and he thought the profession and the public could rely upon that office not to be moved by any controversial aspect of the material with which it dealt." (Applause.) (BRITISH MEDICAL JOURNAL, SUPPLEMENT, October 31st, 1925, p. 143.)

Those who have not given thought to the supreme scientific importance of correct certification and registration of death should read carefully pages 20 to 33 of the annual report of the chief medical officer of the Ministry of Health for the year 1926. There will be found a brilliant dissertation "on the accuracy of the statement of causes of death," in the last paragraph of which the chief medical officer says:

"These observations have been made to illustrate the great importance of the correct registration of the cause of death. Upon the accuracy of such medical certification much depends. For quite apart from its social and legal value, it is hardly too much to say that the fabric of the art and practice of preventive medicine is founded upon it. The registration of sickness, as far as we can obtain it, is valuable, but the correct ascertainment of the cause of mortality is essential. . . ."

The great majority of toilers in the field of preventive medicine are inspired by an equal zeal for honesty and accuracy in their work, but when it comes to certifying a death from, say, chronic nephritis in a person suffering from an attack of "mild small-pox" all efforts to achieve the truth are balked by nomenclature.

Nomenclature in small-pox thus acquires a vast importance. The present confusion arises from notifying under the one name "small-pox" two diseases which can be distinguished clinically, epidemiologically, immunologically, and statistically, with ease and certainty, as separate entities—namely, small-pox, the severe, virulent, loathsome, and fatal disease, and "small-pox," the relatively trifling, non-fatal disease. This scientific distinction is by no means academic, and the suggestion of a distinctive name for "mild small-pox" is a practical proposition urgently required in the interests of notification, appropriate measures of control, correct death registration, and accurate statistics.

Failure to adopt official nomenclature to our increasing knowledge is bringing discredit upon the art and practice of preventive medicine in general, and in particular is doing more harm to the cause of vaccination than all the efforts of the anti-vaccination societies since their foundation.—I am, etc.,

Health Office, Chesterfield, Feb. 13th.

R. P. GARROW.

## IODINE IN THE TREATMENT AND PREVENTION OF GOITRE.

SIR,—In New Zealand they seem to be satisfied with very homoeopathic doses of iodine—one grain of potassium iodide in 250,000 grains of table salt. We are told (JOURNAL, February 11th, p. 238) that this gives "a margin of safety" against any risk of overdosing. This,

I should think, would be perfectly safe even for a case of exophthalmic goitre. Personally I should have no hesitation in prescribing a grain of potassium iodide daily for a long period, except in cases of hyperthyroidism, but I should hesitate for a long time before I prescribed 571 ounces of Cerebos or Windsor salt daily for anyone. However, this is the age of "safety first," and this experiment can do no harm, but I hope in this country we will not start any such grandmotherly legislation. "The administration of iodine in comparatively large doses to patients in adult life suffering from simple goitre may convert simple goitre into toxic goitre, greatly aggravating the disease." There is no danger of such a catastrophe with iodized salt.—I am, etc.,

London, S.W.1, Feb. 11th.

JAMES BARR.

## OCCCLUSION OF THE CENTRAL RETINAL ARTERY.

SIR,—The memorandum on bilateral embolism of the central retinal artery (BRITISH MEDICAL JOURNAL of February 4th, p. 178) is of great interest, but appears to contain no evidence justifying the restrictive word "embolism." The condition described is retinal occlusion, which may be due to embolism or thrombosis, and I would suggest that the age of the patient (74), the presence of advanced cardio-vascular trouble, and even the consecutive occlusion of the right and left arteries, are much more suggestive of thrombotic causes than of embolism.

These causes are generally accepted, and include endarteritis, arterio-sclerosis, spasm, and failing cardiac efficiency. It is clear that these comprise local determinants as well as general influences, and it is to be remembered that arterio-sclerosis can cause a lowered pressure in the retinal arteries even in the presence of a raised general blood pressure. Spasm is suggested as the likely cause where there have been preceding attacks of transient blindness.

Having regard to all the circumstances paracentesis would appear less hopeful in thrombotic than in embolic cases, but in the latter group particularly it should never be omitted if in time to anticipate retinal death.

I was once fortunate, as a house-man, in being associated with a successful (embolism) case, and found the experience stimulating to future efforts, remembering that, by the laws of chance, we start afresh with each case, unaffected by the general percentage considerations which would be— for paracentesis—so discouraging.—I am, etc.,

Sheffield, Feb. 5th.

E. GORDON MACKIE.

## TREATMENT OF CANCER BY RADIUM.

SIR,—Dr. Fletcher Shaw's experience of the treatment of cancer of the cervix by radium and by operation coincides with my own. Consequently I restrict the use of radium to cases in which the disease appears to be so extensive that radical operation seems to be impossible. The beneficial effect is often pronounced, and in some instances the lesion is improved to such an extent that total removal is practised later. Not one of my cases has been cured by employing radium alone, while many are enjoying good health through having been subjected to the radical operation—some as long as fourteen years ago.—

I am, etc.,

SAMUEL J. CAMERON

Glasgow, Feb. 7th.

SIR,—I had intended my last letter to end this correspondence, but it would be discourteous not to reply to Mr. Hayward Pinch's protest.

By themselves my words are too sweeping, and, taken literally, do an injustice not only to the Radium Institute of London, but also to that of Manchester; but, read in conjunction with the previous correspondence, they can refer only to the want of statistics upon the result of radium treatment of carcinoma of the cervix, after a period of five or more years.

If the London Radium Institute has published such statistics I should be grateful if Mr. Hayward Pinch would direct me to them, and I should be only too happy to apologize to the Institute if I have done it this injustice.—I am, etc.,

Manchester, Feb. 8th.

WILLIAM FLETCHER SHAW.

## UNSUSPECTED VALVULAR DISEASE IN CHILDREN.

SIR,—A considerable amount of attention is now being given to the subject of acute rheumatism in children, and it would therefore be interesting to hear from other readers to what extent valvular disease of the heart occurs without the knowledge of the parents or practitioners.

With an experience gained during the inspection of 20,000 school children I estimate roughly that more than 80 per cent. of the mothers whose children have valvular disease are unaware of the fact until it is pointed out at school inspection.—I am, etc.,

Watford, Herts, Feb. 4th.

JAMES BUCHANAN.

## THE TAVISTOCK CLINIC.

## A Correction.

SIR,—In your issue of February 11th (p. 242) there appears a report of a dinner celebrating the seventh anniversary of the foundation of the Tavistock Clinic for Functional Nervous Disorders, in which I am stated to have expressed myself in these words: "Sir Farquhar Buzzard added that the recently issued report of the clinic for the years 1920-27 was one of the most complete and instructive statements of its kind illustrating the value of psycho-analysis that had yet appeared."

This is not an accurate representation of my remarks. I never used the word "psycho-analysis" in the course of my speech, and my appreciation of the clinic's report referred to its fair-minded, unbiased, yet convincing exposition of the benefits derived from *psychotherapy* by patients suffering from psychoneuroses.

The words of your report suggest that the clinic depends on psycho-analysis for its results and its justification—a suggestion which is likely to do the institution and its appeal for support more harm than good. A perusal of the clinic's report is sufficient to show that psycho-analysis, using the word in its technical (that is, Freudian) sense, is a form of therapy never undertaken by the medical staff, who depend on other psychotherapeutic methods for the successful relief of their patients.—I am, etc.,

London, W.1, Feb. 14th.

E. FARQUHAR BUZZARD.

\* \* We much regret the slip in our news paragraph.

## Obituary.

## GEORGE BALFOUR MARSHALL, M.D.Ed.,

F.R.F.P.S.GLASG.,

Honorary Consulting Gynaecologist to the Glasgow Royal Infirmary and Professor of Obstetrics and Lecturer in Gynaecology to St. Mungo's College, Glasgow.

WE regret to announce the death of Professor G. Balfour Marshall, which took place in a nursing home in Glasgow on January 31st.

George Balfour Marshall was a native of Edinburgh, where his forebears had been prominent in business and municipal affairs for many years. From George Watson's College he proceeded to Edinburgh University, where he graduated M.B., C.M. with honours in 1890. He then commenced preparation for his distinguished career in obstetrics and gynaecology by holding first the appointment of house-surgeon in the Edinburgh Royal Maternity Hospital, then undertaking a long post-graduate course at the Rotunda Hospital, and spending subsequently some three years in Jena and Berlin. From the German schools he brought back a most extensive knowledge of gynaecological pathology, which well-equipped him for the work which lay ahead.

He began to practise in Glasgow in 1893, and in the following year proceeded M.D.Ed. with commendation, and was also admitted to the Fellowship of the Royal Faculty of Physicians and Surgeons of Glasgow. He was appointed to the staff of the gynaecological department of Glasgow Royal Infirmary, where he succeeded the late Dr. Kelly in charge of wards in 1907. He quickly acquired a great reputation as a teacher in the Extra-Mural Medical School, and for many years lectured to crowded classes in the old Western Medical School. He also taught gynaecology at St. Mungo's College, and succeeded Dr. Robert

Jardine as professor of midwifery there in 1921. His clear, witty, and vigorous style of expounding his subject, and the obvious joy he took in inspiring a like enthusiasm in others, rendered him an ideal instructor, whose influence and fame will long survive.

Professor Marshall rendered yeoman service to his professional colleagues. He was for many years a member of the council of the Medical and Dental Defence Union of Scotland, which he was largely responsible for establishing. He represented the Royal Faculty of Physicians and Surgeons of Glasgow on the directorate of the Glasgow Royal Maternity and Women's Hospital. He was a strong supporter of the local Obstetrical and Gynaecological Society, and filled various posts in it, including that of president from 1920 to 1922. He held an appointment from the Privy Council as one of the Government visitors under the Pharmacy Act, and brought to its obligations his characteristic accuracy of observation and whole-hearted interest. He made many valuable contributions to the literature of his specialty. In 1911 he published his well-known *Manual of Obstetrics*, which was based on his lectures and won high praise from medical students and practitioners. His popularity as a teacher owed much to his scrupulous care in observing and recording, and his ability to set out his conclusions attractively and convincingly.

A colleague writes: Dr. Marshall was an admirable surgeon, with splendid judgement and most careful technique. To patients, students, and colleagues he was a model of courtesy and helpfulness, enhanced by a delightful modesty and a kindly, if caustic, wit. He was a most patriotic Scot, with a great love for the Highlands, where he indulged his recreations of fishing and photography, in which he excelled. For several years he suffered from bronchitis and rheumatism, but though suffering even more than usual he lectured to his class at St. Mungo's College on January 20th. On the next day he became acutely ill. An operation revealed an intestinal perforation, and at a lower level there was an inoperable malignant growth. A few hours later he passed peacefully away, having completed a wonderfully full and useful life. His profession and the city where he laboured so devotedly have lost a noble soul. It was only last year that Dr. Marshall celebrated his silver wedding. He leaves a widow and three children. His daughter is a science student in Glasgow University; his elder son has just finished his course at Epsom College, where the younger son now is. The sympathy of the whole profession goes out to the bereaved.

## Medico-Legal.

## ALLEGED NEGLIGENCE AT A MENTAL HOSPITAL.

A SPECIAL jury in the King's Bench Division, after a three days' hearing, awarded Lieut. Commander G. H. Drummond, V.C., R.N.V.R., £150, and Mrs. Drummond £500 damages for alleged negligence and breach of contract against Wonford House Hospital (Incorporated), the proprietors of a mental nursing home in Exeter, but found for the defendants on a counter-claim for £22 10s., the balance of fees.

The alleged negligence and breach of contract consisted in the defendants' nurses not exercising a continuous watch over Mrs. Drummond, who was a patient in the institution. She was watched without cessation until the second night, during which only intermittent visits were paid to her, when, in the absence of the night nurse, she broke the glass of a window and forced herself through an aperture measuring less than ten inches square and through the bars guarding the window, striking an iron balustrade and fracturing her arm and her jaw. After the birth of her third child Mrs. Drummond had become obsessed with the idea that she had committed an unspeakable crime, and had expressed intense dislike for her children and her husband. On the advice of Dr. Grant Wilson she was removed to Wonford House Hospital, and a great deal of evidence given in the case was on the question whether Dr. Grant Wilson told Dr. W. B. Morton, medical superintendent of the hospital, of the suicidal tendencies exhibited by Mrs. Drummond. Dr. Grant Wilson's version of his telephonic communication with Dr. Morton was that he told him Mrs. Drummond was extremely restless and agitated, and she had delusions of persecutions and all the symptoms of acute puerperal

## UNIVERSITY COLLEGE.

SPECIAL short courses in anatomy and physiology, designed to meet the requirements of the Primary Fellowship Examination of the Royal College of Surgeons, are held at University College twice during the session. They are advanced courses intended to supplement the routine instruction required for the professional qualifying examination. Each course extends over a period of three months. The next course will begin on Monday, March 5th, in preparation for the June examination. Particulars of these courses may be obtained from the Secretary of the College.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on February 9th, when the President, Sir Berkeley Moynihan, was in the chair.

## Diplomas.

Diplomas of Membership were granted to 164 candidates, and the Diploma of Fellowship was granted to Mr. H. I. Deitch. Diplomas were granted jointly with the Royal College of Physicians: in Public Health to thirty-six candidates; in Ophthalmic Medicine and Surgery to nineteen candidates.

## Bradshaw Lecture.

The President appointed Mr. C. H. Fänge as Bradshaw Lecturer for the ensuing year.

## International Convention on Cancer.

Sir Berkeley Moynihan and Mr. Steward will attend the International Convention on Cancer, to be held in London from July 16th to 22nd, as delegates from the Royal College of Surgeons.

## Primary Examination for Fellowship in Canada.

A revised scheme for conducting the Primary Examination in Anatomy and Physiology for the Fellowship in Canada was considered and approved, and instructions were given for the scheme to be forwarded to the Canadian Medical Association for their comments.

## Council Election.

An election of four Fellows into the Council will take place on July 5th at 11 a.m. to fill the vacancies caused by the retirement in rotation of Sir Anthony Bowley, Sir D'Arcy Power, and Mr. F. J. Steward, and by the death of Mr. W. Thelwall Thomas. Notice of the election will be given to Fellows by advertisement and by circular on March 9th. March 19th will be the last day for the election.

celebration of the Faculty of Medicine, Cairo, and the International Congress of Tropical Medicine, Cairo, in December, 1928, as a

## ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the College was held on February 7th, when the President, Dr. Robert A. Fleming, was in the chair.

Dr. David Duncan Main, Dr. Charles John Shaw, Dr. Ronald Gray Gordon, and Dr. Thomas Yale Finlay took their seats as Fellows of the College.

Major Annie Chaud, I.M.S., and Dr. James Thomson (Dundee) were elected Fellows of the College.

Dr. David Lees, D.S.O. (Edinburgh), Dr. Premankar De (Calcutta), Dr. Edward R. G. Walker (Aberdeen), Dr. J. D. Allan Gray (Leith), Dr. Donald Ross (Lochgilphhead), Dr. Chas. A. Basker (Bournemouth), Dr. Donald Jack (Edinburgh), and Dr. Alex. H. Rintoul (Kennyway, Fife) were elected members of the College.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

IN the House of Commons this week the debate on the Address in reply to the King's Speech closed on February 14th, and the House carried a motion for the appointment of two new judges. On the previous night the Prime Minister adduced evidence that real wages and the standard of living of the working classes had lately risen in the United Kingdom. The rest of the week in the House of Commons was spent on Supplementary Estimates and private members' business. Neither national health nor any other medical topic was discussed in the debate on the Address.

The Conservative and Unionist Party Committee on Health and Housing had its first meeting of the session on February 14th, and the Parliamentary Medical Committee its first on February 15th, Dr. Fremantle presiding over each.

Dr. Drummond Shiels has returned to the House of Commons from Ceylon, where he has been serving on a special commission.

## Bills before Parliament.

Bills of which notice was given in the House of Commons on February 10th include the Edinburgh Corporation Bill (Substituted Bill) to confer further powers upon the corporation of the city of Edinburgh in relation to venereal disease; the Registration (Births, Deaths, and Marriages) Bill, to amend

the Births and Deaths Registration Acts, 1836 to 1926, presented by Captain Gunston; the Blind Persons Bill, presented by Mr. Naylor; the Dogs Act Amendment Bill, to amend the Dogs Act, 1906, presented by Mr. Briggs; and the Slaughter of Animals (Scotland) Bill, presented by Brigadier-General Charteris and supported by Dr. Shiels. All these were read a first time. Among the bills occupying the ten first places in the ballot for private members' bills—these being the only private members' bills which are likely to become law—none is of direct medical interest.

On February 10th the Secretary for Scotland presented, and the House gave a first reading to, the Reorganization of Offices (Scotland) Bill, which had been promised in the King's Speech. One of its purposes is the transfer of the powers and duties of the Scottish Board of Health to a Department of Health for Scotland.

On February 13th a bill to prohibit the vivisection of dogs was presented by Sir Robert Gower, and was read a first time. The Dogs Act Amendment Bill, introduced by Mr. Briggs, is not an antivivisectionist measure, but will probably propose, among other objects, to strengthen the provisions of the law against the stealing of dogs. The Protection of Dogs Bill, presented by Sir Robert Gower, has as its declared object "to prohibit the vivisection of dogs." It is supported by Colonel Moore, Mr. Bromley, Mr. Macquisten, Mr. Thurtle, Captain A. Evans, Mr. Sexton, and Mr. Radford. The second reading is put down formally for April 20th. Before the presentation of this bill a suggestion was made to its promoters that it might be treated as uncontroversial if a clause were added to authorize the police to supply for experimental purposes dogs seized as strays and subsequently unclaimed. This overture was flatly rejected.

On February 14th Mr. Tinker presented a bill to consolidate, with amendments, the enactments relating to factories, and it was read a first time.

## National Health Insurance.

On February 9th Mr. Chamberlain stated that 355,000 insured persons were estimated to have reached the age of 65 on January 2nd. During the month of January the estimated addition to that number was 8,000. All these would cease to pay contributions under the health insurance scheme and to be entitled to sickness and disablement benefits; medical benefit, together with additional treatment benefits, would remain available to them for life. How many were in receipt of sickness or disablement benefits when they attained the age of 65 was not known.

In an answer to Mr. Feiby, on February 9th, Mr. Chamberlain said the approximate amount of funds invested on behalf of approved societies under the National Health Insurance Act at the end of 1926 was £115,000,000, and at the end of 1927 £111,000,000. In a reply on the same day to Mr. Rhys Davies, Mr. Chamberlain said that after meeting out of current income the cost of schemes of additional benefit, amounting to over £8,000,000 yearly, the approved societies had available for investment in 1926 £1,500,000, and in 1927 £200,000.

## Foot-and-Mouth Disease.

On February 15th Mr. Guinness, replying to Sir Basil Peto, said that in recent years no definite proof had been obtained that foot-and-mouth disease outbreaks in this country had been due to infection by meat imported from South America. Suspicion had, however, arisen that certain outbreaks had been due to cloths in which imported meat was wrapped, or to bones from such meat. To guard against this danger orders had been issued which required meat, bones, or other parts of a carcass, or cloths in which foreign meat had been wrapped, to be boiled or disinfected before they were brought into contact with animals. Negotiations had been in progress for some time with the South American Governments which should result in the adoption in those countries of measures for preventing the introduction of infection into Great Britain.

Mr. Guinness also told Mr. Wardlaw-Milne that he had seen in the press reports of the discovery in France of a new cure for foot-and-mouth disease, but he had no official information on the subject. No invitation had been received by the Ministry to attend the tests. Our policy was eradication by slaughter, and this discovery seemed to be merely a cure and not a preventive.

Mr. Guinness, on February 14th, told Major Davies that no experiments to determine the after-effects on animals which had had foot-and-mouth disease and had recovered from it had as yet been carried out by the Foot-and-Mouth Disease Research Committee. There was considerable evidence from abroad that the after-effects of the disease were variable. Mortality among unweaned stock was very high. The Continental view was that a certain proportion of the recovered animals became "carriers" of the disease, and were for a long time capable of infecting susceptible stock.

**Milk Campaign.**—Mr. Guinness announced, on February 9th, that the Empire Marketing Board, in consultation with the Ministry of Agriculture, proposed to open, in April, a publicity campaign in favour of the consumption of fresh milk. This campaign will

last for six months, and may be extended. Dr. Drummond Shiels asked whether the Minister would see that this advocacy of fresh milk discriminated between tuberculosis-free milk and other milk which might be dangerous. Mr. Guinness said the proportion of tuberculous milk was much lower than a few years ago. He thought nothing more could be done than was being done at present to improve the supply of milk and avoid this danger. Dr. Fremantle asked whether the Minister of Agriculture proposed in this publicity campaign to work with the Ministry of Health, which was able to use the medical channels for recommending milk. Mr. Guinness said they would certainly work in conjunction with the Ministry of Health.

**Marriage of the Physically Unfit.**—On February 13th Sir R. Thomas asked the Minister of Health if he had devoted any attention to the report on the marriage of the physically unfit, recently issued by the London County Council, and if he proposed to introduce legislation on the subject. Sir Kingsley Wood said the Minister of Health was not aware of the adoption of any such report by the London County Council.

**Prohibition of Boric Acid in Cream.**—Sir J. Gilmour told Brigadier-General Charteris, on February 14th, that only a few creameries in Scotland had made representations against the prohibition of boric acid in cream. There was substantial evidence that cream properly produced from clean milk and properly handled would keep sweet for several days. The Scottish Board of Health accordingly saw no reason to rescind the regulations so far as they applied to cream.

**Hours of Railway Dining-car Attendants.**—On February 14th Mr. Belterton, in reply to Sir R. Thomas, said he was informed by the Great Western, London, Midland, and Scottish, and London and North-Eastern railway companies that there was no foundation for the statement that railway dining-car attendants were habitually required to be on the trains for periods up to forty-eight or fifty-three hours, with consequent tuberculosis and gastric disorders.

**Proposed New Welfare Centre at Southgate.**—On February 14th Mr. R. Morrison asked why the Minister of Health refused to approve or make a grant in aid of expenditure by the Southgate Urban District Council of £19, the salary of the medical officer, in respect of a proposed new maternity and child welfare centre to be held on premises belonging to the council for two hours monthly, for medical inspection of children between the ages of 2 and 5 years. Sir Kingsley Wood, replying, said that sanction to this proposal was withheld because the Minister of Health was advised that the facilities already provided by the urban district council should be sufficient to allow of the medical inspection of children between the ages of 2 and 5 years. It was proposed, however, to arrange for a further inspection by a medical officer of the Ministry of the arrangements made by the council for maternity and child welfare, and the Minister would give further consideration to this proposal when he had received a report on this inspection.

**Street Accidents.**—In the House of Lords, on February 14th, the Bishop of Southwark called attention to the statement of the education officer of the London County Council that in 1926 in the Metropolitan area 233 children were killed and 9,528 were injured by traffic accidents. Lord Peel, First Commissioner of Works, in reply, said that the Advisory Committee on Street Accidents, appointed by the Minister of Transport, had presented a report about a year ago. The committee was set up because of the anxiety of the Ministry of Transport to see what could be done to reduce the dangers of the streets. He understood that the Advisory Committee would report very soon to the Ministry. The Minister of Transport was prepared to give a special direction to the committee to consider particularly the problem of accident. He would consult representatives of the police and local authorities, and might decide upon definite rules to reduce these accidents.

**Memorial to Lord Haig.**—On February 8th Mr. Baldwin moved that the House, on the following day, go into committee to pass an Address for the erection of a monument at the public charge to the late Field-Marshal Earl Haig. Mr. Ramsay MacDonald moved as an amendment that a select committee be appointed to consider the most fitting form of memorial to Earl Haig, in view of his concern for the comfort and welfare of ex-service men. Supporting the amendment, Dr. Drummond Shiels said there were many tuberculous ex-service men who were gassed during the war and whose disease did not make itself known for many years. Many of these cases had been disallowed. The House had an opportunity to make up for what it had failed to do in the past. The amendment was defeated by 220 to 103, and later in the week the House unanimously passed the Address in favour of a monument.

#### Notes in Brief.

The Minister of Pensions has discussed with a deputation from the Glasgow Corporation the future of Bellahouston Hospital.

There is no evidence to show that the tsetse fly is increasing or spreading anywhere in Kenya Colony.

Local authorities are increasingly making use of dust carts with covers, and are encouraged by the Ministry of Health to do so.

During 1927, out of 53,915 men and boys who offered themselves for service in the Royal Navy and Royal Marines, 5,655 were accepted and 47,866 rejected for medical, physical, and educational unfitness.

## Medical News.

THE annual dinner of past and present students of the Royal London Ophthalmic (Moorfields Eye) Hospital was held at the Langham Hotel on February 8th, with Sir Whitton Herringham in the chair. Among the guests were Sir John Rose Bradford, Sir James Berry, Surgeon Vice-Admiral Arthur Gaskell, Sir Mathew Fell, Professors Elliot-Smith and H. Hartridge, and Messrs. Ernest Clarke and Theodore Lining. The toasts were proposed by the chairman, Sir John Parsons, and Sir William Lister. During the evening the dean, Mr. Charles Goulden, announced that 123 new students had enrolled; the number attending the practice of the hospital was 215. Two students had received the diploma of F.R.C.S.Ed. in ophthalmology. The first part of the examination for the diploma in ophthalmic medicine and surgery had been passed by twenty-eight students and the second part by twenty-six. During the past year Dr. H. M. Traquair of Edinburgh had given a course of lectures on perimetry and fields of vision, and two lectures on the resolving power of the eye. In the coming term Professor Elliot-Smith would give a course of six lectures on the optic connexions in the brain, and Dr. Kerr, late principal school medical officer of the London County Council, two lectures relating to education of the partially sighted.

THE Council of the Haveland Society of London has chosen for the Buckston Browne Prize the subject "Chronic streptococcal illnesses"; a medal, together with the sum of £20, will be awarded for the best essay on this. The prize is open to any member of the medical profession registered in the British Isles or Dominions under the age of 45. Essays must be sent in by November 1st, 1929. Further particulars may be obtained from the honorary treasurer, Dr. G. A. B. Turtle, 81, Cambridge Terrace, Hyde Park, W.2.

AT the next meeting of the Royal Statistical Society on February 21st Dr. T. H. C. Stevenson will read a paper on the vital statistics of wealth and poverty. This will include a discussion of the social distribution of various causes of mortality. The meeting will be held in the hall of the Royal Society of Arts, John Street, Adelphi, W.C.2, at 5.15 p.m.

THE jubilee of the Caledonian Medical Society will be celebrated in Edinburgh on February 23rd and 24th, under the joint presidency of Dr. W. A. Macnaghten and Dr. S. Rutherford Macphail, the two surviving founders. The jubilee dinner will take place in the Hall of the Royal College of Physicians, Queen Street, at 7.15, on February 23rd. The annual meeting will be held at the Royal College of Surgeons' Hall, Nicolson Street, at 11 a.m. on February 24th, while at 4 p.m. on the same day the University of Edinburgh is giving a reception for the society.

Dr. A. F. TREDGOLD will lecture for the Fellowship of Medicine on the nature of mental deficiency at the Medical Society, 11, Chandos Street, Cavendish Square, on February 20th, at 5 p.m. On February 21st, at 3 p.m., the dean of the London Lock Hospital will give a clinical demonstration, limited to twelve; applications to be made to the Fellowship of Medicine (telephone Mayfair 2235). A lecture-demonstration on cornual ulcers and their treatment will be given on February 23rd at 5 p.m. On February 24th a clinical demonstration will be held at St. James' Hospital, Vanxhall Bridge Road, at 3 p.m. The lecture and demonstration are free to medical practitioners. A four weeks' course in venereal disease will be undertaken by the London Lock Hospital from February 20th to March 16th, consisting of clinical instruction with a series of lectures. There will be an intensive course at the Queen Mary's Hospital, Stratford, from February 20th to March 3rd, with lecture, demonstration, and operations throughout the day, and a one-week course at the Maudsley Hospital, S.E.5. A week's course will be given at the Brompton Hospital from March 19th to 24th; a two weeks' course in diseases of children at the Queen's Hospital from March 5th to 17th; and two weeks' courses in gynaecology at the Chelsea Hospital from March 5th to 15th, and in ophthalmology at the Royal Eye Hospital (afternoon only) from March 5th to 17th, including Saturdays. For general practitioners a late afternoon course (4.30 to 6 p.m.) has been arranged at the Hampstead General Hospital. All information as to syllabuses and fees, with particulars of the general course, may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE Royal Society announces in our advertisement columns that applications for the Government grant for scientific investigations for 1928, on printed forms to be obtained from the clerk to the Government Grant Committee, Royal Society, Burlington House, W.1, must be received by March 31st.

THE centenary celebration of the faculty of medicine at Cairo and an international congress of tropical medicine and hygiene will be held in association from December 15th to 22nd, 1928, in that town. In the provisional programme, which has just been issued, it is stated that various sectional meetings will be held and that special attention will be paid to ankylostomiasis and bilharziasis. The proceedings of the congress will be published. In connexion with this celebration a medical exhibition is being arranged, and it is possible that the foundation stone will be laid of a new building to replace the existing Kasr-el-Ani Hospital. Further information may be obtained from the general secretary, Dr. M. Khalil, 1, Sharia Mazloum Pasha, Cairo. The postponed congress known as the Journées Médicales d'Égypte will be held at Cairo from December 12th to the 23rd on the lines of the original programme, which were mentioned on October 15th, 1927 (p. 711). Further details of the congress and the excursions to Luxor and Assouan may be obtained from the general secretary, Dr. Zoltoun, 32, Rue Gay-Lussac, Paris (V\*).

UNDER an Act recently passed in the State of Victoria (Australia) the registration of British dentists is restricted solely to licentiates of British medical authorities, and the restrictions apply to all dentists who had not embarked for Victoria prior to December 8th, 1927.

THE January issue of *The Fight Against Disease*, the quarterly journal of the Research Defence Society, contains a reprint of an article in *Science* on January 14th, 1927, by Dr. W. W. Keen, on the early days of antivivisection. Some recent correspondence in the lay press on small-pox in England and antivivisection propaganda is reprinted. Sir Leonard Rogers contributes a note on the increase of small-pox in England since 1920, and illustrates this with a chart. It is announced that the membership of the society is steadily growing; the subscription for members is 10s., associate members pay 5s., and undergraduates and students of medicine 2s. 6d. Further information may be obtained from the secretary at the office of the society, 11, Chandos Street, W.1.

ON his retirement, after practising for twenty-seven years in Crieff, Dr. D. Robertson Dobbo was presented by his colleagues and friends with a parting gift of a wallet of Treasury notes. He was honorary medical officer to Crieff Cottage Hospital, and had had twenty-five years' service in the R.A.M.C.

THE Universities Bureau of the British Empire, 50, Russell Square, W.C.1, has published a classified list of students from other countries who are studying in the universities and university colleges of Great Britain and Ireland. A total of 4,875 names is included; of these 1,826 come from Asia, 1,101 from Africa, 887 from America, 693 from Europe, and 362 from Australia, New Zealand, and Fiji. The price of the list is 1s.

THE rank of officer of the Legion of Honour has been conferred on Dr. Pierre Fradet, a well-known Paris surgeon and senior medical officer of the Paris, Lyons, and Mediterranean Railway; Dr. Loeper, professor of therapeutics in the Paris faculty of medicine; Dr. Abadie, professor of nervous and mental diseases at Bordeaux; and Professor Léon Blum of Strasbourg.

DR. JEANDELIZE has been nominated professor of ophthalmology, and Dr. Jacques Parisot professor of hygiene and preventive medicine, in the Nancy faculty of medicine.

A SPECIAL number of *Acta psychiatrica et neurologica* has been dedicated to Professor Viggo Christensen of Copenhagen by his friends and pupils on the occasion of his sixtieth birthday.

PROFESSOR CLEMENS FIRQUET of Vienna has been elected president of the International Union of Child Welfare in succession to the Duke of Atholl.

DR. I. A. ABT, professor of pediatrics of the North-Western University Medical School, Chicago, and editor of a system of pediatrics, has recently been appointed an officer of the Legion of Honour.

DR. R. M. APPERT, who recently died at San Remo at the age of 65, has bequeathed the Institut Pasteur of Paris a sum of 2,000,000 francs.

PROFESSOR EDUARD REHN of Düsseldorf has been nominated successor of Professor Garré in the chair of surgery at Bonn University, and Dr. Sigurd of Freiburg has succeeded Professor Trendelenburg in the chair of pharmacology at Berlin.

OF 420 cases of tularaemia reported to the Public Health Service of the United States 17 patients have died, a mortality of about 4 per cent. The actual number of cases and deaths is probably higher. Cases have now been reported from Japan, the District of Columbia, and from thirty-seven States, the nine North-Eastern States being the only significant portion of the United States in which cases have not been recognized.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notices to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9561, 9562, 9563, and 9564** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Antilog Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

### QUERIES AND ANSWERS.

#### FUMES OF TAR.

DR. J. H. DUDGEON (Stainburn, near Workington) asks for information about the action of the fumes on those working with tar. He has seen cases of the most acute abdominal pains, lasting for days; relief was only obtained by large doses of aperients; x-ray examinations revealed no abnormality. Dr. Dudgeon asks also for references to any literature bearing on the subject.

\* \* We have referred this inquiry to Sir Thomas Oliver, who writes: Tar fumes act particularly upon the skin, leading to acne or the formation of small pustules, with considerable irritation; they also act upon the respiratory mucous membrane, inducing bronchitis. Not an infrequent result is epitheliomatous ulceration of the skin. Of the effects of tar vapours upon the alimentary canal, little is known beyond loss of appetite, nausea, headache, and, in some instances, diarrhoea. Nothing of an authoritative nature has been published bearing upon the relationship of acute abdominal pain and the inhalation of tar fumes. Reference to the subject may be obtained by consulting the brochures on "Occupation and health" which are being issued by the Industrial Section of the League of Nations.

#### CLEANING DENTURES.

DR. JOHN FLETCHER (London, S.W.) writes: A strong solution of "harpic" will, in one night, remove the thickest deposit of carbon, with the aid of a stiff brush in the morning.

#### PAINLESS NATURAL LABOUR.

DR. HOWARD G. PISEL (Maidstone) writes: I remember having a similar case to those described by your correspondents many years ago now. The patient was a young primipara, who assured me that her uterine contractions caused no pain at all. Her mother, a multipara, was present at the confinement. She told me that her confinements also were painless, and added that she "would sooner have a baby than a 'poorly time' any day"! If true, this certainly seems curious.

#### FIREMEN'S CRAMP.

"SHIP" writes: I should be interested to have your readers' views as to the etiology and treatment of "firemen's cramp." It is on board supposed to be brought on by the drinking of much iced water. This may account for the cramp, which takes the form of abdominal colic, but is not necessarily the cause of that which affects the somatic muscles. I recently did several four-hour watches in the stovehold in the tropics. I drank very little iced water indeed, but though I had no "cramps" while on watch, I subsequently suffered from them, but only in leg and arm muscles, when these were mildly strained in action. Fatigue and loss of fluid by sweating, etc., presumably account in part for this form of cramp, which I had hoped to escape by drinking while on watch well-sweetened, non-iced maté. Considering the frequency with which firemen—and not only novices and beer drinkers—are affected with agonizing "cramps," some hints as to treatment would be very welcome.

#### INCOME TAX.

##### *Surgery Expenses.*

"J. H. S." has succeeded to a share in a practice. For a time the practice rented surgery accommodation from his predecessor's widow at £50 per annum—the amount formerly allowed as a reasonable proportion of the predecessor's total expense of rent,

rates, domestic service, etc. Fresh arrangements became necessary, and "J. H. S." has had to find a new residence large enough to provide the necessary surgery accommodation. His total expenditure is about £220 per annum, and his partner agrees to his charging £110 to the firm's account. Will this be permissible for income tax purposes?

\* \* On this question the only safe rule is that the charge must be reasonable in the circumstances of the particular case. For instance, "J. H. S." mentions that before removing into his present house his expenses were less than half what they are now; but is it not true also that he has better domestic accommodation and greater amenity than formerly? Further, one-half the total cost of domestic service seems *prima facie* rather a heavy charge against the surgery, in view of the probable division of the maid's working time. We can only suggest such points for consideration, and may perhaps add that for income tax purposes "J. H. S." would be on safer ground in claiming, say, one-half rent and rates and one-third of the other general expenses of the house.

#### Cash Basis.

"R. B. S." in 1926 purchased a half-share in a practice, his present partner purchasing the other half. They now wish to continue to be assessed on the basis of cash receipts, being willing to bring into the account the amount of the payments made to the old firm, as well as those made to "R. B. S." in respect of his former practice. The inspector of taxes demurs to that, claiming to base the assessment on the amount of book debts earned in the year, but allowing one-third of the outstanding debts as probably irrecoverable. Presumably the one-third is to cover the 12½ per cent. commission paid for collecting debts, and on that assumption is considered insufficient.

\* \* The question depends so much on local conditions that it is impossible to offer specific advice as to the percentage to be taken as representing irrecoverable debts. But if "R. B. S." has—as presumably he has—access to the books of the old firm, it might be possible to prepare a tabular statement for, say, the past six years setting out the comparison between book debts and cash receipts; if those figures suggested any fairly definite percentage it would only leave to be taken into account any special circumstances of the present time. Another alternative would be to request the inspector—or the District Commissioners if the matter is taken to appeal—to leave the disputed margin—namely, the difference between 50 per cent. and 33½ per cent. of the outstanding debts—in abeyance for twelve months. At the end of that time it might be possible, in the light of the additional information then available, to arrive at agreement.

### LETTERS, NOTES, ETC.

#### PHYSIOLOGY OF DEFAECATION.

DR. JAMES R. WHITWELL (London, S.W.) writes: With reference to the letter of Dr. Fraser-Harris (*JOURNAL*, February 4th, p. 199), I had put into my house many years ago an excellent water-closet, which admitted of the normal attitude, called the "Health," made by Messrs. Doulton and Co. This is, I believe, still made, but is somewhat handicapped by its higher cost.

DR. ALFRED C. JORDAN (London, W.) also writes on the subject of the "Health" closet, with low, sloping seat, made by Messrs. Doulton. Although introduced some years ago (he says) this did not "take on" because it was found that many people, expecting the usual high seat, came down with a bump on the low one. Moreover, sanitary engineers have told me that a seat low enough to permit the correct "squatting" posture leaves no room for a "trap" between basin and floor. A very useful expedient is the foot-rest made by the P.A.F.R. Company of Newark-on-Trent. This foot-rest allows of the correct squatting posture, is inexpensive, and can be installed in any closet in a few minutes. It is a notable aid to defaecation and a most helpful appliance.

#### A SURGICAL EMERGENCY IN THE MISSION FIELD.

COLONEL A. FENTON, I.M.S. (Burma), forwards an interesting note by Mr. J. O. Wilson, field missionary secretary of the Adventist Mission in Burma, of a surgical emergency successfully dealt with in a remote region of the country. A young man was gored by an elephant, the abdominal wall being torn across, with extrusion of the intestines. These were wrapped in a dirty garment and the man brought by canoe to the hospital, exposed to the tropical sun for the whole of one afternoon. Two lay Australian missionaries administered an anaesthetic, cleansed the intestines and stitched up the wound. The patient, with much hope of the patient surviving, the pus followed, the wound being infected. There was very little rise of temperature and no signs of peritonitis. The muscles had, however, been badly bruised by the blunt tasks of the elephant, and the necrosed tissues sloughed away in three or four days, together with the stitches, so that the wound had to be sewn up again. The patient, however, recovered in two months.

#### VITAMINS IN VERSE.

A FORTNIGHT ago we quoted, in the course of an article on biochemical products, one stanza from a witty and ingenious poem, "The A B C of Vitamins," which appeared in the January issue of the *St. Bartholomew's Hospital Journal*. So far from incurring blame for introducing light verse, however apt, into a serious discussion, we have had a number of requests to reprint the poem in full. Some readers wish for it as *memoria technica*, because they find difficulty in recalling offhand the properties of the several vitamins. Impressed with this argument, we have approached the editor of our contemporary, and he and his gifted contributor, "C. H. A." have courteously given their assent to republication of the verses for the enjoyment of a wider circle.

#### THE A B C OF VITAMINS.

A.

Oh fine and fat was Ralph the rat,  
And his eye was a clear cold grey.  
How mournful that he ate less fat  
As day succeeded day,  
Till he found each cornea daily hornier,  
Lacking its Vitamin A.

"I missed my Vitamin A, my dears,"  
That rat was heard to say.  
"And you'll find your eyes will keratinise  
If you miss your Vitamin A."

B.

Now polished rice is extremely nice  
At a high suburban tea,  
But Arlathnot Lane remarks with pain  
That it lacks all Vitamin B,  
And heri-beri is very very  
Hard on the nerves, says he.

"Oh take your Vitamin B, my dears!"  
I heard that surgeon say;  
"If I hadn't been fed on standard bread,  
I shouldn't be here to-day."

C.

The scurvy flew through the schooner's crew  
As they sailed on an Arctic sea.  
They were far from land and their food was canned,  
So they got no Vitamin C.  
For "Devil's use of orange juice,"  
The skipper had said, said he.

They were victualled with pickled pork, my dears,  
These mariners bold and free.  
Yet life's but brief on the best corned beef  
If you don't get Vitamin C.

D.

Though its price we find a trifle high,  
I am sure you'll like it well,  
For it's rich in Vitamin D,  
Though its price we find a trifle high,  
Or our ultra-violet light.

So swallow your cod-liver oil, my dears,  
And bonny big babes you'll be.  
Though it makes you sick it's a cure for the rickets  
And teeming with Vitamin D.

E.

Now Vitamins D and A, B and C  
Will ensure that you're happy and strong;  
But that's no use; you must reproduce  
Or the race won't last for long.  
So Vitamin E is the stuff for me,  
And its praises end my song.

We'll double the birth-rate yet, my dears,  
If we all eat Vitamin E.  
We can blast the hopes of Maria Stopes  
By taking it with our tea.

C. H. A.

Our earlier quotation of stanza D has brought us a rendering of it from Mr. William Holloway which may please medical men who have preserved their taste for elegiacs. It runs:

Namque igitur vitam vitam quod instat abest.  
Si "D" Vitamin, vita quod instat abest.  
Etsi oleo jecorum insidias frustivimus ejus,  
Luceque quam violae, caeruleo ferit.

#### LOBAR PNEUMONIA WITH DIPHTHERIA AND MALARIA.

DR. S. K. CHAUDHURI (Benares) writes to report the case of a lad, aged 17, who developed the usual signs and symptoms of lobar pneumonia, with typical sputum. On the fifth day a greyish patch was found on the soft palate and diphtheria bacilli were demonstrated in it. Injections of antidiphtherial serum were given to a total of 40,000 units and the recovery was uneventful, except for a rise of temperature in the fourth week, due to malaria, which also yielded to suitable treatment.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 48, 49, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.  
A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 66.

# A British Medical Association Lecture ON CHRONIC MUSCULAR RHEUMATISM AND PANNICULITIS.

DELIVERED TO THE SOUTHPORT DIVISION

BY

RALPH STOCKMAN, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, UNIVERSITY OF GLASGOW.

CHRONIC rheumatic diseases are, generally speaking, of microbe origin, and can usually be traced back to a preceding attack of acute rheumatism, influenza, dysentery, or some other infection, and hence they may be due to a considerable variety of germs. But whatever the original infection may have been, the basic pathological change which is the cause of the symptoms and sufferings of the patient once he has become the victim of what we designate "chronic rheumatism" is in all cases the same, and consists in a low form of inflammation of the white fibrous tissues which constitute so large and important a part of the locomotory system of the body—namely, the aponeuroses, sheaths and fibrous origins and insertions of muscles, periosteum, the innumerable ligaments of joints and their synovial membranes, fasciae, nerve sheaths, and the subcutaneous areolar tissue. Fibrosis of the internal viscera and arterial system is not a feature of chronic rheumatic conditions. In acute rheumatism, on the other hand, carditis and valvulitis—both inflammations of fibrous tissue—are very common, whereas in gonorrhoeal, searlatinal, and other so-called rheumatisms they may fairly be described as rare, although their occasional occurrence is quite well recognized. These differences in the incidence of infection are difficult to explain, but they are of very considerable clinical interest and importance.

Chronic rheumatism, then, is essentially a fibrositis of the locomotory system—the *habitus externus* of older writers, as opposed to the internal organs—and, as fibrous tissue is so widely spread, it may affect many regions of the body, or may be confined to one or a few parts; but whatever its situation or whatever name it may go by—lumbago, pleurodynia, sciatica, torticollis, coxalgia—it has always the same pathology. The fibrositic tissue is a local reaction to an irritant, and is therefore a sequel rather than a primary disease, just as valvular heart disease or fibroid lung are sequels to an acute rheumatic or a tuberculous infection and once established they remain permanently, and may ultimately give rise to serious troubles of a totally different character long after the original infection which caused them has died out.

As time does not permit a survey of the whole ground, I propose to confine my remarks to the two commonest manifestations of fibrositis—namely, chronic muscular rheumatism and panniculitis—because they furnish the great bulk of cases seen in practice, they give rise to a vast amount of chronic ill health and disability, and, relatively speaking, they are fairly amenable to treatment if it is founded on a knowledge of their pathology and intelligently carried out.

## CHRONIC MUSCULAR RHEUMATISM.

The morbid anatomy is simple enough. As the result of local infection or local irritation spreading more or less widely from some centre or focus elsewhere in the body serous exudation takes place in small patches of fibrous tissue; these swell up and become painful, active proliferation and formation of numerous fibroblasts occur, and there is an overgrowth of the fibrous tissue of the local nerve twigs and minute blood vessels. The two last seem to me to be of importance in determining the typical symptoms of chronic rheumatism, the inflamed nerves being responsible for the pain, and the inflamed injured vessels for

the subsequent great liability of these lesions to exudation of serum and swelling from slight causes. When first formed the inflamed patches are soft and consist of a good deal of undifferentiated matrix, but as time goes on they become much harder in consistence and very definitely fibrous. On palpation through the skin they can usually be readily felt, and their tenderness on pressure is a further and useful aid to locating them.

The pathological fibrous tissue differs from the healthy normal in being painful on pressure, in being very sensitive to irritation, in a tendency to contract, and in the fact that it can be dispersed by massage or absorbed by the *vis medicatrix naturae*. Its formation is a local reaction to the virus of certain infections, among which acute rheumatism, influenza, tonsillitis, rheumatoid arthritis, mucous colitis, gonorrhoeal septicaemia, dysentery, and coliform infection are common and definitely known, although there are probably others not so easily traceable. In many cases it starts at an early age in life. Chemical poisons such as lead, arsenic, and alcohol, which are notorious as causes of neuritis, do not give rise to a more general fibrositis such as we are considering, nor in my experience do *vaguo streptococci* and *staphylococci*, although they have often been accused. The original infection may disappear, leaving behind it a legacy in the shape of the new pathological fibrous tissue, or it may persist in a more or less latent condition (as is so fully recognized with tubercle and syphilis) and insidiously keep up and increase the fibrositis, so that with increase of years there is continuous increase of rheumatism. Scar tissue formed during suppuration, adhesions, and pelvic cellulitis have the same origin and pathology, and may be equally productive of symptoms. But microbe infection does not seem to be a necessary factor. Sprains of muscles and joints, accompanied by tearing of the tissues with exudation of serum and blood, are often followed by formation of new pathological fibrous tissue, and the consequent pain, weakness, and disability may be very persistent or even lifelong.

As has been previously mentioned the new inflamed fibrous tissue is very susceptible to many and diverse forms of irritation hardly felt by the healthy individual, and hence unwonted muscular exertion, exposure to cold and wet, keen winds, moist heat, changes in barometric pressure, slight infections, and intestinal fermentation are apt to cause serous exudation; the exudation is not readily got rid of by the thickened capillaries, it exerts pressure on the inflamed nerves, and a "rheumatic attack" is the result. In a changeable climate with continual barometric variations some people are thus never free from more or less rheumatic pain, although an anticyclone with high pressure and dryness of the atmosphere may give them some temporary relief at times. The disturbing influence may have a general effect on all the rheumatic tissue throughout the body, or it may be confined to a single area, as is seen in an attack of lumbago after undue use of the lumbar muscles or of torticollis after exposure to a draught.

The morbid anatomy explains the familiar symptoms. Aching, weariness, and pain are all different degrees of the same symptom and are due to the neuritis, while the stiffness is due to stagnation of the circulation and exuded serum. Thus the stiffness so often felt in rheumatic tissues after resting arises from the latter cause, and tends to disappear as soon as a little active movement has improved the local circulation. The symptoms of pain and stiffness are most often complained of in parts liable to muscular strain and to exposure, such as the small of the back, lower limbs, neck, and shoulders, but the abdomen and inner aspects of the thighs may show equal abundance of rheumatic tissue, although they do not suffer so much owing to being less exposed to strain and external influences. They are often, however, just as tender on pressure or if they do happen to be exercised.

During an acute exacerbation with pains all over the body the patient should remain in bed for two or three days and be treated on general principles with mild analgesics and diaphoretics—Dover's powder, salicylic compounds, phenazone and similarly acting substances, hot baths, and so on. If the attack be confined to a small

area—say a torticollis—massage is most helpful in addition to the usual liniments, poultices, and other local applications. Its object is to get rid of the exudation and improve the circulation in the inflamed area, and hence it should be begun as early as possible and given as effleurage firmly and deeply, but short of increasing the irritation and pain.

Before starting on a prolonged course of treatment designed to reduce or get rid of the fibrositic tissue it is absolutely essential that a strenuous effort should be made to deal as effectively as possible with diseased tensils, gonococcal foci, chronic dysentery, colitis, and other known predecessors of fibrositis. Unfortunately eradication of these is not always possible, and as long as they are present they remain sources of rheumatic fibrosis, and a permanent cure of the latter is also impossible. In certain of these cases protein shock therapy is worth considering. Many patients, however, seem to have got rid of the original infection, leaving only the fibrositis to be treated, and this is a very practicable matter. There is no known drug which will bring about absorption of fibrous tissue, and hence for relief or cure of the chronic thickenings massage is our great *mainstay*, but it must be applied with a definite knowledge of what it is desired to accomplish. We wish to get rid of the exudation and the neuritis, and, if possible, to break up and disperse the little areas of new fibrous tissue, which is a much more tedious and difficult matter. A lubricant, such as oil, liquid paraffin, or vaseline, should be freely used, and the efficacy of the massage is greatly increased by the previous application of heat and moisture or dry hot air. For the first ten days or so gentle but firm and efficient effleurage should be given daily for about ten minutes to each part which is being treated. At the end of that time the local soft swelling and exudation have been got rid of, the neuritis is lessened, and the fibrous thickenings can usually be felt as more defined, somewhat hard and sensitive little masses which gradually become insensitve to the pain of the massage, which should then be given as hard as it can reasonably be borne by the patient, and applied specially to the small thickened painful areas. Light massage is valueless at this stage. Recent indurations clear up in three to five weeks, but the more fibrous and those of long standing take a very much longer time, and may never become broken down and absorbed. These last remain rheumatic subjects, and may require a few weeks' treatment once or twice yearly to keep them free, or comparatively free, from symptoms. Such patients should be taught to massage themselves, or get the assistance of some member of the household to do it. It is not difficult to learn. The treatment is always tedious and expensive, but so far it is the only means known of dispersing the rheumatic fibrous tissue. Ionization, diathermy, electricity, radiant heat, and such measures merely relieve the exudation and swelling, leaving the new fibrous tissue *in statu quo* and liable to become again acutely inflamed on the first opportunity. In the same way spa treatment by hot baths, purgation, diaphoresis, and diuresis temporarily removes the congestion and pain and stiffness.

In treating sciatica it should be borne in mind that it is most often due to rheumatic thickenings in the hip—not necessarily on the nerve itself, but involving one of its branches—and in the same way the cause of brachialgia is to be sought for in the deltoid, trapezius, and infraspinatus muscles chiefly. The pain seems to be reflected down the large nerve from pressure on the branch. In lumbago and torticollis the fibrositis may be widespread locally, or there may be only one or two very sensitive nodules from which the pain radiates widely, and in that case treatment should be concentrated on these. Fibrous nodules are not uncommon in the heel, and sometimes give rise to much pain and consequent lameness. These cannot be dispersed by massage owing to the thickness of the sole and their hardness. The only method of cure is to reflect the skin and remove the fibro-fatty tissue *en masse*, the result being invariably satisfactory.

Rheumatic headaches due to perineuritis of the temporal, supraorbital, or occipital nerves are best treated by blisters over the part where the nerve comes to the surface, and where it is usually found to be very tender on pressure.

Once the rheumatic thickenings have been dispersed or lessened under treatment an active outdoor muscular life should be led as far as is reasonably possible for the individual. He thus becomes hardened, and muscular exercise, draughts, and other slight causes of irritation cease to trouble him.

#### PANNICULITIS.

Panniculitis is a fibrositis of the panniculus adiposus, and has the same etiology and pathology as fibrositis generally. Its anatomical distribution, however, confers on it certain clinical characteristics which merit some special description. The new fibrotic tissue assumes two forms, according to its situation. Over the deltoids, shoulders, back, flanks, upper abdomen, hips, and outer sides of the thighs it is dense and evenly spread, giving the skin a hard brawny feel, while on the inner surfaces of the upper arms and thighs, abdomen, and pectoral regions it is in numerous pen-like masses lying in the subcutaneous fat and often forming veritable fibro-fatty pads at the inner sides of the knees and elsewhere. The little masses can be easily felt, and are exceedingly tender on pressure, as is likewise the whole subcutaneous overgrowth. Sometimes distinct encapsulated lipomata are found, and these have a core of inflamed fibrous tissue, as if the local irritation had determined their growth.

It is an extremely common condition in all degrees of severity in women of all ages, but is also found not infrequently in men, and in boys and girls. It seldom, however, takes on the same proportions in men as in women, and this seems to be connected with the much greater development of the panniculus adiposus in the latter. These patients, when the condition has become well advanced, complain of a constant sense of fatigue, dull or acute pains, stiffness, numb feelings, neuralgic headaches, and very often are distinctly neurasthenic. The skin bruises very readily, backache is often present, the weight of a coat tires the shoulders, and even the pressure of lying in bed may be painful. If from any cause an acute exacerbation of the whole fibrositic area occurs all the symptoms are intensified and may remain so for a week or more, often of severe suffering. Some of these people are not stout, but obesity greatly increases the symptoms and sufferings, and as so many women over 30, and particularly after the menopause, tend to lay on fat, medical advice is usually first sought at this time. Most of them, however, give a history of having been more or less "rheumatic" for years previously. There may be great increase of bulk all over the body, or it may be only round the lower abdominal regions, but the thighs, upper arms, and shoulders also rarely escape. The whole abdomen may be bulky, heavy, and pendulous, or may have several transverse folds of softer fibro-fatty tissue lying like cables across it. The new tissue may be chiefly of the dense hard kind, or of the fibro-fatty, or, most commonly, a mixture of the two. In a number of these cases, as time goes on, the irritant, whatever it may be, tends to affect at certain places the synovial membranes and the periosteum (both fibrous structures); the former hypertrophies and becomes painful and villous, and Heberden's nodes, bony swelling at the knuckles,ipping of the femur and tibia at the knee-joint, and bony changes in the vertebrae may occur from irritation.

This stage has lately been described as a separate clinical entity under such names as climacteric, menopausal, hypoglandular, and endocrine arthritis, and has been attributed to a failure of the thyroid, pituitary, and ovarian secretions exercising a direct effect on the joints. I take this, however, to be an erroneous interpretation of what happens. In all these cases a history can be obtained of rheumatic pains for years past—often very many years—and dating from acute rheumatism in childhood, or from influenza or some other infection. Whenever such a person lays on fat, as so frequently occurs at the menopause, the rheumatic symptoms become greatly intensified, and the increased weight throws a certain strain on the joints, and especially on the knees. At this stage many of these patients have no arthritis, but in time some of the synovial membranes and bones (through their periosteum) become

involved in the general fibrositic changes. In men affected with panniculitis the same clinical picture can often be seen, especially if they are stout and heavy. None of these people show any signs of true myxoedema or thyroid deficiency, and the condition is often met with long before the menopause, when menstruation is regular and when there is presumably no ovarian deficiency. If of child-bearing age these women bear children normally.

With regard to treatment, the principles affecting acute exacerbations and the original underlying causes have already been discussed, leaving for consideration how we may best get rid of the fibro-fatty overgrowth. In patients with a large amount of subcutaneous fat the most satisfactory results are obtained by means of diet and massage. The quantity of their carbohydrate food should be reduced by one-half or three-quarters, exercise suitable to the age and condition of each patient should be taken freely, and special medical exercises may be given in addition, and a daily dose of thyroid gland. The last has no specific action on the fibrosis, but assists in reducing weight. This regime should be continued until the patient has reached something like normal weight for the height and age, which often means a reduction of several stones. With loss of fat the symptoms lessen and the massage can be applied much more effectively, as the fibrotic tissue is then more directly reached. Patients of normal stoutness—and there are very many such—do not, of course, require these reducing measures.

The method of applying the massage is a matter of the first importance for successful treatment. It should be directed to the panniculus adiposus, and either powder or a minimum only of lubricant should be used. With the bare hand the grip is too firm and painful, and with much oil too slippery. The manipulation is a little difficult to describe, but very easy to demonstrate. A mass of the panniculus adiposus should be grasped with one or both hands, holding it between the thumb and thenar eminence on the one side and the rest of the hand on the other side, and then the two parts of the hand approximated with adequate pressure and a slow movement. The skin is usually bound down to the subjacent tissues, and it too should be grasped and manipulated with the object of loosening it and making it more flexible. Such treatment is painful, often exceedingly so if not carried out gently, and bruising is very readily produced at first. It may take five or six weeks before any but very light pressure can be borne, but gradually the neuritis is reduced, and then harder treatment can be given. It is always, however, a painful and disagreeable and tedious process. The patient should always be warned that treatment must be continued for six or twelve months or even more, and that during that time several courses of massage of eight weeks or so will be necessary; and that if left untreated the condition is certain to go on from bad to worse. Many patients can be taught to treat themselves to a certain extent.

In cases where the fibrositis is of the hard brawny type dieting often fails to reduce the bulk to a satisfactory degree, the new tissue is much more resistant to massaging, and the prognosis is in consequence not nearly so good, but the symptoms can always be greatly ameliorated. Such patients usually remain "rheumatic" and require renewed courses of treatment from time to time for relief of their symptoms.

Finally, as regards the important question of individual prophylaxis, I have formed the opinion that many sufferers from muscular rheumatism and panniculitis have acquired the fibrositis at an early age from an attack of acute rheumatism, and continue to harbour in a latent condition the specific germ of the disease. After recovering from the acute attack children should be carefully examined and any fibrositic areas massaged while the deposits are still soft and easily dispersed. Further, they should be given at bedtime for some months a nightly dose of sodium salicylate or salicin, with the object of eradicating the infection. After tonsillitis, influenza, and other acute infective causes, all patients should be similarly examined, and, if necessary, treated by massage. Unfortunately we have no specific drugs to help us for most of these cases.

## Hunterian Lecture ON NEW METHODS OF SURGICAL ACCESS TO THE BRAIN.

BY  
H. S. SOUTTAR, C.B.E., D.M., M.Ch., F.R.C.S.,  
SURGEON, LONDON HOSPITAL.  
(With Coloured Plate.)

THE problem of obtaining easy access to the interior of the skull has become of increasing importance with the modern demand for large openings, in which it shall be possible to replace the bone without fear of risking its vitality. The problem raises several questions, each of which demands separate consideration. First we must consider how access to the skull itself is to be obtained; secondly, our osteoplastic flaps must be so designed as to secure their blood supply; thirdly, the actual division of the bone presents a mechanical problem of no mean order; and lastly, the control of hæmorrhage at every stage of the operation is of vital importance to the patient.

### *Blood Supply of Scalp and Skull Independent.*

It is a primary condition in the formation of an osteoplastic flap that a sufficient blood supply for the bone should be maintained, and with this object it has been customary to turn down the scalp with the bone in one piece. I believe that this is quite unnecessary, and that osteoplastic flaps can be formed with equal security and with far greater facility if the scalp is turned down first. The skull receives the great bulk of its blood supply through the muscles which are attached to it and from the mucous membrane which lines its cavities. The dura forms a periosteal lining, and as such carries its own blood supply, but only minute vessels from this source actually enter the bone. The scalp, on the other hand, is separated from the periosteum of the calvaria by a layer of loose areolar tissue, in which there can be found only a few vessels of trivial importance, which can have no appreciable effect on the vitality of the skull itself. These points will become clearer if we consider certain details in the anatomy of the scalp and the calvaria.

### *Structure and Blood Supply of Scalp.*

The scalp consists of three layers—the skin, the superficial fascia, and the galea aponeurotica. The skin is very thick, the galea tough and thin, and they are bound together by a thick and dense layer of superficial fascia, in which ramify the whole of the blood vessels and nerves. So closely, indeed, are the three layers connected that the scalp must be regarded as a single structure, carrying a blood supply which is for all practical purposes entirely

FIG. 1.—Muscles and blood supply of scalp.

independent. The galea is a tough membrane stretched over the calvaria and really forming the tendon of the occipito-frontalis muscle. Posteriorly it is attached to the superior curved line of the occipital bone; anteriorly it joins the frontalis muscle, and through it becomes continuous with the orbicularis oculi, having no direct attachment to the front of the skull. Laterally it has a weak attachment to the temporal line and to the dense temporal fascia which covers the temporal muscle, but it can be readily separated from this fascia almost down to the level of the zygomatic arch. In the whole of its extent it is separated from the pericranium by a loose

areolar tissue in which a few small veins may be found, but which contains no vessels of practical importance.

The blood supply of the scalp arises from various sources, and all its vessels enter it beyond the limits of the attachments which we have described. In front the supraorbital and frontal arteries are derived from the ophthalmic branch of the internal carotid, and ramify upwards in the forehead. Laterally the superficial temporal branch of the external carotid extends upwards just in front of the ear, dividing at about the level of the upper margin of the lobe into anterior and posterior branches, which ramify widely over the whole of the side of the head. Posteriorly the occipital and posterior auricular arteries, both derived from the external carotid, supply the whole of the back of the scalp. Between these arteries there is the freest possible anastomosis, so that portions of the scalp can be raised in almost any direction without danger to their vitality. The point, however, which I wish to stress is that these flaps can be raised without endangering the vitality of the subjacent bone, since it is in no way dependent upon the scalp for its blood supply.

#### Blood Supply of Skull.

This will become still more obvious if we consider the blood supply of the skull itself. More than half of its lateral aspect is covered by the temporal muscle and its

FIG. 2.—Muscles and blood supply of skull.

fascia, whilst, behind, the broad surface of the occipital bone below the superior curved line furnishes an origin for the large mass of muscle which occupies the nuchal region. These muscular attachments can be made to furnish ideal hinges for osteoplastic flaps in almost any situation, they carry a blood supply sufficient to maintain the vitality of the bone, and they form, in our opinion, the only means by which the blood supply can be maintained. Their blood vessels are entirely distinct from those which supply the scalp. In the temporal region the chief vessels are the temporal branches of the internal maxillary artery, whilst in the occipital region the most important vessels arise from the occipital artery as it lies deeply beneath the sterno-mastoid and the digastric, actually grooving the occipital bone.

#### Scalp Flaps in Different Regions.

There are three primary regions from which the brain can be approached—the *temporal*, *occipital*, and *frontal*—and in each instance the scalp flap required presents certain peculiarities to which we must now direct attention. In each instance, however, the scalp flap should be so fashioned, if possible, as to overlap by fully half an inch the proposed incision in the skull.

FIG. 3.—Temporal scalp flap.

In the *temporal region* a flap of any dimensions may be formed, care being taken that the anterior portion of the incision lies well in front of the ear, so as to avoid injury to the superficial temporal artery. In this instance a great advantage is gained by first marking out the pedicle with two small incisions, one in front of and one behind the ear, tunnelling through with a blunt dissector in the areolar

layer, passing one blade of a soft intestinal clamp through the tunnel so formed, and with it clamping the base of the pedicle. If this is done there will be no bleeding whatever from the cut margin of the flap itself, and the attention of the surgeon can thus be directed solely to preventing bleeding from the opposite side of his incision. After the incision has been made and the bleeding arrested, the whole flap can be turned down as far as the clamp at its root without the division of anything except soft areolar tissue, and without bleeding from a single point.

In the *occipital region* the scalp can only be turned down as far as the superior curved line of the occipital bone, since below this point it is firmly attached to the muscles. If an attempt is made to raise it beyond this point the origin of the occipitalis muscle must first be divided and the skin must then be dissected away from the muscles to which it is united by dense and vascular fibrous tissue, and bleeding may be considerable. With the methods of approach which we now adopt we always respect this attachment, and never go beyond it. None the less we can turn down osteoplastic flaps in this region and even remove the bone without ever detaching the scalp from the muscles to which it so firmly adheres.

In the *frontal region* superb access to the bone may be obtained by very simple means. If an incision is carried boldly across the brow, coming down just in front of

FIG. 4.—Frontal scalp flap.

the ear, it will be found that the whole of the forehead can be turned down without the slightest difficulty, even beyond the upper margins of the orbit. It is true that the anterior branch of the superficial temporal artery is divided, but the forehead has an ample blood supply apart from this. I would again point out that even in this region the vitality of the bone is in no way jeopardized, and that an osteoplastic flap consisting of one-half of the frontal bone may be formed with perfect success on the temporal muscle as a base. When the scalp flap is replaced the suture line is entirely out of sight and the nerve supply of the forehead is still intact. I have repeatedly carried out all these procedures under local anaesthesia with a conscious patient; there has been an entire absence of either shock or pain; and in the case of the frontal flap the only additional precaution taken was to cover the patient's eyes and face with a sterile bandage.

#### Control of Haemorrhage.

The control of haemorrhage from the scalp is a matter of the very first importance to which sufficient attention is rarely paid. Any loss of blood at this point is entirely unjustifiable and may prejudice the further stages of the operation very seriously. Bleeding from the smaller vessels is best controlled by preliminary injection of the whole line of incision with 1/2 per cent. novocain, to which about 1 per cent. of 1 in 1,000 adrenalin has been added. At the same time it is our custom to infiltrate the whole of the subaponeurotic space in the operation area with the same solution. If this is done half an hour before the operation there will be no bleeding at all from the smaller vessels, and only the larger arteries will require attention. These may be seized in special forceps, such as those of De Martel, which grasp the whole thickness of the scalp, or they may be compressed by seizing the galea in artery forceps and drawing it over the cut area. The arteries themselves it is impossible to seize owing to the density of the tissue in which they lie. Personally I use small steel clips which are crushed with forceps on to the margin of the scalp. They hold it quite firmly without injury, they are so small that they are not in the way, and at the end of the operation they are very easily

I.—RIGHT FRONTAL OSTEOPLASTIC FLAP.

S. A. SENEH

II.—OCCIPITAL OSTEOPLASTIC FLAP.

S. A. SENEH

removed. In the case of the temporal flap I have already described the means by which bleeding from its margins is prevented. In the frontal flap the incision lies in a watershed area where vessels are very small, and the only two vessels which bleed are the anterior branches of the superficial temporal artery. The absolute bloodlessness of this line of incision is remarkable and a very great advantage.

Though a detailed consideration of the formation of osteoplastic flaps will be deferred until later, it will be convenient to consider the principles on which they are designed. In the temporal region a flap of any dimensions can be turned down on the temporal muscle. In the frontal region a large flap can be turned outwards, based as a hinge on the thick anterior portion of the same muscle. It is upon this muscle, and not upon the scalp, that the bone is in any event dependent for its blood supply. In the occipital region the whole of the back of the skull, as we shall see later, can be turned down on the nuchal muscles as a hinge, offering superb access to the whole of the posterior aspect of the brain.

#### The Division of the Bone.

We must now turn to the technical methods at our disposal for the division of the bone. In general terms three methods are in common use. In the first a series of trephine holes is made through the skull along the intended line of section, and these are joined by means of a saw or some variety of cutting forceps; in the second a Gigli saw is substituted for the forceps; for the third method a powerful electric motor is necessary, and the procedure consists in drilling a series of holes and joining these up either by means of a circular saw or some form of burr electrically driven. The first two methods are certainly primitive, and they demand a degree of exertion on the part of the surgeon which is detrimental to his manual skill when he comes to deal with the brain itself. The third method is effective, but it involves the use of a powerful electric motor and of a somewhat cumbersome and costly apparatus.

It has long seemed to me that it should be possible to cut through the skull entirely by hand if the problem could only be reduced to the terms of ordinary engineering. I have now succeeded in devising an appliance by which the skull can be divided entirely by hand with great facility and so smoothly that the operation can be easily accomplished on the conscious patient under a local anaesthetic. The appliance was specially designed for the formation of large osteoplastic flaps, and it enables the surgeon to form these with a facility, a rapidity, and a precision hitherto unapproached.

The instrument (Fig. 5) consists essentially of a stud, A, and a lever, C. By means of a locking device the stud is securely fixed in a half-inch hole previously drilled at the centre of the proposed bone flap. Around this can turn

FIG. 5.

the long lever C, on which slides an adjustable carriage, E, carrying a cutting chisel, F, which closely resembles the parting tool used in turning. This chisel can be advanced from a socket, H, which supports it, by means of a screw, G, so that the depth of the cut can be adjusted with the nicest accuracy. The method of procedure is as follows:

A very large flap consisting of scalp only is turned down. It must be so large as to overlap by fully half an inch the farthest limits of the bone flap which is to be formed. As there is no anastomosis whatever between the vessels of the scalp and of the bone, the turning down of the scalp does not interfere in the slightest degree with the vitality of the bone, whilst it greatly facilitates access to the latter. At the centre of the projected bone flap the muscle and pericranium are divided and drawn aside, and a hole is drilled

with a special brace. Into this hole is inserted the split stud, A, resembling an expanding mandrel, and into the centre of this is screwed a pin, B, which forces it open and locks it into place. The lever C is now dropped over the pin, and held in place by a nut, D, the carriage E is adjusted to the correct radius, and the cutting tool F is advanced

FIG. 6.

FIG. 7.

until it just projects from its housing, H. It will now be found that on swinging the lever round its fixed fulcrum the skull can be cut with astonishing facility, and without the slightest suspicion of violence. The cuts are taken in long sweeps, omitting the base of the flap, which is always so arranged that the skull at this point is thin. After each cut the tool is advanced a fraction of a millimetre and another cut is taken. In a very short space of time it will be found that the thinner parts of the skull have been penetrated and the cutting is now limited to the thicker part, where hard bone can still be felt with a seeker at the bottom of the slot. The form of the tool precludes any possibility of injuring the dura, but as soon as the seeker shows that the dura has been reached these parts of the incision will naturally be left alone. The bone is by this means almost completely divided over three-quarters of a circle, and two flat steel levers are now inserted into the slot which has been formed. Very slight pressure on these levers is required to crack the thin layer of inner table still remaining and the thin base of the bony flap, which is now turned down still attached to the soft parts, usually formed by the temporal muscle. The tool is set at such an angle that the margin of the bone flap

FIG. 8.

is bevelled, and therefore when the latter is replaced it lies snugly in position against the corresponding bevel of the skull itself. I know of no other method by means of which such accurate and firm coaptation can be obtained.

A difficulty in using the instrument arose from the impossibility of holding the head steady against such powerful leverage. This has been overcome by a simple device. After drilling the hole for the centre pin, another small hole is drilled at a distance of one inch from its centre. To enable this to be done accurately a jig is provided consisting of a stud, which fits the centre pinhole and from which a plate extends carrying a hole through which the drill is passed for the formation of the secondary hole. A long lever is provided with a pin, which fits the secondary hole, and with a hole through which is passed the centre pin of the instrument. The lever is thus rigidly attached to the skull, and if its extremity is held by an assistant it absolutely prevents rotation.

There is no instrumental limit to the size of the bone flap which can be formed, and a bony disc six inches in diameter can quite easily be turned down in the temporal region. For most operative work, however, a flap of from three to four inches in diameter will be sufficient. One of the most remarkable features of the instrument is the rapidity with which these large flaps may be formed, the average time taken for cutting the bone varying in my own experience between two and three minutes. The tendency of modern cerebral surgery is to explore the brain through very large openings, and it is for this purpose that the instrument has been devised. It is equally applicable to

any region of the skull, but it will find its greatest utility in the formation of large temporal flaps. The manipulation of the instrument is very easy, but its action is so unusual that it is absolutely essential that, before attempting to use it on the living subject, the surgeon should familiarize himself with its use both on the dried skull and on the cadaver.

#### *The Surgical Motor.*

Although the craniotome is so effective there are a few cases to which it is not applicable—where, for example, a flap of other than circular outline is required, or where it is necessary to enlarge an opening already made. For this purpose I have devised a new form of surgical motor which seems to present many advantages. (Fig. 9.) Its general arrangement will be understood from the accompanying illustrations, the simple construction being rendered possible by an entirely new form of universal joint. The entire weight of the operating end is supported by that of the motor, M, which acts as a counterpoise, so that the surgeon has the advantage of a powerful and massive tool, without the inconvenience of its weight.

FIG. 9.

FIG. 10.

Into the nose, N, of the instrument may be inserted drills, burs, or circular saws, and as these are driven slowly and with great power, their action is both safe and rapid.

The saws are provided with guard discs, so that they can be adjusted to cut to any depth from 1 to 10 millimetres. Starting with a large disc and a shallow cut, the size of the disc is gradually reduced and the depth of the cut correspondingly increased until the inner table is all but severed. A series of holes has already been drilled, and as these are joined up by the saw cuts the depth of the skull between each pair of holes can be accurately gauged. In this way the densest bone can be cut with the greatest ease and with absolute safety. As regards asepsis, the two terminal arms of the appliance can be boiled, after which they are encased, for convenience in handling, in a sleeve of stockinette.

#### *Osteoplastic Flaps.*

Having shown the possibility of obtaining a full exposure of the bone by first removing the scalp, and having described the apparatus at our disposal for dividing the bone, we are now in a position to discuss the actual formation of osteoplastic flaps. We shall consider these separately as they are required for approaching the lateral, posterior, or anterior regions of the skull.

#### *The Temporal Flap.*

Lateral approach by means of a temporal flap is the commonest mode of access to the brain. Not only is it required for the removal of tumours in the sensorimotor region and in the temporal lobe, but it is often the most convenient and effective method of obtaining decompression. A large scalp flap is first turned down, as we have already described, bleeding from the flap being controlled by a clamp across its base, and from the scalp by clips attached to its margin. The total loss of blood should be trivial, and all bleeding must be absolutely checked before the next step is taken. The scalp flap and the exposed area are carefully protected by gauze pads moist with warm saline.

The bone flap required is now marked out with a compass, and the bone is divided round three-quarters of a circle with the craniotome, the temporal muscle which is to form the hinge being carefully preserved. The levers

are inserted and the thin bone in the temporal fossa is cracked, when the bone flap can be turned down and out of the way. The bone usually cracks at a point half an inch or more from the base of the skull, and it is convenient to strip down the temporal muscle as far as the temporal crest and to remove the thin bone with punch forceps. In this way maximum use is made of the opening

FIG. 11.—Temporal osteoplastic flap.

in the skull, and if the bone is replaced the defect left at its base forms a very useful subtemporal decompression.

Although the opening made for exploration can scarcely be too large, it may happen that in the case of an inoperable tumour the opening made for exploration is larger than need be left for decompression. When it is suspected that this may be the case the following plan has been adopted with complete success. After centring the craniotome a preliminary cut is made half an inch within the outline of the proposed flap, the outer table only of the bone being cut through. The carriage is now readjusted to the full size of the flap, which is then formed as described. If, after exploration, it is desired to leave a permanent decompression the outer half-inch of the bone flap is easily removed with bone forceps. The bone now floats as a valve, surrounded by a half-inch gap, across which union cannot occur, whilst the temporal muscle which forms its pedicle furnishes an entirely adequate blood supply. In a case of vascular tumour on which we operated four years ago, in a boy of 12, this arrangement has answered perfectly, and the valvular action is still free.

#### *The Occipital Flap.*

Posterior approach to the brain has usually been obtained by piecemeal removal of the occipital bone below the lateral sinuses, and this has been generally regarded as a region entirely unsuited to the formation of osteoplastic flaps. The situation has, however, been entirely altered by the craniotome, which enables huge osteoplastic flaps to be turned down in this region with precision and safety, affording an access to the cerebellum, the brain stem, and the occipital lobes never before achieved. At the same time the bone, in whole or in part, can be replaced with perfect accuracy and with absolute security. The effectiveness of the method can be sufficiently judged from the fact that the whole of the back of the skull, from the lambda to the foramen magnum, can be turned down in five minutes with the utmost ease, without the slightest violence, and often without any change either in the pulse rate or the blood pressure of the patient.

A scalp flap is first turned down, as we have already described, as far as the superior curved line of the occipital bone, to which it is attached. This flap should overlap the proposed skull flap by half an inch. A point is now selected about half an inch above the external occipital protuberance, and here a hole is drilled for the centre pin. The bone at this point is very thick, and it may not be necessary to drill completely through; indeed, it is an advantage not to do so, as a large emissary vein may be encountered. Should, however, bleeding occur, it is immediately stopped by the insertion of the centre pin, which is then secured in place. The skull is cut as usual, and as it is here often half an inch or more in thickness the power of the craniotome is fully demonstrated. A channel is cut which divides the thick bone completely and extends below the lateral sinus on each side. With a specially guarded chisel the extremities of this channel are extended towards the foramen magnum, when it will be found that on raising the bone the whole posterior margin of the foramen magnum is included in the fragment. Seizing the upper margin of the bone in forceps it is drawn forcibly

backwards, so as to avoid injury to the medulla, and it is then turned downwards over the nape of the neck, still attached, of course, to the whole of the nuchal muscles.

The only risk in this procedure is that of haemorrhage from the large emissary vein which communicates between the torcular Herophili and the vascular diploë of the occipital bone. In raising the bone this vein is torn, and the finger of an assistant must be immediately applied to stop haemorrhage. A small piece of muscle, cut ready for the purpose, is now applied and held in place by the finger for three minutes, when it will be found to adhere firmly and to have stopped the bleeding. Occasionally a similar but smaller vein may be torn from the superior longitudinal sinus, but it is easily dealt with in a similar manner. There would seem to be no risk whatever of injury to the sinuses themselves.

The field now obtained is very remarkable. In the centre lies the torcular, the lateral sinuses spreading outwards on each side, whilst above these the occipital lobes are exposed to an extent of perhaps two inches. Ideal access to the cerebellum is offered, and if necessary the posterior arch of the atlas can be removed. But most important of all is the relaxation of the tentorium, which results from the removal of its posterior support, so that it can now move upwards freely and release the pressure on the medulla. Provided there is no undue pressure in the upper chamber this may provide sufficient decompression without any opening of the dura, and we have had a case of midbrain tumour with secondary hydrocephalus in which this procedure alone was sufficient to secure permanent relief. In any case a combination of this with aspiration of the ventricles will give all the relief of tension that can be desired.

Two other points must be noted. The exposure of the occipital lobes renders puncture of the lateral ventricles easy, and the surgeon has at his disposal a simple means of reducing the cerebral pressure to any desired degree. In addition, the full exposure of the sinuses enables him to introduce fluid into the circulation at the end of the operation, often a consideration of the most vital importance. The walls of the sinuses are by no means fragile, and if a fine needle is used puncture does not involve the slightest risk of bleeding, for the opening seals itself at once.

On dividing the dura over the cerebellum it will be found that the mobility of the tentorium is of the greatest advantage, for by displacing it upwards the available space below may be greatly increased. A still further advantage may be gained by freeing the dura on each side for a short distance from the skull, though care must be taken not to injure the large mastoid emissary veins.

Mobilization of the tentorium; so far as I am aware, is an entirely new procedure, and it is only rendered possible by the occipital osteoplastic flap which has been described. Without the craniotome the formation of such a flap is scarcely a mechanical possibility, for it demands the clean cutting of the densest part of the skull over a very large circle. The trauma to the patient which would result from attempting to do this by any other method would be so serious as to prohibit its performance. Moreover, the flap must be turned down with great rapidity if serious haemorrhage is to be avoided from the large emissary vein to which we have referred. With the method here described the actual turning down of the bone flap is practically

instantaneous, and in no case has the bleeding remained uncontrolled for a longer period than two seconds. I am so impressed with the value of mobilization of the tentorium that I feel that this possibility alone justifies the invention of the craniotome.

If removal of the bone is desired it should be peeled off the muscles from below upwards, when it will be found that they separate from it without any bleeding at all. The contrast with the haemorrhage which occurs in the usual method of stripping the muscle off the bone is very remarkable. It will, however, be necessary to cut through the aponeurotic attachments to the superior curved line with a pair of scissors. If the bone is replaced the margin of the foramen magnum and a portion of the thin bone above it may with advantage be removed, as can be done with the greatest facility.

#### The Frontal Flap.

Anterior approach is rendered much easier by the frontal scalp flap which we have already described. This places the whole of the frontal region at our disposal, and allows the formation of osteoplastic flaps on a generous scale. The thick anterior portion of the temporal muscle, the origin of which extends right up to the angular process of the frontal bone, furnishes an ideal hinge and preserves an adequate blood supply. If the craniotome is used the centre will usually be placed a little above the temporal line, and the line of division of the bone will be just above the superciliary arch and to one side of the middle line, although the latter may be crossed without risk if a really full exposure is desired.

This method of approach furnishes admirable access to the frontal lobe and, if this is displaced, to the falx cerebri, in its anterior portion. It is, however, of still greater value in the approach which it offers to the pituitary gland. If the bone flap is properly formed it will be found that the

whole of the bone overlying the frontal lobe has been removed, and that the lobe can therefore be displaced upwards with quite unusual facility. If the hyperextended position of the head is adopted it will be found that the frontal lobe actually falls away from the orbital plate, so that the route to the pituitary is opened up even without mechanical retraction, and all contusion of the brain is avoided.

In this region, if a very extensive exposure is required, or if there is uncertainty as to the side on which a tumour is situated, it is sometimes an advantage to form a large angular flap; or indeed to expose both sides of the brain at the same time. After the frontal scalp flap has been turned down this can be done with the greatest facility by means of the surgical motor which we have described and a guarded circular saw, after drilling a series of holes as guides to depth. One saw cut should be coronal, one horizontal and just above the superciliary arches, and one sagittal and to one side of the middle line. By this means a double exposure is easily obtained with very little disturbance.

The new methods of obtaining access to the brain which I have thus briefly described appear to offer considerable advantages over those in general use. They are exceedingly precise, they demand very little exertion from the surgeon, they involve a minimal destruction of the tissues,

## SMALL-POX AND CLIMATE IN ENGLAND AND WALES 1921-1927.

with November absolute humidities much below the average.

In a similar manner an early decline of the disease may be associated with unusually high absolute humidity in February, as in 1926, and the second slight rise in May and June of that year followed low absolute humidity in the former month, and the second sharp fall occurred as usual after the rise in the absolute humidity in June and July.

The foregoing data will suffice to demonstrate that the main features of the monthly small-pox curve year by year can be explained by the absolute humidity data to a remarkable extent in this country, as well as in India.

#### Rainfall and Direction of the Wind.

In a presidential address to the Royal Meteorological Society in 1890 Mr. Balwin Latham pointed out that small-pox broke out in this country after a very dry period in 1870 and in other such years. But Sir Arthur Newsholme found this relationship to be by no means constant, and he attributed the recurring epidemics, for want of a better term, to "epidemic constitution"—whatever that may mean. In India I showed a very close relationship between short monsoon rain and subsequent epidemic small-pox, and that in the only area with much winter rain in the North-west Frontier Province a slighter decline of the disease followed the cold weather rain, although the temperature is low there in the winter. This raises the question of the influence of rainfall on the disease in this country, so I have given the monthly data in inches at the bottom of my chart, together with the direction of the prevailing winds, which may next be studied.

In the first place, low rainfall in the winter and spring months of high small-pox prevalence is usually accompanied by low temperatures and north or east winds, and consequently low absolute humidity, favouring increased small-pox. We find examples of this in the remarkably low absolute humidity in June, 1923, associated with the sharp Gloucester outbreak; and in February and March, 1924, in relation to the late March and April rise to the maximum in that year, following an unusual decline in

February after the opposite conditions of south-west winds and relatively high absolute humidity in January. Again, the late April small-pox maximum in 1925 followed low rainfall, north-west winds, and very low absolute humidity of the previous month, and the very low rainfall of only 0.38 of an inch in December, 1926, accompanied by north-east winds, was followed by the highest small-pox rate of the whole chart in January, 1927, aided by continued low rainfall in that month. Once more, the rapid rise of the disease in November, 1927, followed low rains and north-east winds in October, and the further rise in January, 1928, followed low temperature and north-east winds, but with high rainfall in the last two weeks of December. Thus low temperature and absolute humidity, followed by increased prevalence of small-pox, are commonly associated in the winter and spring months with low rainfall and north or east winds.

When we turn to the summer period of low small-pox incidence we find totally different conditions, for at this season low rainfall is usually accompanied by high temperatures, which produce relatively high absolute humidities in this country in spite of low rainfall, and so are followed by decreasing small-pox—as, for example, in the second week in June, 1925, when in the absence of rain even a north-east wind was accompanied by very high temperature and absolute humidity, and was followed by declining disease. This explains Sir Arthur Newsholme's experience, for it is now evident that only scanty rains in the winter and spring months are likely to be associated with low absolute humidity and increasing small-pox, while low rainfall in the summer will favour high temperatures and low small-pox.

#### The Future Outlook of Small-pox in England.

The most striking feature of the chart is the steady increase in each of the last four seasons at an average rate of 160 per cent. over the previous year in geometrical progression, and there seems to be no apparent reason why this should not continue in view of the increasing neglect of vaccination in the rising generation. With the exception of the Gloucester outbreak in 1923 and the infection of South Wales last year, the great majority have occurred

in the North of England, no fewer than 615 of the highest monthly figure of 675 in January, 1926, having been reported from Durham and West Yorkshire. Possibly the lower winter temperature and absolute humidity in the North may be one factor in this distribution. The data are not yet sufficient to afford scope for forecasting the probable incidence some months ahead, as in India, but it may be significant that the less marked summer decline in 1924 than in 1923 and 1925 was associated with lower summer absolute humidity in 1924, as I should expect a cool summer to produce less reduction of the disease, and a cold winter and spring should favour an increase.

The immediate outlook is complicated by twenty-four counties reporting cases at the end of January, 1928, against nine at the same period in 1927, but against this is the fact that the great rise early in 1927 was largely due to small-pox getting out of control in Durham, with nearly half the total January cases in that one county, which is not the case this year. The recent very mild January and early February is unfavourable to the rapid increase of the disease, but in view of the maximum occurring as late as April in two years with especially low spring absolute humidity, it is too early to say whether the high small-pox rate of last year will be exceeded this year or not, but a cold spring is likely to result in some increase on the 1927 figures. A few more years of neglected vaccination and we are likely to possess better data for forecasting the epidemics here, as in India.

Nor should we forget that the present widespread mild small-pox is a reliable measure of what is likely to happen when the fatal African and Indian form once more gets a firm footing in the country of Jenner, as it nearly did in May, 1927, with five deaths among eleven cases in London, when a serious disaster was only stayed off by the fine teamwork of the medical profession in tracing and vaccinating contacts.

#### Conclusion.

The mild type of small-pox now endemic in England and Wales has increased each year for the past four seasons at an average rate of 160 per cent. on the previous year. Its seasonal prevalence is closely related to the absolute humidity, as I have previously shown to be the case in India. Low absolute humidity favours and high checks the disease, and in this country the mean temperature curve closely follows the absolute humidity one, although this is not the case in India, where the yearly epidemics can be foreseen several months ahead. In England the probable course can only be forecast at present for the succeeding month. A cold winter and spring are likely to result in increased small-pox.

## ERGOT POISONING AMONG RYE BREAD CONSUMERS.

BY

JAMES ROBERTSON, M.B., CH.B.,

AND

HUGH T. ASHBY, M.D., F.R.C.P.,

VISITING PHYSICIAN TO THE ROYAL MANCHESTER CHILDREN'S AND  
SALFORD ROYAL HOSPITALS.

ATTENTION was first drawn to the prevalence of symptoms suggesting poisoning by ergot by one of us (J.R.) some eighteen months ago. An increase in the number of cases showing symptoms has led us to investigate the condition thoroughly.

In the first place it was noticed that the disease is confined to the Jewish population of the city, and it is found that the symptoms are only met with in that portion of the Jewish community which uses rye bread as an article of diet. In no case is the condition met with among those who eat white bread.

We have carefully collected and recorded cases, and have had analytical and physiological tests made on the rye in order to prove the cause of the symptoms met with.

Early in the investigations it was observed that the general symptoms complained of were coldness in the extremities, numbness and lack of sensation in the fingers—a sensation like an insect creeping over the skin—headaches, depression, gastric disturbances, shooting pains, twitchings in the limbs, and staggering gait. It was further observed that the patients who complained of these symptoms were Jews and later that these Jews ate black or rye bread. On the other hand, none of the symptoms complained of were observed among that portion of the Jewish population who ate white bread. It was then suggested that the rye bread might be the source of the trouble. From this it was concluded that the symptoms were due to ergot, which, as is well known, so readily contaminates the rye. It was also noticed that the symptoms were much more pronounced in the Russian, Polish, and German-born Jews than in English-born Jews. This is explained by the fact that black bread is the bread commonly used on the Continent, whereas in this country its place is taken by white bread. Further, on account of its slightly bitter taste the black bread proves more palatable than the comparatively tasteless white bread. In addition to this, black bread is found to be more satisfying and is a little cheaper than white bread.

In some households it is found that one member may show no symptoms of ergotism whatever, whilst all the other members of the family are variously affected. Questions elicit the information that the unaffected member does not eat rye bread. In many of the cases first seen rye bread was stopped as an article of diet; this was followed by an early diminution in the symptoms, and a complete disappearance of them in most cases.

Rye is by far the most susceptible grain to infection by the parasitic fungus *Claviceps purpurea*. The grain is infected just as the flowers are opening, and the fungus enters at the end of the grain. The infection is only possible at this time, as the shell later becomes too hard for the fungus to penetrate. This most commonly occurs during a spell of sunshine following a cold, damp period, and the fungus can more readily be detected and demonstrated after a cold, damp raising and harvesting season—for example, that of autumn, 1927. Grain that is infected with ergot is seen to be black in colour, and when the cereal has been ground it can be observed as small black specks in the flour. It is probable that some consignments of rye grain are ergotized and some are free from the infection.

In the ordinary course of events precautions are taken to prevent infected grain from passing to the consumer. This is accomplished by a process known as "screening," whereby the grain is passed through a sieve and the large infected grains are eliminated. If a sufficient proportion of infection is demonstrated in this manner, then the rye so contaminated is classified as unfit for use. This method of detection, however, is inefficient, as it does not prevent the small infected grains from passing through. Thus all the small infected grains are passed on as fit for use. All the small infected grains are passed on as fit for use. All the small infected grains are passed on as fit for use. It is infected rye grain eventually becomes black in colour. It is therefore easy to identify with the naked eye. The grain is then ground and, after passing through the hands of various middlemen, is bought by the baker for bread-making.

Rye flour has very poor keeping qualities, and therefore, as far as possible, it is only ground to meet consumption. Old rye is the best for use; freshly ground rye deteriorates in twelve hours, when it gives off a peculiar fishy odour. When this is smelt the baker invariably takes it as an indication that the flour must be used up quickly; otherwise it will be unfit for use. The rye used is home-grown when available, although lately a large percentage has been imported from Canada. In the baking warm water is added to the rye, and it is then allowed to "sour"; this takes about twelve hours. The last batch may be eighteen hours old before baking. The bakers get twice the wage of ordinary bakers, and no machinery is used in the process.

Samples of the grain, rye flour, rye meal, and the bread were submitted to Mr. H. Heap, the Manchester city analyst, who reported that the grain submitted showed 1 per cent. of ergotized rye.

On cutting sections of the infected grain the fungus

*Claviceps purpurea* was at once seen invading it, and the fungus showed up well after staining with methylene blue and eosin. Sections of grain were also stained with iodine and potassium iodide for starch, none of which was seen in many sections, owing to its having been replaced by the fungus. Extracts from the rye were also tested physiologically for ergot, and the results were positive. Mr. Heap has, moreover, been able to grow the fungus from the rye.

The three chief constituents of ergot are spheacelinic acid, cornutine, and ergotine. However, ergot is not as yet definitely split up into its component parts or active constituents, and little is at present known of them specifically.

It is found that the average Jewish person consumes about 1/2 lb. of rye bread per diem, the flour of which contains 1 per cent. of ergot. Now 1/2 lb. of bread will contain about 5 to 6 oz. of flour, the rest being the water, which is added before baking; 5 oz. of flour equals 2,285 grains, of which 1 per cent. is ergotized. Each person is thus consuming 22.85 grains of ergot daily. The ordinary medicinal dose of ergot, taking the liquid extract of ergot as a sample dose, is 10 to 30 minims, which equals 10 to 30 grains. Thus each individual is taking rather more than the average dose of ergot each day. On account of freshness the ergot is also likely to be more potent than the medicinal ergot which has been kept for a time; also grain harvested during last autumn, if infected by ergot, is likely to contain fresher principles than that of the ergot from the previous harvest. It is found that rye bread takes time to rise before baking, especially in the winter months, when it is colder; and the flour mixed with water is allowed to stand for a time to "sour," during which time it is likely that the fungus may increase in quantity.

The symptoms observed in these Jewish patients correspond very closely with those produced by chronic ergot poisoning. The severity of the symptoms produced seems to increase with age, children being slightly and elderly people more acutely affected. This may be due to the elderly people having taken rye bread for many years. The foreign-born Jews, who have always eaten rye bread, are the most affected.

The first symptoms observed are coldness of the extremities combined with numbness. These symptoms are especially observed in tailors, buttonholers, etc., who find that their fingers are numb, and they have difficulty in keeping up with their work. They often notice that they prick their fingers without feeling it. Raynaud's disease amongst the Jews during this winter would appear to be more prevalent than heretofore. We have also come across a man, aged 47, who has a definite dry gangrene of both hands. The gangrene of this man is not associated with diabetes or any similar condition, and it is possible that, as a rye bread consumer, his gangrene is due to ergot poisoning.

A very typical sensation, which is found in all marked cases, is that of an insect creeping under or over the skin. This sensation is volunteered by the patients in most cases. Itching is also a common symptom. They also suffer from nervousness and depression, whilst headaches are well marked. Pains in the abdomen are frequently complained of, whilst among the more severe cases staggering gait and ataxia may be found. In most of the long-standing cases the blood pressure is definitely raised—for example, a woman aged 44 had a systolic blood pressure of 174.

It has been observed that these cases quickly improve when rye bread as an article of diet is discontinued.

A large number of the symptoms are due to general contraction of the arteries all over the body, and it is probable that if the poisoning should become more severe such serious conditions as Raynaud's disease and gangrene will become more frequent. Ergot has the power of contracting the pregnant uterus, and it is likely that chronic ergot poisoning may cause many abortions in early pregnancy. Unfortunately no record is available of these cases, as the Notification of Births Act only applies to children born after the expiration of the twenty-eighth week of pregnancy.

Treatment consists in stopping the consumption of the contaminated bread at once, and it is remarkable how quickly patients recover when this is done. They should be kept warm, and drug treatment is necessarily only palliative.

We are much indebted to Mr. H. Heap, M.Sc., F.I.C., the city analyst, for his careful analysis of the samples sent, and for his help and advice.

## THE INFLUENCE OF PARTURITION UPON INSANITY AND CRIME.

ABSTRACT OF A PAPER READ BEFORE THE MEDICO-LEGAL SOCIETY ON FEBRUARY 23RD, 1928.

BY

A. LOUISE MCILROY, M.D., D.Sc.,

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, UNIVERSITY OF LONDON (ROYAL FREE HOSPITAL).

IN 1922 the Infanticide Act relieved the courts from the painful task of finding a verdict of murder against a woman, mentally deranged by childbirth, who kills her newly born child.

The records of Broadmoor show that of the total female receptions from 1900 to 1924, 42.8 per cent. were in respect of child murders due to insanity associated with childbirth, the majority being crimes committed during lactation. To escape punishment a woman pleading puerperal insanity must prove (a) that she was suffering from the disease when she committed the offence; (b) that she was incapable of distinguishing right from wrong, or was under the influence of a delusion which prevented her from understanding at the moment the nature of the act which she was about to commit. The law assumes the delusion to be a fact, and if the fact would justify the act of violence then the prisoner would be entitled to a verdict of "guilty, but insane." This is provided for by the Criminal Lunatics Act, 1884. As many critics have pointed out, it is difficult to see how a person can be both insane and guilty. Before the Infanticide Act was passed the practice was for the jury to bring in a verdict of "not guilty, on the ground of insanity," which seems more logical. It should be borne in mind that a verdict of "guilty, but insane" can be passed upon a person sane at the time of the trial. A prisoner who is admittedly insane when about to be tried is, of course, unfit to plead, and is therefore detained during His Majesty's pleasure—that is, until he recovers his reason and becomes fit to plead.

From this it is plain that a woman suffering from puerperal insanity who murdered her child knowing that she was doing wrong would be liable to be convicted and sentenced to death for murder unless she were able to avail herself of the Infanticide Act, which makes an exception from the general law. On the other hand, if she established a defence of insanity she would be found guilty of murder, but insane, and locked up during His Majesty's pleasure, so that even in these circumstances she would suffer punishment of no light order.

The Infanticide Act provides (Section I):

"Where a woman by any wilful act or omission causes the death of her newly born child, but at the time of the act or omission has not fully recovered from the effects of giving birth to such child, and by reason thereof the balance of her mind is disturbed, she shall, notwithstanding that the circumstances were such that but for this Act the offence would have amounted to murder, be guilty of felony, to wit, infanticide, and may for such offence be dealt with and punished as if she had been guilty of the offence of manslaughter of such child."

As a corollary, Section II entitles a jury to find a verdict of infanticide where the charge is one of murder. To put the matter in a nutshell, in respect of a newly born child the mother has a period of absolution under the Act. When that period has expired she is dealt with on the same principles as other persons charged with murder. It is obvious that the Act requires two things—the woman must be mentally unbalanced and the child must be newly born. The absence from the Act of any definition of the term "newly born" has occasioned some discussion.

In a case relating to a young woman named Mary Donoghue, heard last November (1927), the Court of

Criminal Appeal, consisting of the Lord Chief Justice, Mr. Justice Avory, and Mr. Justice Salter, decided that a child more than a month old was not newly born within the Act. Subsequently, when correcting a statement in a textbook, Mr. Justice Avory expressed the opinion that a child three weeks old did not come within the Act. We therefore do not yet know what constitutes in law a "newly born child," except that one more than a month, and possibly three weeks, old does not come within the category.

In medicine the definition of a newborn child is somewhat vague. Obstetricians look upon the newly born or neo-natal infant as one under ten days, but frequently, for purposes of mortality statistics and diseases, this period is extended to one month. The convalescent period, or puerperium, of the mother normally lasts eight to ten days. At the end of this time the uterus has become reduced in size to a pelvic organ and the uterine discharge, or lochia, has ceased. The mother should therefore be normal, but convalescent. Ten days after parturition is usually the time agreed upon for the discharge of patients from hospitals, homes, etc. In private practice nurses are engaged for one month—witness the term "monthly nurse"—to look after mother and baby till the end of this period. In no case is the infant looked upon as newly born after one month from birth. A woman ought to be fully recovered at the end of a month from delivery. This might well be the legal standard under the Act in its present form.

The state of the law is most unsatisfactory so far as it affects cases of puerperal insanity, a term used to denote an abnormal mental state during pregnancy, labour, the puerperium, or lactation. The three chief forms are confusional, intermittent (manic-depressive), and dementia praecox. Latent tendencies are often stirred into action or precipitated by strain, exhaustion, or septic intoxication due to pregnancy, labour, or lactation. The attack may come on at any time within at least six weeks after childbirth, and may last for days, weeks, months, or even years. The nearer to labour and the more acute the attack, the more likely the patient is to recover quickly and completely. Usually the symptoms are those of the confusional type.

In cases of puerperal insanity it should be impossible to apply the ordinary rules relating to criminal acts by the insane. Apparently, as the law stands, a woman suffering from puerperal insanity who killed her child during the first day of its life, when presumably it would be regarded as newly born, would be guilty of the lesser offence of infanticide, whereas if she killed it when six weeks old she would be guilty of murder. Unless she could prove that she did not know that she was doing wrong, or was under the influence of a delusion, she might be sentenced to death.

It may be alleged that the Infanticide Act was intended to apply only to those cases in which a woman, after giving birth to a child, destroys it in a moment of mental anguish, although she knows she is doing wrong. If this reading of the Act is correct, it involves great injustice. Why should a woman who kills her child in such circumstances be treated with more leniency than one suffering from puerperal insanity who kills her child at, say, six weeks?

"Fear of exposure, shame, depression, even misery following the breaking of the moral law should not be confused with the symptoms arising from the disordered mind; such were the reactions of the normal mind—in fact were direct evidence of it."—J. R. Lord, *Journal of Mental Science*, July, 1927.

It may be said that the general law concerning acts by insane persons is a sufficient protection for sufferers from puerperal insanity, but this should not apply to puerperal insane cases.

Puerperal insanity is a well-recognized disease of motherhood, just as much as puerperal sepsis, and should be treated accordingly. A verdict of infanticide is equivalent to one of manslaughter, so that the offender does not escape lightly. If the prisoner relied upon the general law, and succeeded, the verdict would be one of "guilty, but insane," which would for all time brand her as a murderer and involve her imprisonment, perhaps for a long period.

The question is further complicated by the fact that puerperal insanity associated with crime most frequently occurs during the later periods of suckling, owing to physical and mental exhaustion. It occurs among badly nourished, overworked, and poorly fed women. It is due to the strain of nursing, and many milder cases are cured by weaning and general treatment. It is usually melancholic in type. The patient has suicidal or homicidal tendencies, often on impulse. She may cut her throat or strangle or drown her infant. Many patients are difficult to cure, and may end their days in an asylum. In many criminal asylums a considerable number of women are incarcerated because of homicidal acts towards their infants or children due to lactational insanity. This may be due to the fact that during lactation there is less skilled and constant supervision than during the puerperium. It must be recognized that as the acute maniacal non-homicidal type is most common within ten days of childbirth, and the later melancholic, suicidal, homicidal type during lactation, no legal distinction should be made between the various weeks or months when the symptoms occur. Needless to say, a woman afflicted in this way has "not fully recovered from the effect of giving birth" to her child, to use the language of the Infanticide Act. Therefore she should be entitled to the benefit of its provisions. If the law absolves the mother who commits infanticide upon her ten days old child, it should just as readily absolve the depressed mother who, worn out by lactation, puts an end to her infant's life.

The words "newly born" should be deleted from the Act, subject to a proviso that its operation should be limited to a period of six or nine months from the date of birth. It would afford protection for mothers suffering from what the medical profession recognizes as puerperal insanity, and it would also cover cases in which a woman, although not insane, in a moment of distraction kills her child shortly after its birth. It is important to mark the difference between the two classes of case. Unhappily the murder of infants is only too common, but they are usually killed either at birth or shortly afterwards. Therefore the extension of the period would in practice be limited to cases of puerperal insanity. It is fully recognized that many infants are deliberately made away with, and nothing should be done to weaken the law in such cases.

Motherhood is a necessity for the race. It is the factor of motherhood that makes the woman insane and causes her, when suffering from a disease due to motherhood, to destroy her offspring. There is a marked difference between a murder committed by a person suffering from general paralysis of the insane, or even paranoia, and one committed by a mother in the delirium of childbirth or exhausted by nursing.

A debate took place in the House of Lords on the Children Bill, 1908. Lord Loreburn, the Lord Chancellor, with the concurrence of the Home Secretary, proposed to insert a new clause providing that:

Where a woman is convicted of the murder of her infant, and that child was under the age of 1 year, the court may, in lieu of passing a sentence of death, sentence her to penal servitude for life or any less punishment.

In support of the clause he said that the passing of the death sentence in such cases was a mockery, as such a sentence had not been carried out since 1849. He thought that public opinion was shocked at the idea of the death sentence being passed in cases where it was manifestly inhuman to carry it out, and on the other hand it was very much to be regretted that the death penalty should be nominally inflicted when there was no reality behind it. The bill was ultimately rejected by 42 votes to 36.

Any change in the law should be limited to women who are mentally unbalanced owing to pregnancy, parturition, or lactation. The removal of the term "newly born" from the Infanticide Act, coupled with the proviso suggested in the present paper, would meet the difficulties recognized by speakers who opposed the clause.

The following points demand consideration: (1) The definition of the term "newly born" under the Act. (2) Should the law be altered to give more extended protection to the parturient and nursing mother who, when suffering from puerperal insanity, destroys her child?

## CHOLECYSTOGRAPHY BY THE ORAL METHOD WITHOUT THE USE OF CAPSULES.

WITH A REPORT ON FORTY CASES.

BY

HUGH MORRIS, M.D., D.M.R.E.,

RADIOLOGIST, SALFORD ROYAL HOSPITAL, MANCHESTER.

OWING to the objection which many surgeons still have to the use of tetraiodophenolphthalein intravenously, it is often necessary to administer the salt by the mouth. Much has been written on this subject, and various methods have been devised to allow capsules containing the salt to pass through the stomach with their outer coats intact. In this hospital, as in others, results were good with the aid of capsules which had been freshly coated with keratin, but after a short period of storage the capsules passed through the bowel undissolved. Realizing that this is a great disadvantage, especially in the smaller hospitals, or in private practice, where not many cases are examined, an attempt was made to dispense with the use of capsules altogether.

Spruill<sup>1</sup> examined a series of 23 cases, giving the salt mixed with cream of wheat, and this method was tried here in several cases. Whether the wrong patients were selected, or the wrong method of cooking the cream of wheat was employed, is not clear, but, at any rate, all the patients (five) on whom this method was tried developed sickness, and one had headache. An alternative vehicle was therefore sought for, and on the suggestion of Mr. Adamson, pharmacist to this hospital, the salt (grains  $v$  per 10 lb. body weight) was first mixed with white of egg before being added to the cooked cream of wheat (about 4 ounces). The idea underlying this was to fix, or partially fix, the salt until it should have passed through the pylorus, and, whether or not this effect was produced, the method has been satisfactory, as is shown by the following table and by the operative findings.

	Normal.	Pathological.
Number of cases where no unpleasant effects were produced	13	13
Number of cases where unpleasant effects were produced	7	2

The unpleasant effects produced were as follows: headache (1), nausea (5 cases, of which 3 were slight, and were due to the appearance of the mixture, which is certainly an objectionable feature of the method), diarrhoea (2 cases, one of which proved later to be a carcinoma of the caecum), and vomiting (one case, in which similar attacks had previously occurred, "but not so severe"); vomiting ceased after the administration of sodii bicarb. gr. xx, liq. morph. hydrochlor.  $m\bar{x}$ , aq. ad ss.).

It is no longer necessary to attempt to demonstrate the value of Graham's test, but the following figures show that this method of administering the salt is satisfactory. Of the "pathological" cases 12 have been operated on up to date, and 11 were definitely abnormal. The remaining case showed an apparently normal gall bladder; the report on this case was "doubtful pathological—gall bladder appears to throw a faint shadow." Three of the "normal" gall bladders were examined at operation, and were normal, at least to palpation and to the naked eye. In several cases the test was repeated, owing to the large amount of free salt which was present in the bowel, but in each of these cases the finding was the same at the second as at the first examination.

No attempt has been made to reproduce films of gall bladders; this has been done too often already, but the density of the gall-bladder shadow in this method was as intense as that obtained in any other oral method which has been employed here.

The cases examined were nearly all out-patients, and the address of the patient was noted on the first attendance at the x-ray department. Later, the following form, which

explains the technique employed, was sent, examination being arranged on a day to suit the convenience of the department, and the form being sent five or six days before the day of examination.

### SPECIAL X-RAY EXAMINATION.

#### Instructions to the Patient.

- (1) Take a dose of castor oil on.....night.
- (2) Attend at the dispensary of hospital on.....between 2.30 and 4 p.m. If desired a messenger may be sent—personal attendance is not necessary.
- (3) Take the material provided by the dispenser at 9.30 that night, as instructed.
- (4) Take nothing but water after this.
- (5) Attend at x-ray department at 9.30 a.m. on....., having taken nothing but water since taking the special meal.
- (6) Still having taken nothing but water, attend at the x-ray department again at 2.30 the same afternoon.
- (7) Have a meal, with as much fat in it as possible.
- (8) Attend for final x-ray examination at 4.30 p.m.
- (9) Report to the doctor who attends you in out-patient department on his next day for seeing patients.

The blank spaces are filled with the names of three consecutive days—for example, Monday, Tuesday, and Wednesday, if the examination is fixed for Wednesday.

I am indebted to the physicians and surgeons of Salford Royal Hospital for so kindly helping by providing cases, and for their useful suggestions at various times. I am also indebted to Drs. Rythell and Higgins for permission to publish these cases.

## THE OPERATION OF EVERSION OF THE SAC FOR HYDROCELE.

BY

RICHARD L. SPITTEL, F.R.C.S.,

SURGEON, GENERAL HOSPITAL, COLOMBO.

It has always been a puzzle to me why the simple and efficient operation of eversion of the sac for hydrocele is not practised more frequently in England. Of all operations for hydrocele it is perhaps the easiest, and achieves its object with least disturbance of tissue. It is, I think, much preferable to Bergmann's operation of excision of the sac, which, apart from the element of time involved, entails much stripping of tissue and tying of vessels, and is fairly frequently followed by post-operative haematomas; whereas eversion of the sac may easily be done within five minutes (I have often done it in two) and without tying a single vessel, the only buried suture being that holding together the edges of the everted sac.

One objection frequently urged against eversion is that it is apt to be followed by recurrence; but this need never be if the operation is correctly performed.

I do the operation under local anaesthesia as follows: An injection of morphine is given half an hour beforehand. The inguino-serotal fold is seized with the fingers of the left hand and the cord imprisoned; into the substance of the cord 5 c.cm. of a 1 per cent. novocain-adrenaline solution is injected. This renders the testicle insensitive to manipulation. The assistant now grasps the tumour with both hands, gathering up the loose serotum beneath, in such a way as to make it protuberant and tense. Along the line of the proposed serotal incision 10 to 20 c.cm. of a 1/2 per cent. novocain-adrenaline solution is injected. (I prefer the serotal to the inguinal incision, as there are few or no vessels to tie, and access is direct to the best part of the sac to incise.) An incision 2 to 3 inches long is now made over the tense tumour, and deepened layer by layer along the full length of the cut until the translucent sac becomes evident. Lane's forceps are clipped on to the edges of the serotal wound on each side. The point of the knife is plunged into an avascular part of the tunica and the fluid evacuated into a tray, but the blade is not removed from the rent until the cut edges are secured with forceps, otherwise their retraction makes them difficult to define. The assistant now releases his hold of the serotum and takes up one of the forceps on the tunica, the surgeon the other.

The opening is enlarged with scissors along the anterior surface of the sac, avoiding blood vessels. The testicle is drawn through the ample hole and the tunica everted like a cuff. The assistant holds up the testicle while the operator, introducing forceps or fingers into the scrotal wound, eases it out so as to form a roomy bed in which the testicle may lie when it is returned, without tension on the sac. Two pairs of Lane's forceps are now used on either side, one to embrace the cord (c), the other the gubernaculum (g), or rather what remains of it, which

FIG. 1.—Eversion of sac. T, testicle; E, epididymis; C, cord; G, gubernaculum remains; M, mattress suture.

is very little. The two forceps are held apart, displaying a web of tissue between them partly covered by the everted sac (Fig. 1). To this web the sac is secured by a through-and-through mattress stitch of catgut, or an opening is made in it with pointed forceps and the edges of the sac are approximated and secured through the rent with a single mattress suture. If the sac is very redundant an additional pleating stitch may be applied to it on the outer side of the cord, as is done in the usual operation. The testicle is now

replaced and the scrotal wound closed with an intradermal or a running mattress stitch, which, better than any other, obviates the tendency to incurvation of the edges. A scrotal suspender secures a gauze dressing in place.

The whole operation is very quickly performed. The points I would recommend as safeguards against recurrence are: (1) the making of a new bed for the testicle by easing out the depths of the scrotal wound; (2) the securing the edges of the sac to the web of tissue behind the testicle.

In the operation as it is usually done the everted sac is merely constricted by a stitch or two beside the cord, and no new cavity is made for the testicle. There is thus a tendency—though not as often as is supposed when the technique is careful—for the sac to retrovert when returned. Most recurrences, I feel sure, occur at the time of replacement, or very shortly afterwards, for “the endothelial surface of the serous sac faces the serotal fibrous and cellular tissues to which it becomes adherent in a short time” (Jacobson).

FIG. 2.—Jaboulay's operation.

Jaboulay in his original operation released the testicle by ligating and dividing the gubernaculum testis, and then folded the two sides of the divided sac behind the testicle and fixed them there with a few sutures (Fig. 2), one of which included the superficial tissues of the cord (Binnie); or he even cut away, in addition, part of the redundant sac before stitching them together behind the testicle (Thomson-Walker). No recurrence can follow such a procedure, but I think that in the usual class of ease it involves unnecessary interference with structure, though when the sac is thick and eversion difficult it is best to open it up, and then to peel off the parietal tunica from the thickened adventitious coverings, and thus, having released the testicle, to evert round it and the cord the now membranous tunica, as in the Jaboulay operation. In Wylls Andrews's “bottle” operation a small opening is made in the upper pole of the sac and the testicle is displaced through this and the sac inverted and drawn up the cord—a procedure which gives no absolute safeguard against recurrence.

Eversion of the sac is, generally speaking, contraindicated when the sac is very much thickened and calcified, for the main reason that it does not then reduce the size of the tumour to any extent; but in these cases, and even in the leathery sacs of infected haematocoeles (and incidentally in pyoceles), I have often saved testicles that might otherwise have been sacrificed by everting the sacs, swabbing out their roughened inner surfaces with zinc chloride

solution, packing them with iodoform gauze and leaving the wound partially open; and instituting in a day or two Carrel-Dakin drip until the cavity gradually obliterated itself. It is remarkable what a degree of pliancy and shrinkage the sac eventually attains.

## A METHOD OF MAKING A BLOOD FILM.

BY

FREDERICK COCK, M.R.C.S., L.R.C.P.,  
SURGEON COMMANDER, R.N.

THE following method of making blood films is one of several tried in an attempt to get a more even distribution of the red and white blood cells. In an ordinary blood smear most of the leucocytes are found at the margins of the film, but the method about to be described leaves the majority of these cells in the centre of the film. This may be a step in obtaining the result originally aimed at—namely, even distribution of cells in a film.

A piece of glass about the size of a half-plate negative (a in the accompanying diagram) is cleaned, and on one side white paper is gummed so that the quality of the film can be more readily observed in preparation; b and b are each two glass slides stuck together with Canada balsam and mounted two inches apart on a; c is a single glass slide mounted in the position shown.

A drop of blood is taken on the end of a slide and placed between b and b, and a second slide is made to rest on b and b at right angles to the first, so that

there is the thickness of a slide separating the glass surfaces between which the drop of blood lies. Contact of blood between upper and lower slides is made by raising the latter,

which is then allowed to fall back on the stage. The upper slide is now passed over the lower, the drop of blood following and leaving a very thin film behind, the time taken to traverse the slide being about thirty seconds. The margins of such a film consist mostly of red blood cells, while in the central zone numerous white blood cells and blood platelets are deposited. This arrangement is so striking that after using Leishman's stain the bluish tint of the central zone, due to the basophil elements of the blood, can be seen by the naked eye; the margins are stained pink. Under the microscope the numerous white blood cells and blood platelets in the central zone immediately arrest attention, and in some specimens there will be fields where not a single red blood cell is to be seen. The number of white blood cells in a given field varies considerably, but fifteen to thirty cells are quite commonly observed, and I have counted over sixty.

Differential counts are rapidly made, but since occasionally the white blood cells in a field are very numerous confusion is likely to arise at first in counting; after a little practice large numbers can be dealt with, or the difficulty may be met by using a higher magnification.

The results of such “drop smear” preparations compared with ordinary blood films may be enumerated as follows:

1. In drop smears most of the white blood cells are found in the centre of the film, while in ordinary films they gather at the margins.
2. There is a tendency for the various white cells to occur in groups—for example, numbers of polymorphonuclears are found together, and so with the other kinds of cells.
3. In comparing differential counts I find almost invariably an increase of about 8 or 10 per cent. polymorphonuclears and 4 per cent. eosinophils over the counts made with films prepared in the ordinary way. This is possibly explained in the next paragraph.
4. In an ordinary blood film basophil masses are sometimes observed. These I take to be detritus from ruptured cells,

and many more such masses must be carried to the end of the film in preparation. Ruptured eosinophil cells also are sometimes seen, and are very obvious, provided that the granules of the cells have not been scattered too far apart. It appears that the eosinophil is very easily ruptured, and the polymorphonuclear comes next in this respect. In a drop smear evidence of ruptured cells is seldom observed, and, considering that the film is made by passing a drop of blood over the slide, it is not likely that cells will suffer mechanical injury.

5. In drop smears the cells of the central zone are well separated one from another, they suffer little if any distortion, and they take the stain well. Red blood cells can be studied at the margins of the film, but it is in conditions where information regarding the white blood cells is required that the above method would appear most useful.

The question of the comparative accuracy of differential counts in the two methods is rather complicated. For instance, in comparing counts of 100 cells from a blood film made in the ordinary way it is not uncommon to find a difference of 10 per cent. in the polymorphonuclears, and the final result after counting 300 or 500 can only be an approximation. For the present I am not prepared to make any statement regarding the comparative accuracy of the two methods.

The following advantages of examination of pathological fluids by the drop smear method are worth noting: the films are thin and evenly spread; the results are far better than those obtained by using the end of a slide or the platinum loop; the cells suffer no damage; casts are often spread out in a beautiful fashion, and, owing to the thinness of the film, micro-organisms are readily recognized. There is no difficulty in making the films, and others may be able to devise further useful modifications of the method.

### MEDICAL, SURGICAL, OBSTETRICAL.

#### OEDEMA OF THE UPPER EYELIDS.

APPARENTLY trivial symptoms and signs may frequently be indications of serious disease, and, conversely, the opposite occasionally holds good—grave signs and symptoms resulting from comparatively simple conditions.

Oedema of the upper eyelids is a particularly instructive example of the latter, and requires especial wariness on the part of the practitioner.

A robust schoolboy is seen, presenting an alarming oedema of one or both upper eyelids and a raised temperature. The swollen area is so tender and so suggestive that an exploratory operation is undertaken for supposed acute frontal sinusitis, but no disease is discovered. Despite operation the oedema persists, until the actual cause of the condition becomes self-evident by the staining of the patient's dressings or pillow, which indicates a septic wound or abrasion on some part of the scalp, originally sustained some days previously and completely overlooked. Antiseptic fomentations produce rapid resolution of the oedema, which operation had failed to relieve.

I have seen two cases of this type, both in young schoolboys. One case followed the course just depicted, while the other rapidly resolved after less drastic treatment. Curiously, in both cases the wound was found in the occipital region of the scalp.

The swelling of the upper eyelid is no doubt due to the spread of infection along the lymphatic network in the subcutaneous tissue of the scalp, which is continuous with that in the loose areolar tissue of the lid. The condition, I believe, is well known to ophthalmic surgeons, but seems to deserve wider appreciation.

Liverpool.

JOHN ROBERTS, M.B., F.R.C.S.

#### FOREIGN BODY IN THE BLADDER.

ON observing a case reported under the above heading in a recent number of the JOURNAL (December 17th, 1927, p. 1140), I thought the following somewhat similar case might be worth recording.

An unmarried woman, aged 20, was admitted to hospital on November 8th, 1927, having been diagnosed as a case of ischio-rectal abscess (right-sided) by her own medical attendant. For about a fortnight previous to her admission she had had pain and tenderness in the right buttock. For about six months she had been treated for pyuria, which, in spite of clearing up on the exhibition of hexamine, always recurred when the hexamine was discontinued.

On admission she complained of intense pain on defecation and of pain in the right buttock. There was an indurated, red area about 1½ inches in diameter over and just external to the ischio-rectal fossa.

On November 11th she was given an anaesthetic and an incision was made into the inflamed area. About a cupful of purulent and necrotic material was evacuated, and then the seep which was being used impinged on something hard and slightly mobile. On digital examination this was felt to be a speicle of unknown material. A piece about 1 inch long was broken off and turned out to be lead pencil. Slight bleeding from the urethra led to investigation there, and on passing a finger into the bladder—an operation rendered simple by the fact that the urethra was dilated so as to admit a finger easily—it was found to be almost completely filled by a soft, crumbling mass of phosphatic material. This calculus was broken down, and embedded in it was found the remainder of the pencil, which had pierced the posterior wall of the bladder just to the right of the trigone. The pencil was removed, and, with the piece removed via the ischio-rectal fossa, measured 4½ inches in length. The bladder and sinus in the buttock were irrigated very thoroughly with boric lotion, and drainage of the sinus provided for. An uninterrupted recovery was made, the opening in the bladder healing up spontaneously, and the patient was discharged on January 1st, 1928. Micturition was normal, and the urine was normal also.

On being questioned the patient stated that two years previously she dreamt she was going to have a child, and inserted the pencil then with the object of preventing this.

It seems remarkable that the pencil, after penetrating the bladder, should reach the ischio-rectal fossa without doing any damage to the vagina or rectum, alongside both of which it lay.

I am indebted to Mr. C. J. Pinchiug, O.B.E., for permission to publish this case.

HARRY D. CHRISTIE, M.B., Ch.B.,  
Resident Medical Officer, Gravesend and North Kent  
Hospital.

#### THREE PERFORATIONS OF THE ILEUM CAUSED BY FISH-BONES.

THE following is an unusual case of general peritonitis resulting from perforations of the ileum due to swallowed fish-bones. The patient, being a staunch devotee to Christian Science, at first refused admission to hospital, then relented; she later refused operation, and finally consented only when in *extremis*.

During the night of April 6th-7th, 1927, an unmarried domestic servant, aged 49, was admitted to hospital with a history of sudden onset of severe abdominal pain, stabbing in character, on April 3rd, necessitating confinement to bed. There was some relief the next day, when she vomited two or three times. The bowels were quite normal. In the early morning of April 5th the pain was much worse, but this passed off, and she was able to perform her domestic duties. In the evening of this day a marked increase of the abdominal pain compelled her to return to bed. She vomited several times during the night, and was unable to retain food or fluids. In spite of all this she did not consult her doctor until the evening of April 6th, when he advised immediate removal to hospital. To this she objected, but when he repeated the advice three hours later she consented.

On admission the abdomen was somewhat distended, there was generalized rigidity, particularly in the lower abdomen, and a diagnosis of general peritonitis was made with no little assurance, but the cause remained obscure. Operation was advised but refused, and for four hours the patient remained adamant, consenting to operation about 3 a.m. on April 7th.

**Operation.**—The abdomen was opened through a paramedial incision. Free brownish, stinking sero-pus was found in the abdomen, the intestines being generally distended and inflamed; the appendix and pelvic viscera were normal. In the course of searching the pelvis for a cause of the peritonitis a sharp point was felt in the wall of the ileum; this proved to be the point of a fish-bone projecting from the wall of the gut, around which the intestinal contents had escaped. The bone was removed and the perforation sutured. The whole of the gut was then carefully examined and two other similar points were found; the bones were taken out and the wall was repaired. Pelvic drainage was instituted and the abdomen closed.

The patient's condition was extremely poor at the end of operation, but convalescence proceeded without hindrance to complete recovery.

Questioned as to the mode of introduction of these bones, the patient admitted having hurriedly taken a large meal of brill on the night of April 1st, and that she had had difficulty with the large coarse bones. These have been examined by Mr. Henry Crowther, curator of the Leeds City Museum, who states that the specimens are probably brill bones, and draws attention to certain characteristics—namely, the fluting, the elasticity, the hollowness, and finally, the very sharp point.

GEORGE ARMITAGE, M.B., Ch.M., F.R.C.S.

Leeds General Infirmary.

## SUPERNUMERARY THUMBS.

A CASE of bilateral polydactylism has recently come under my care, and may be of some general interest.

The patient is a woman, aged 25, under treatment for bronchitis. The deformity consists of supernumerary thumbs. The thumb of the right hand has two almost parallel proximal phalanges, and is nearly twice as thick as the normal from the head of the carpal to the interphalangeal joint, which is greatly enlarged; here the thumb is cloven into two perfectly formed terminals, inclining at an angle to each other in a forceps-like fashion. The left thumb had also a completely formed but rather small extra top, projecting at a right angle from the lateral aspect of the interphalangeal joint. As this had no communication with the joint cavity, and as it seemed to be a nuisance, I removed it, under local anaesthesia, by the simple expedient of transfixing it through its base, tying a double ligature and cutting away the redundant part. Both thumbs function to the full extent, and the left one has now a normal appearance. The closest inquiry into the family history reveals nothing abnormal on either side, and the woman is herself the mother of three normal children.

The evident lack of hereditary influence and the bilateral, and almost symmetrical, nature of the deformity make the case somewhat remarkable.

Leeds.

R. H. MITCHELL, M.B., B.Ch.Dub.

## Reports of Societies.

## VESICO-VAGINAL FISTULAE.

At a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, held in the Royal College of Physicians on February 3rd, the president, Dr. GIBSON FITZGIBBON, read a note on two cases of twisted broad ligament with cyst, and showed specimens. The interest in the specimens was that both showed necrosis from strangulation. Both patients had a period of symptoms pointing to an "acute abdomen," but these tended to subside, and the condition might have been overlooked in the first case, except that the patient complained of pelvic pressure, which it was thought might be due to prolapse. In the second case a history of an acute attack suggestive of acute abdomen two years before the present attack was obtained. The symptoms, however, subsided, and from the nature of the adhesions and the condition of the pedicle of the tumour it seemed likely that the attack was due to twisting of the pedicle, while the present attack was most probably due to some intermittent and partial intestinal obstruction caused by adhesions. The president then showed a third specimen of an ovarian cyst with a twisted pedicle. This patient was operated on soon after the torsion had occurred, and while the symptoms were still acute; she showed haemorrhage, infarction, and it was doubtful whether the symptoms would have subsided without operation.

Dr. L. L. CASSIDY read a paper on vesico-vaginal fistulae occurring during labour. He said that injuries to the urinary tract during labour might be due either to wounds caused by instrumental delivery or to trophic disturbances, the result of prolonged labour. The nature and extent of the injuries due to the latter cause depended upon the amount of pressure and the length of the labour, resulting in (1) ischuria puerperalis, with puerperal cystitis if infection follows; (2) pressure necrosis; (3) vesico-vaginal fistula, following necrosis. The last-named condition was more likely to arise in the case of flat pelvis than in a generally contracted one, where the pressure was more evenly distributed. He mentioned the suggestion put forward by Fritsch that the frequency with which vesico-vaginal fistulae occurred amongst Polish Jews was due to the early age at which they married, the immature pelvis causing such compression and over-stretching of the soft parts that fistulae followed. Where injuries to the bladder resulted from interference with delivery their more common causes were false indications for interference, deficient technique, or both combined. The lesion most commonly arose after forceps delivery, especially high forceps, and sometimes after perforation. Brow presentations, delivered as such, might also cause severe bladder injuries. Ureteric fistulae sometimes arose. According to Bum and Docderlein each advocated an operation for the closure of such fistulae, but the operation of lower uterine segment Caesarean section would probably take the place of the methods which necessitated splitting of the pelvic bones. Intraperitoneal lesions of the bladder should not arise during the course of gynaecological operations. During vaginal Caesarean section the bladder should be carefully kept out of the way by means of an anterior speculum during division of the cervix. Difficulty was sometimes encountered in the recognition of fistulae, both by the patient and by the obstetrician. Should such doubt arise careful measurement of the amount of urine passed in the twenty-four hours should be made, and catheterization or even cystoscopic examination carried out if doubt still exist.

In regard to treatment Dr. Cassidy held that the most important point was that no attempt should be made to repair the fistula until three months had elapsed since the birth of the child, on the grounds that safe union would not take place, and that spontaneous healing, though rare, might occur. This was favoured by a normal puerperium. Should there be signs of spontaneous healing a retention catheter should be used. Three important principles were to be borne in mind in connexion with the repair of vesico-vaginal fistulae: (1) Great care must be taken that no trauma of the bladder was occasioned during previous cystoscopic examination. (2) There must be thorough exposure of the parts and complete separation of the bladder wall from the vaginal mucous membrane, so that the edges might be brought together without tension and tied loosely. (3) A retention catheter should be left in for seven days. Dr. Cassidy concluded by bringing to the notice of the Section a series of ten cases which had been treated in the Coombe Hospital since 1922, and in which the above principles were observed. In nine of these cases the patients were completely cured; one was considerably improved and could retain urine for three hours, but there was still slight leakage. Nine of the women were delivered previously by forceps. One fistula followed upon amputation of the cervix.

The President remarked that in some of these cases there was considerable loss of tissue in the process of sloughing, and there was practically no cervix left. He thought that the question of closing vesico-vaginal fistulae really depended on the amount of cicatrization, and in being able to hold the bladder wall together. If this could be done the case usually healed up very well. Dr. Cassidy had referred to fistulae occurring following pubiotomy; he (the president) did not think that this often happened. While he was Master of the Rotunda he had seen only one instance; in no other case had he ever had any bother with bladder fistulae. After confinement a patient often suffered from loss of control for some time, but he thought it better to leave time—even as long as three months—for cicatrization to occur before operating. It was important not to operate in a hurry. Mobility of the bladder seemed to him the essential point in closing bladder fistulae.

Dr. D. G. MADILL suggested that with large fistulae it would be very difficult to get the amount of separation necessary in order to bring the bladder wall together. He had not had experience of large fistulae, but in some cases of small fistulae he had had difficulty in getting an absolute closure of the bladder; when the catheter was taken out there was a slight leakage, and the operation had to be performed over again before this cleared up. He had recently adopted Mayo's type of operation in three cases, and the fistulae all successfully closed straight away. He had experience of other operations, such as flap splitting, but in his opinion the essential part of the operation was separation of the bladder from the anterior vaginal wall for a considerable area all round.

Dr. J. S. QUINN said that he had been working with Dr. FitzGibbon at the Rotunda Hospital when they had had a series of cases of vesico-vaginal fistulae, and in three of the larger cases there had been no question of closing the fistulae altogether at the first operation. In one case they had seen what looked like a cystocele, but it turned out to be the fundus of the bladder which had prolapsed through the non-existing base of the bladder; in this case the bladder had sloughed away. Every case of vesico-vaginal fistula should be treated on its merits, and it was a mistake to suppose that because one operation was successful in a certain case it would be successful in every case. To his mind the main thing was to bring together the bladder walls with no pressure on them; if this could be achieved by any method, success would almost invariably follow. Recently these cases had become comparatively rare; older obstetricians had met with a great deal more of this kind of work; in fact practically all their work had been the closing of vesico-vaginal fistulae.

Professor A. H. DAVIDSON said that Dr. Cassidy's results were so good that they made it possible to approach the operation of closing of a fistula with a much greater degree of confidence. He had recently had two cases of fistulae which had been very difficult to diagnose: one was a case of uretero-vaginal fistula. He had made a supra-pubic incision and dissected down till he had come on the left ureter; he had then followed up to the bladder, and found it half opening into the vagina and half torn into the bladder. The fistula had been cured, and he had been able to catheterize the ureter later on. The second was a case of fistula following operation for prolapse. He had opened the abdomen and the fundus of the bladder had split right across, and he had got at the fistula from inside the bladder. The fistula had not closed, and he thought he would have to operate again. It was possible that the fistula would now be more accessible by the vaginal route.

### ETIOLOGY OF CHRONIC ARTHRITIS.

At a meeting of the Manchester Medical Society on February 1st, with the president, Dr. J. GRAY CLEGG, in the chair, a discussion on the etiology of chronic arthritis was opened by Dr. J. B. BURT.

Dr. Burt began by protesting against the theory that all chronic arthritis was caused by some focal sepsis: it was just as reasonable to say that there was only one cause of chronic arthritis as to assert that there was only one cause of heart disease. Certain authorities were quoted to show some of the fallacies of the focal sepsis theory. Trauma and vitamin deficiency were briefly mentioned as possible causes, and also gout and peptone hypersensitiveness. Subendocrine conditions were discussed at length as a further cause, and the distinctive clinical signs of arthritis due to endocrine deficiency were described. These occurred chiefly in women at the menopause, but were also seen in girls at the onset of puberty, in thyro-pituitary deficiency, and in some cases of osteo-arthritis of the hip in men over 60. Reasons were given why this type had not been recognized as a special group.

Mr. HARRY PLATT agreed that there was a tendency to exaggerate the importance of focal sepsis as a primary etiological factor in chronic arthritis as a whole, but the question was still unsettled. The bacteriological and histological examination of tissues removed in cases of osteo-arthritis of the hip had given conflicting results. Cultures made from osteophytes and from portions of the distorted head of the femur had proved sterile in the speaker's experience, in contrast with the findings of Warren Crowe. On the other hand, the histological changes in the thickened joint capsule resembled those seen in other forms of fibrous tissue lesion where a definite inflammatory or microbic basis was admitted. Mr. Platt then discussed certain types of chronic arthritis. A pure traumatic arthritis without the intervention of other etiological factors had long been recognized, and was seen to follow faulty union in fractures of the shafts of the leg bones; or fractures involving the ankle-joint itself. Another factor of great importance was static error or incongruity

of joint surfaces. Maladaptation of joint surfaces was by no means uncommon, particularly in the hip-joint. This condition obviously could follow an injury or a mild inflammatory attack. But more interesting still was the joint incongruity due to congenital causes. In recent years the significance of the minor congenital anomalies of the hip-joint had been much studied by Munk Jansen, Calot, and others. Congenital subluxation of the hip was present in a fair proportion of otherwise normal individuals. Such hip-joints tended to react to conditions of strain or infection known as pseudo-coxalgia. Calot had claimed that the affected subluxation, and that the osteo-arthritis of middle life represented superimposed changes in a hip already defective from birth. Mr. Platt thought that this sweeping dictum could not be accepted, but it was fair to state that the very beginning had been known to become the seat of chronic arthritis in later life.

### SURGICAL TREATMENT OF DIVERTICULITIS.

At a meeting of the Liverpool Medical Institution on February 2nd Mr. K. W. MONSARRAT read a paper on the surgical treatment of diverticulitis.

Mr. Monsarrat first described the distribution of diverticulitis, and of this development in the colon according to the figures given by Dr. Spriggs and Mr. Marxer. He stated that the conditions in which the disease was evident clinically could be described under five headings: acute and chronic diverticulitis without complication, acute and chronic perforative diverticulitis, and diverticulitis associated with stenosis. An analysis was given of eighteen cases under these five headings. Mr. Monsarrat expressed the opinion that in acute diverticulitis without complication no surgical treatment was indicated, and that patients suffering from chronic diverticulitis could be kept in health if they would submit to regular medical treatment. He described four cases of acute perforation of a diverticulum, and mentioned that this condition was treated on ordinary surgical principles. In regard to chronic perforation he held that the surgical treatment should be limited to opening and draining consequent abscesses. Lastly he described the treatment of diverticulitis associated with stenosis. Resection of the affected bowel was the operation of choice, but was only likely to be possible in a minority of cases. Operation might be rendered impossible by the situation of the stenosis or the extent of the disease in the bowel. The alternatives to resection were short circuit and colostomy. He had had one case in which colostomy was followed by subsidence of the disease and disappearance of the stenosis. In a second case a patient had remained well after a short circuit operation; a third case was reported of resection with cure.

### Reviews.

#### DUBLIN SURGERY.

COLLECTIONS of papers are often of more interest than systematic treatises, although they may not so thoroughly cover the ground; into short contributions on those subjects which interest him most a surgeon is likely to put the best outcome of his practical experience. The small volume now under notice is no exception to this generalization. In Sir WILLIAM WHEELER's *Selected Papers on Injuries and Diseases of Bone* the general medical public now has the advantage of reading the *Selected Papers on Surgical Topics*, which the author privately published, together with the results of the very valuable and outstanding experiences which he has had since the year 1916.

In his introductory essay on the necessity for team work and travel, the author strikes a note of enthusiasm and yet of criticism that will find an echo in many minds. His description of the career of a typical case of goitre, from

*Selected Papers on Injuries and Diseases of Bone.* By Sir William Ireland de C. Wheeler, M.D., F.R.C.S.I., F.A.C.S. Hon. London: Baillière, Tindall and Cox. 1923. (Demy 8vo, pp. xx + 145; 100 figures. 10s. 6d. net.)

its arrival at the Mayo Hospital in America to its final discharge "cured," is most vivid and convincing, but the reader is impressed with the magnitude of the problem which faces those who would try to make such a system universal. Still, as an advance towards the ideal of surgical treatment the work of the Mayos may well be set before us as an inspiration to further effort.

The Dublin school has always been well to the front in the treatment of fractures, and has contributed largely in the past to our knowledge of these injuries. Sir William Wheeler is a worthy representative of that school, and he has well maintained its reputation in the four lectures delivered two or three years ago in London at St. Bartholomew's Hospital on fractures of the lower extremity. These remind us of the great change which has come over our knowledge and our treatment of fractures of the pelvis, and of the important share which radiography has in that treatment, as in the cure of fractures in general; the section on the treatment of complications, such as injuries of the bladder and urethra, is particularly valuable. His remarks on the extension treatment of fractured femur are full of practical value. "Mal-union and non-union are due probably in 90 per cent. of cases to maltreatment. They are a reproach to surgery, and can always be avoided." In these words the author boldly throws down the glove and challenges those apologists who appeal to constitutional peculiarities or the interposition of soft parts as excuses. He follows Sir Robert Jones in discriminating between absolute non-union and delayed union, and in reserving operative intervention for the former condition only, after Thomas's "hammering and damming" method has had a proper trial. The comments on the treatment of fractured patella, of Pott's fracture, and those of the tarsus are all full of practical good sense.

The short paper on "sleeve" amputations and that on the treatment of Pott's disease are useful reminders of known methods. The same may be said of other articles in the volume. The work of American surgeons, and especially of the Boston school, has lately drawn attention to the sacro-iliac joint and its disorders, and it is interesting to read the opinions of a European author, who has recently surveyed American surgical practice, on this subject. Disease of this joint is, in Sir William Wheeler's opinion, far commoner than has been believed, and its early symptoms and signs can be, and ought to be, recognized more often than has been the case. He describes and freely illustrates the operation for laying open and draining this joint, which he has found practical. His fourteen points about bone grafts are of great value and should be noted by any surgeon who is thinking of performing a grafting operation and wishes to avoid disappointment.

In fine, there is very much in this book of great value and nothing that is not worth reading and marking.

### INFECTIOUS DISEASES.

Dr. E. W. GOODALL, who recently retired from the fever service of the Metropolitan Asylums Board, has employed his leisure in bringing out a third edition, under a somewhat different title, of the work on *Infectious Diseases*,<sup>2</sup> originally undertaken in collaboration with the late Dr. WASHBOURN. The considerable additions to our knowledge in the nineteen years which have elapsed since the appearance of the second edition have called for a very complete revision and enlargement of the work. The principal changes have been the addition of an introductory chapter on epidemiology and two new ones dealing respectively with epidemic encephalitis (including epidemic hiccups) and epidemic poliomyelitis, and the omission of the chapter on plague.

The book is well up to date and is of value, not only as representing the long and extensive experience of an acute observer, but also the work of one who is more familiar with the literature of the subject than the bibliographical references would suggest. We do not, for

instance, find a single reference to the literature of diphtheritic paralysis, only one in the few pages dealing with Vincent's angina, and only two on the section on nephritis, which date from 1889 and 1894 respectively, while first-hand references to Continental literature are particularly scanty.

A drawback to the publication is its high price, which is partly due to the large number of illustrations, some of which, as we remarked in our review of the second edition (*JOURNAL*, 1908, ii, 1813), might well have been omitted, especially those on scarlet fever, rubella, and the early stages of small-pox. The work, however, will be welcomed alike by epidemiologists and clinicians who desire authoritative information on the subject of infectious diseases.

### PHYSICAL DIAGNOSIS.

Books on physical diagnosis do not always make attractive reading, but the appearance of a ninth edition of Professor R. C. CABOT's *Physical Diagnosis*,<sup>3</sup> first published in 1905, shows that an account of what an experienced physician has found useful is more popular with the rank and file of the profession for everyday practice than a treatise containing all the described tests available for pathological investigation in the clinical laboratory, valuable as such a work may be for reference. Copiously illustrated as a book of this kind should be, attention may be specially directed to the admirable series of changes in the hands in various diseases, and to the photograph of twelve students listening at once to a chest by means of Bowles's multiple stethoscope, the limitations of which are pointed out. The text gains interest from references to the author's long clinical experience and to statistics of the incidence of various visceral diseases at the Massachusetts General Hospital; thus he frankly mentions that in two cases with well-marked Corrigan's pulse in life he "was confronted *post mortem* with a narrowed, rigid aortic valve." Dogmatism is useful for the student, and may be welcomed by some of more advanced age; writing on the supposed effects of tobacco on the heart, he quite definitely lays it down that there is not any cardiac abnormality or group of abnormalities that can be referred to the effects of tobacco alone, for almost always some other factor can be discovered in the background. The sections on the blood, tuberculosis, and the cardio-vascular system have undergone a good deal of revision, and the author's preface mentions particularly the addition of reference numbers corresponding to the Gamble-Cabot diagnosis records, a set of phonographic records taken in 1926 to illustrate the normal and abnormal heart sounds.

This edition, then, fully maintains the reputation of Professor Cabot as a clear, interesting, and honest-minded teacher of students, whether young or qualified.

### MILITARY PSYCHOLOGY.

Mr. F. C. BARTLETT, who is reader in experimental psychology and director of the psychological laboratory in the University of Cambridge, has written a book on *Psychology and the Soldier*,<sup>4</sup> which consists of selections from lectures delivered in connexion with a course of military studies for officers. He quite rightly points out that a psychological examination of the recruit is just as essential as the physiological or "medical" examination. This was made abundantly evident in the late war, where the failure to take into account the intellectual status of the soldier had lamentable consequences. It was surprising, moreover, when quite simple psychiatric examinations were instituted in the American recruiting camps, to discover how considerable was the proportion of recruits who were mentally unfit for military service. Useful as these tests as to mental capacity were, however, a large number of recruits who passed the examination in them broke down before reaching France with what have been well termed "anticipation neuroses." Most of these were temperamentally unfit to

<sup>2</sup> *A Text-book of Infectious Diseases*. Being the third edition of Goodall and Washbourn's *Manual of Infectious Diseases*. Revised and in large part rewritten by E. W. Goodall, O.B.E., M.D., B.S. Lond. London: H. K. Lewis and Co., Ltd. 1928. (Demy 8vo, pp. xvi + 718; 15 diagrams, 34 charts, 26 plates. 30s. net.)

<sup>3</sup> *Physical Diagnosis*. By Richard C. Cabot, M.D. Ninth edition, revised and enlarged. London: Baillière, Tindall and Cox. 1927. (Med. 8vo, pp. xxi + 536; 6 plates, 279 figures. 25s. net.)

<sup>4</sup> *Psychology and the Soldier*. By F. C. Bartlett, M.A. London: Cambridge University Press. 1927. (Cr. 8vo, pp. viii + 224. 7s. 6d. net.)

react to the army situation, and, as Mr. Bartlett observes, there is no test by which the defect of temperament can be discovered. As he well puts it, "By intelligence tests a man may be safely ruled out, but by intelligence tests alone a man cannot safely be ruled in." It should be said in this connexion that, in the experience of the reviewer, nearly all the men breaking down in the manner here described had been more or less inadequate in civil life; but this fact could only be elicited by full investigation of the social history.

In the development of his theme the author makes it clear that psychology may give valuable guidance in determining who is and who is not fit or adapted for the military life, in deciding what the fit person can justly be expected to do well, in training body and mind, in detecting and guarding against undue fatigue, and in taking precautions against nervous and mental disorders. Mr. Bartlett considers that training in psychology should be made part of any general scheme of preparation for a military career. He suggests that whether for war or for peace-time organization the psychologist who works in the academic laboratory should be asked to train the officer in methods and theory, and the officer having the necessary inside practical knowledge should then apply the methods and theories to his practical problems. This readable book affords an interesting instance of the value of vocational psychology as applied to a particular form of employment. It is not written for the medical practitioner, but we can recommend it to the officers of the army and naval medical services, to whom a knowledge of psychology cannot fail to be of considerable service.

#### NOTES ON BOOKS.

MR. SIDNEY SPOKES's biography of *Gideon Algernon Mantell* contains a sympathetic account of this pioneer of British geology, who started his professional life as a country doctor at Lewes, where he was born in 1790. While carrying on an extensive practice in this town and the neighbouring country he found time for epoch-making geological work, his first important publication being *The Fossils of the South Downs*. Shortly afterwards appeared in the *Philosophical Transactions* the account of the discovery of the iguanodon, in recognition of which he was elected F.R.S. at the early age of 35, when his nomination paper was signed by John Abernethy, his former teacher at St. Bartholomew's Hospital, and William Clift, curator of the Huerian Museum. In 1835 Mantell moved to Brighton, where he continued his practice in combination with his geological researches, and established a museum in his house; but after three years' stay in that town, where he found the medical profession far from sympathetic, he migrated to Clapham Common, where he remained for the next six years and found a much more congenial atmosphere, and was a frequent and highly appreciated lecturer at the local Athenaeum. The remaining eight years of his life were spent in Pimlico, where his time was occupied by his practice, his scientific work, and correspondence with contemporary geologists and palaeontologists, such as Owen, Lyell, Murchison, and Silliman. The whole of his professional life was a constant and heroic struggle against poverty and ill health, including rheumatism and a spinal complaint which appears to have been of the nature of osteo-arthritis. The work is illustrated by portraits of Mantell at various periods of his career and a photograph of his spine, which is preserved in the museum of the Royal College of Surgeons of England.

Mr. W. E. TAYLOR, who is professor of psychology in Smith College, must have expended much time and trouble in the compilation of his work entitled *Readings in Abnormal Psychology and Mental Hygiene*. The book is intended for the student of psychology rather than for the psychiatric student. As Professor Joseph Jastrow states in an introductory chapter, a knowledge of the leading facts and principles of abnormal psychology forms an integral part of the psychologist's training. It has a vital message also, he observes, for the practical-minded humanitarian, now conveniently known as a "social worker," in whose field devotion and high purpose require the support of authentic information and critical insight. The book consists of admirably selected extracts from the writings of well-known psycho-pathologists and psychologists. It includes a lengthy

bibliography. It will be useful as a book of reference for those for whom it is intended. It is scarcely suitable for consecutive reading, and it includes more than the average student of psychology could be reasonably expected to assimilate.

*The Creator Spirit: A Survey of Christian Doctrine in the Light of Biology, Psychology, and Mysticism* is the text of Canon C. E. RAVEN's Hulsean Lectures at Cambridge (1926-27) and the Noble Lectures at Harvard (1926). It contains an appendix on "Biochemistry and mental phenomena" by Dr. JOSEPH NEEDHAM, Fellow of Gonville and Caius College, Cambridge, who, after discussing the question whether any real relations between mental and physico-chemical phenomena are possible, and whether any are known or not, concludes that, though in the future an ever-increasing number of mental phenomena will receive satisfactory treatment in physico-chemical terms, there is nothing at all in this for the philosopher or the theologian to regret. In his eight lectures, the first four being based on his Hulsean and the remaining four on his Noble Lectures, Canon Raven treats the old problem of the conflict between science and religion in the light of modern knowledge and phases of thought with great skill, wide knowledge, and sympathy.

\* *The Creator Spirit: A Survey of Christian Doctrine in the Light of Biology, Psychology, and Mysticism*. By Charles E. Raven, D.D. With an Appendix on Biochemistry and Mental Phenomena by Joseph Needham, M.A., Ph.D. London: Martin Hopkinson and Co., Ltd. 1927. (Cr. 8vo, pp. xv + 310. 8s. 6d. net.)

#### THE OXFORD ENGLISH DICTIONARY.

OF the many good things the nineteenth century bequeathed to the twentieth through its belief in the capacity of individual initiative and enterprise to accomplish big undertakings is the *Oxford English Dictionary*. The first part was published on February 1st, 1884; the final sheets were returned for press by Mr. Onions on January 5th, 1928, and the last part will be published on April 19th. Seventy years ago the Philological Society, after considering and rejecting schemes for the production of supplements to standard dictionaries, resolved to accept the ideal of Trench, author of the *Study of Words*, then Dean of Westminster, to prepare and somehow to find means to print and publish "a completely new English dictionary." It was realized that the task would be very big, but no one then had any definite idea of what the cost would be in time and money. It proved to be in time fifty years of continuous labour by a succession of skilled editors, helped by large sub-editorial staffs, and £300,000 in money.

From the first it was realized that the kind of complete dictionary aimed at could only be produced through the co-operation of many voluntary contributors, and even in 1857 Trench had received offers from seventy-six. When the larger scheme was got fully under way the number had increased tenfold, and the maximum of over eight hundred, reached in 1881, was maintained to the end. They read books, copied out passages from them to illustrate meanings and shades of meaning, and verified facts; one contributor, Mrs. Moore, who came on an unusual word describing the seeds of a certain plant, procured some of the seeds, gummed them on her slip, and pasted transparent paper over them. Not all the contributors were British; there were a few in other European countries, and several in the United States. The slips, as prepared, were sent to the scriptorium or dictionary rooms, where they were pigeon-holed, with others referring to the same word, ready for the editor. Nearly all the work of editing has been done in Oxford. Herbert Coleridge, the first editor, was of Balliol, but had barely made a start when he died of consumption in 1861. Furnivall, who succeeded him, was keenly interested in the enterprise from the start, and remained a diligent contributor until he died, at the age of 85, in 1910. He was a lively writer and an exuberant controversialist, who must have been surprised to find himself a lexicographer. He was much concerned with the publication of early English texts, and for this purpose founded several societies. His hobby, if it may be so called, made him a very valuable contributor as long as he lived, and during the eighteen years for which he was editor he not only kept the project alive in its infancy, but watched over its adolescence by continuing the

\* *Gideon Algernon Mantell, LL.D., F.R.C.S., F.R.S.: Surgeon and Geologist*. By Sidney Spokes, M.R.C.S. London: John Bale, Sons, and Danielsson, Ltd. 1927. (Demy 8vo, pp. xv + 263; illustrated. 12s. 6d. net.)  
\* *Readings in Abnormal Psychology and Mental Hygiene*. Edited by W. E. Taylor. London and New York: D. Appleton and Co. 1927. (Demy 8vo, pp. xvii + 783. 16s. net.)

collection of material (slips) and organizing sub-editing. The dictionary reached early manhood when, in 1878, Dr. J. A. H. Murray, then a master at Mill Hill School, took the matter up, and a year later, acting on behalf of the Philological Society, signed an agreement with the Clarendon Press for the publication of the dictionary. From that time it has been an Oxford enterprise, having indeed had many connexions with that University all along. Murray began work at Mill Hill, where he erected a scriptorium, and was helped by his brother-in-law and one assistant. In 1885 he removed to Oxford, and put up another scriptorium in the garden of his house. There he worked for thirty years, until his death at the age of 80. In the interval he was joined by three other editors, who took over certain volumes from him: they were Dr. Henry Bradley, who was responsible for E, F, G, L, M, and parts of S and W (he died in 1923); Dr. W. A. Craigie, who joined the staff in 1897, and from 1901 until he went to Chicago to be professor of English in 1925 edited Q, N, R, U, V, and parts of S and W; and Mr. C. T. Onions, M.A. Lond., who began to help Drs. Murray and Bradley in 1895 and became an independent editor in 1914. He has worked in this capacity ever since, with the exception of two years, when he was engaged in producing the Oxford *Shakespeare Glossary* and editing *Shakespeare's England*. Another valuable by-product of the great dictionary was the *Concise Oxford Dictionary*, a scheme of Furnivall's, carried out later on by H. W. and F. G. Fowler; recently this was supplemented by the *Pocket-Oxford Dictionary* by the same authors.

The big Oxford Dictionary is a great achievement, and no other language possesses anything so good. We do not recall ever having gone to it without finding what we wanted, provided the word was in use when the volume in which it would find its proper place was issued. Though forty-four years is a short time in the life of a language, it is long enough for a good many new words to have come in. The Oxford University Press recognizes this, and announces in a special (February) number of its *Periodical* that a supplement is in preparation, "the main object of which will be to include words" (aeroplane and appendicitis are instanced) "which were born too late for inclusion." It is added, with fine liberality, that "copies of the supplement will be offered free to all holders of the complete dictionary."

Apart from its completeness, due to the inclusion of all words in use (not omitting scientific words) and of all words that ever have been used, even though now obsolete, the feature that gives the Oxford Dictionary its unique character is that it is constructed on a historical method. The first use of the word and its meaning at that time; and subsequent changes in meaning, and expansions and extensions of meaning, are all indicated and illustrated; the origin and etymology of the word also are explained and discussed, so that the book as a book makes fascinating reading—dangerously fascinating a busy man may sometimes find it. As the *Periodical* notes, a series of articles, "Medical Terms in the New English Dictionary" (as the book used to be called), was long an established feature of the BRITISH MEDICAL JOURNAL. They were written by the late Dr. J. A. Ballantyne of Edinburgh, who thus enabled our readers to keep track of the progress of the dictionary, and provided a gauge of its completeness in every direction. It may be too big and too dear (fifty guineas) for most private libraries, but no public, university, or college library can afford to be without it. Its motto might be "Thorough."

## INTERNATIONAL HYGIENE.

### THE LEAGUE OF NATIONS HEALTH ORGANIZATION.

WHATEVER the progress of the League of Nations in other respects, its Health Organization is advancing rapidly, and, according to the Information Section, may now be described as world-wide, not only in its membership, but in the range of its services. In addition to the fifty-five nations in the League, the United States and the Union of Soviet Socialist Republics have continued to take part in all the principal branches of the health work, and when members and corresponding members of the various com-

missions are included it can be claimed that there is no country of importance from the point of view of public health which does not co-operate. The information regularly received and disseminated by the service of epidemiological intelligence relates to three-quarters of the population of the globe. The bureau at Singapore receives information from 140 Eastern and Southern ports. It is proposed to set up a subsidiary centre of epidemiological information at Melbourne, and certain preliminary experiments have been made at Algiers for a similar centre in Africa.

Two general interchanges of public health personnel took place last year, one in Great Britain and the other in Germany; but only one—in India—is contemplated for this year. The public health courses organized in Paris and London in connexion with the system of interchanges are being continued. The Health Committee at its recent session decided to establish an international public health school at Rio de Janeiro, and an international school for infant and child hygiene at Buenos Aires. Research continued last year, under the League's encouragement, in a number of institutes on such subjects as antidyenteric and other serums, on tuberculin, and on the diagnosis and treatment of and immunization against scarlet fever. The insulin standard previously adopted has been distributed widely to the appropriate authorities, and a unit of insulin has now everywhere the same meaning. No difficulty has been experienced in producing samples of pituitary extract of uniform strength by following the same methods in their production. Standards for neosalvarsan and sulfarsenol have been prepared, and samples have been distributed to several countries for international trial and report. The Health Committee has decided to approach institutes concerned with the determination of blood-groups in order to suggest the international nomenclature.

The pox and vaccination was set up by 1925, and has now investigated a number of problems, especially concerning the preparation and examination of vaccine lymph. The cancer commission has completed its investigations into the differences in the incidence of certain forms of cancer in various countries. It has not been possible to draw any definite conclusions as regards racial susceptibility to cancer, since the term "race" is too vague, but certain facts have been brought out concerning the efficacy of early operation, and also the relatively greater liability to cancer of unmarried or barren women and mothers not nursing their children. The final report of the experts dispatched to equatorial Africa to inquire into the problems of sleeping sickness has been received, and the Governments which participated in the first international sleeping sickness conference in London in 1925 are being asked whether they would be prepared to send technical delegates to a second conference, with the object of studying the report and the recommendations. The malaria commission has presented its second general report, and a special meeting of the commission is to be held, to which malariologists from the United States will be invited, to discuss certain aspects of the problem so far as it relates to America.

The Health Committee has adopted the report of its opium commission describing eucodal and dicodide as products the manufacture and sale of which should be controlled by the convention, and this is being communicated to the Governments. The committee, on the initiative of the commission, has also reported to the Office International d'Hygiène Publique, which acts as an advisory council to the Health Committee, that dilaudide and the so-called esters of morphine, such as benzyl-morphine, should similarly come under the convention. A preliminary investigation has been made of social insurance in various European countries, and a joint international commission has been set up, representing both the public health services and the health insurance organizations, with a view to putting on a more systematic basis the haphazard efforts at prevention which have been found in the social insurance inquiry so far as it has proceeded, and to reduce the overlapping of public health services. An inquiry is also proceeding in certain countries, both of Europe and Latin America, into the medical and social causes of stillbirths and infant deaths. Finally, there is the question of leprosy, as to which there are proposals for the setting up of an international centre in Brazil, particularly for the elucidation of certain obscure questions concerning spread and treatment.

# THE HISTORY OF THE PHYSIOLOGICAL SOCIETY (1876-1926).

A RECORD OF FIFTY YEARS.

COMPILED BY

SIR E. SHARPEY-SCHAFFER, F.R.S.

It is generally recognized at the present time that the British school of physiology occupies a foremost position in the biological sciences owing to the outstanding character and varied nature of the notable discoveries that have been made by many workers during the last thirty years. A very remarkable record of achievement stands to the credit of British workers in many departments of physiology, and amongst these may be mentioned the great advances made in our knowledge of the functions of the nervous system; the nature of the activities of ductless glands; the physiology of the circulation, both in relation to the central pump and also to the part played by the peripheral and capillary circulation; the phenomena of nutrition, including not only the question of vitamins; but also the action of minute quantities of inorganic salts and the action of the sun's rays; and, lastly, fundamental researches on muscular activity and contractility generally, together with investigations on the electrical phenomena accompanying the activities of living matter.

This great progress has been due not only to individual discoveries of interest, but has depended still more on the discoveries being of such a character as to lead to the enunciation of general principles, thus tending to remove from physiology the reproach sometimes levelled at the biological sciences, that they consist mainly of a catalogue of facts or observations. The conceptions we now entertain as regards integration in the nervous system, the chemical correlation of organs and functions by means of hormones, are outstanding examples of the remarkable progress made by physiological workers in the last few years. Such discoveries connote a great deal more than the mere record of certain interesting experimental results, and they open up vistas of great promise for the future. Sir Edward Sharpey-Schafer, who has himself played no small part in this progress of physiology during the last fifty years, has compiled the history of a society—the Physiological Society—that is not only very closely linked with this development of physiology in the British Empire, but has also exerted a notable influence on this science wherever it is cultivated. It may, indeed, be claimed that this society, founded only some fifty years ago, has had an even wider influence, as it has served as the model on which a number of other vigorous and younger societies have been moulded, and these, in their turn, have exerted no small influence on the progress of biological and medical science.

The Physiological Society owed its origin not only to the

awakening, after a long sleep, of physiological studies in England, under the influence of the inspiring teaching of William Sharpey at University College, London, but also, and very largely, to the anti-vivisection agitation that arose in the early seventies as a sequel to the commencing development of physiological investigations at that time. In 1875 a Royal Commission was appointed to inquire into these matters, and in due course reported, and subsequently an Act of Parliament was passed for the purpose of regulating experiments on living animals. In consequence of the report of the Royal Commission a meeting was held at 49, Queen Anne Street on March 31st, 1876, at the request of Dr. John Burdon-Sanderson, and was attended by nineteen persons interested in physiology, including Sharpey, Huxley, Michael Foster, George Henry Lewes, Francis Galton, G. J. Romanes, Francis Darwin,

and two who happily are still with us, E. A. Schafer and David Ferrier. On the motion of Dr. Michael Foster, seconded by George Henry Lewes, it was resolved:

"That an association be formed, under the name of the Physiological Society, for promoting the advancement of physiology and facilitating the intercourse of physiologists."

The record of the work of the society during the fifty years of its existence, as shown by Sir Edward Sharpey-Schafer, reveals how admirably it has fulfilled the objects expressed in this resolution. It is only necessary to allude to two facts in proof of this. The records of the society show that every really notable discovery in physiology made by workers in this country during the last fifty years has, in the first instance, been brought before this society, and thus it has undoubtedly fulfilled its obligation in promoting the advancement of physiology. Further, the well-known spirit of camaraderie that inspires the working physiologists of this country is proof in itself of the good the society has done in "facilitating the intercourse of physiologists." In later years

this side of the society's activities was extended, with manifest advantage, far beyond the confines of these islands, and international relations were entered into and led to much friendly intercourse between foreign and British physiologists.

The great success of the society in achieving its aims was doubtless due to several causes; thus many of the men who played so large a part in its foundation were animated by broad views in biological matters, and were concerned in placing physiology on a secure basis as an independent science and not merely as a scientific auxiliary to medicine. Huxley, G. H. Lewes, Francis Galton, G. J. Romanes, E. Ray Lankester, Thistlethwaite, Dyer, are names of men distinguished by their work for biology, and all of these took an active part in the foundation and in the early work of the society. In Sharpey, Burdon-Sanderson, and Michael Foster the society had the support of the three men to whom the development of physiology in this country, both as regards teaching and as regards the inspiring of research, was

Photograph by]

[A. Swan Watson, Edinburgh.

SIR EDWARD SHARPEY-SCHAFFER, F.R.S.,

Professor of Physiology in the University of Edinburgh.

mainly due. All three laid the foundations of modern physiology in this country in University College, London, where Sharpey was professor from 1836 until 1874, and Burdon-Sanderson, under Sharpey's influence, began experimental investigations in 1866 and succeeded Sharpey in the chair of physiology in 1874. Foster, who gave up general practice at the instigation of Sharpey, and because, as he once told the writer, he had come to the conclusion that no sane man could make a diagnosis in medicine—such were the contradictions of medical teaching in his time—became the teacher of practical physiology and histology in 1867. Subsequently (in 1870) he went to Cambridge, and there built up a school of physiology that has achieved results of the first importance, and even as early as 1876, when the Physiological Society was founded, had already amongst its workers such men as W. H. Gaskell and J. N. Langley.

Although the society was fortunate in having amongst its founders men of such wide outlook, of such outstanding intellectual ability, and of such remarkable personality, nevertheless this was by no means the only factor in determining its success. Much of this success is to be attributed to the rules and remarkable constitution of the society. Thus at the outset the membership was limited, and the members were for the most part active working physiologists, but they had the right to introduce guests.

It is also interesting to note that the society was originally intended to be a dining club, and one rule lays down that the meetings shall commence with dinner at the early hour of 6 p.m., later altered to 7. Another rule of some importance provided that at each meeting one member should be elected, on the motion of the secretary, to act as chairman. Hence the society never had an official head or president, and this may have had some influence in making the proceedings, even in later years, less formal than is usually the case in scientific societies. It has been the custom to adhere to the rule that all business of a formal nature should be transacted at the dinner meeting. The inaugural meeting, with Dr. Michael Foster in the chair, was held at the Criterion Restaurant on May 26th, 1876, and twenty-two members were present with fourteen guests. Amongst the latter were Donders of Utrecht, Marey and François Franck of Paris, and Lovén of Stockholm, together with William Bowman, W. B. Carpenter, and William Marcet. William Sharpey and Charles Darwin were the first two honorary members of the society, and Francis Galton, George Henry Lewes, and Francis M. Balfour all attended the first meeting.

In the first few years of the life of the society, as is seen from Professor Sharpey-Schafer's interesting narrative, the main business seems to have been to keep a watchful eye on the proposed legislation and on the administration of the Act regulating experimental work on living animals. Further, the society gave advice with regard to the allocation of the Government grants administered by the Royal Society for the furtherance of physiological research. In the records of these awards, preserved in the minutes of the society, it is interesting to see the recommendations as to grants that have enabled workers to carry through successfully researches that have become famous with the lapse of time. Thus in 1876 there is the record of a recommendation of a grant to Mr. G. J. Romanes to carry on "observations on the locomotor system of the medusae," and another with reference to work by Mr. Langley on "The action of the sympathetic on the submaxillary gland."

The international relations of the society were marked even in these the earliest days of its life, as is shown not only by the number of foreign guests often present at the meetings, but also by the minutes of the year 1878, which contain the record of a letter of sympathy addressed to the Société de Biologie on the occasion of the death of Claude Bernard. A resolution was also passed in this year recording regret at the death of George Henry Lewes, one of the original members, and one who took very great interest in the development of physiology in this country, and in whose memory the well-known George Henry Lewes studentship in physiology was subsequently founded.

In the years 1879 and 1880 a new development took

place that ultimately led to the full realization of the wishes of the founders as to the promotion of the advancement of physiology. In 1879 a special afternoon meeting was held at King's College to hear an address by Professor Arthur Gamgee on "Old and new experiments relating to fibrin ferments, with a demonstration of the rapid coagulating action of a solution made by extracting washed blood clots with 8 per cent. NaCl solution." This meeting was attended by eight members and one visitor. In 1880 the scientific meetings of the society were definitely commenced; the first was held on December 9th, 1880, in the physiological laboratory of University College, London, under the chairmanship of Professor Burdon-Sanderson. Eighteen members and three visitors were present, and amongst the visitors was Sydney Ringer, who at that time was actively engaged in his work on the action of inorganic salts on living tissues, especially the heart, that has made his name famous. He did not become a member of the society until 1884. From this time onward, scientific meetings were held in the afternoon prior to the dinner, at regular intervals, in the laboratories of colleges, medical schools, and at the Universities of Oxford and Cambridge. In later years such meetings were held further afield—for example, in Edinburgh and at many provincial universities—but wherever they were held they retained their fundamental and original characteristics, and it is to these, perhaps, rather than to anything else, that the society owes its most remarkable success in promoting the advance of physiology and thus fulfilling the aims, not only of its founders, but also those of all active workers in physiology.

The meetings of the Physiological Society have always been remarkable for the interest awakened in those present in the subjects brought forward for their consideration, and also for the freedom and candour of all discussions that took place. The remarkably "live" character of the meetings was due to many causes, but mainly to the following. Practically all members were actively engaged in prosecuting investigations of one kind or another, and the communications made to the society were generally of the nature of actual demonstrations of some experimental result recently obtained by the investigator. In fact, one of the rules laid down that demonstrations should always have priority over oral communications, and hence the meetings often consisted only of a series of demonstrations. Thus physiologists had often the opportunity of witnessing the progress of researches and not simply listening to the recital of a piece of finished work. Inasmuch as there was no published record of any discussion that took place, criticism was not only often remarkably free and outspoken, but still more often it was most beneficial, and many workers must look back with pleasure and thankfulness to the assistance they often received from others more experienced who witnessed and criticized their experimental results. Such was the friendly feeling amongst the members that no one hesitated to bring forward striking experiments obtained, it may be, at an early period of an investigation and before work had advanced to an extent sufficient to justify conclusions. No claims of priority were either advanced or allowed on the mere basis of these experimental demonstrations, and it is difficult to over-emphasize the valuable results that were obtained by the steady following of such methods. All the members felt that they were in active contact with the most recent additions to knowledge in the making, and this led to an enthusiasm for physiology that has had much to do with its progress during the last fifty years. At a later stage in the history of the society the rapid progress of physiology led to the publication by the society of short abstracts of its proceedings, and recently the control of the *Journal of Physiology* has become part of its work, and thus the influence of the society has been still further extended.

Sir Edward Sharpey-Schafer, in his full and interesting account of the society, deals not only with its work as a whole, but has greatly added to the value and interest of the record by including in it short accounts of biographical detail of a very large number of the members; and in the case of deceased members he has been successful in obtaining their portraits. In fact, the volume may be

regarded as a biographical dictionary of the physiologists of this country for the last fifty years, and must for this reason have a real permanent value, quite apart from its interest in many other respects.

The author has dealt with a subject of no little interest in the history of science and of scientific medicine in this country, and has shown in an attractive manner the profound influence that a working society, founded and conducted on sound lines, can exert on the advancement of science and the progress of knowledge.

JOHN ROSE BRADFORD,

M.D., F.R.S.,

President of the Royal College of Physicians of London.

## NATURAL CAPACITY IN THE POPULATION.

GALTON LECTURE BY MR. C. J. BOND.

THE Galton Lecture for this year was delivered at the Rembrandt Hotel, South Kensington, before the Eugenics Society by Mr. C. J. BOND, C.M.G., F.R.C.S., of Leicester, on February 16th. It was preceded by a dinner, which was presided over by Major LEONARD DARWIN, Sc.D. It was well attended, and the audience included many ladies. Among those present were the Bishop of Winchester, Lord Dawson of Penn, the Dean of St. Paul's, Dr. Fremantle, M.P., Dr. H. H. Dale, Secretary of the Royal Society; Sir Arthur Keith, F.R.S., President of the British Association; Sir William Beveridge, Director of the London School of Economics; Dr. C. S. Myers, F.R.S., Director of the Industrial Institute of Psychology; and the Right Hon. William Graham. The subject of the lecture was "The distribution of natural capacity in the population," and the conclusion to which the lecturer led up was that there was a need for a national stocktaking, or a census of the people which would reveal the mental qualities.

### Racial Decline.

In the opening part of his lecture Mr. Bond contended that civilization and races, like individuals, passed through successive stages of growth, maturity, and decline. The life of a nation was the expression of hereditarily transmitted racial qualities of mind and body. This national life was renewed from below, and depended largely on the mental and bodily qualities of the citizens in the large middle section of society. Under modern conditions there was a strong and growing tendency for the lowest social groups—those including the mental defectives and individuals of a low mental grade, the habitual pauper, and the innately criminal classes—to contribute an undue proportion to the numbers of the population. Such a condition in social, as in individual, life was abnormal, and indicated the commencement of racial decline. Although racial decline was the direct biological effect of breeding from degenerate and inferior stocks, there was also an indirect sociological effect of much importance. The burden of the economic support of these degenerate groups was largely borne by the more capable citizens above, who were themselves thus handicapped in rearing their own families. If, in addition, the ability of these worthier citizens to bear this burden was also depreciated by inter-breeding with inferior stocks, a double injury was inflicted on the nation.

Evidence pointing to deterioration in the mental and bodily qualities of the British people was to be found in the numerous inquiries and official and unofficial reports which had appeared in recent years. The conclusion to be drawn was that there was an urgent need existing for a national stocktaking, or a census of the people which would reveal quality as well as numbers.

The fact that mental qualities, intellectual, temperamental and moral, would no doubt be of increasing importance in the civilization of the future made it essential to include these qualities in the proposed inquiry. Though the ultimate nature of neural, as of psychical, energy was unknown, yet something had been ascertained as to the conditions under which neural energy operated. That which was transmitted in heredity was the neural or physical mechanism of varying degrees of organization, through which, or in which, the psychical phenomena became manifest.

### The Differential Birth Rate and Conception Control.

The essential points in regard to the relative fertility of different social groups in the population to-day from the eugenic standpoint were: (1) That the birth rate was lowest in the upper levels of society and in the professional and salaried groups in the large middle section of the population, and that

it rose as a descent was made to the ranks of unskilled labour. (2) This alteration in the previous normal incidence of fertility had grown rapidly in recent years. (3) It was operating on a very large scale, and must, if continued, have a very serious influence on the whole population. The practice of contraception was to-day more prevalent among the educated upper and middle classes, and less prevalent in the unskilled labour groups, while it was practically absent in the lowest degenerate sections of society. Birth control, then, as at present practised, was undoubtedly exercising a dysgenic influence on society. The remedy, however, did not consist in the curtailment of knowledge, but in its spread, on wise lines, to all sections of the population, poor as well as rich. This spread of knowledge in regard to birth control must also include instruction in the duty of adequate parentage in the case of married persons of sound stock and healthy constitution.

### The Kind of Census Needed.

An inquiry into the distribution of natural capacity in the population should be included in the census schedule for 1931 by asking questions of genetic or racial importance as to size of family, etc., which were in the schedule for 1911, but were omitted in that of 1921. Certain data of genetic importance should also be added in the system of birth certification and registration. In addition to such information as could be obtained from a census of the whole population a more intensive inquiry might be carried out into certain representative samples taken from the children of school age, and from industrial workers, who might be examined under the Insurance Act at the time of entrance into industrial life, and periodically afterwards. The object of the inquiry must be to reveal quality as well as numbers, and to show in what sections of the population civic was associated with racial worth.

### Eugenics and Medicine: Civilization of the Future.

Much advantage to eugenics (Mr. Bond continued) and to medical science would accrue if the interest and active co-operation of the medical profession could be enlisted in the study of genetic problems. Medical men possessed unrivalled opportunities for observing and recording the hereditary transmission of mental and bodily characters from parents to offspring and from generation to generation, but at present this valuable knowledge was largely lost to the nation. Medical science would also greatly gain by further research into the influence of the hereditary factor in disease. But in order to bring about this active co-operation between medicine, genetics, and eugenics a different outlook must first be established towards genetic problems in all bodies and institutions concerned with the education of medical students.

It might be objected that since no one knew what human civilization and human life would be like in the future, any attempt to produce, along eugenic lines, mental and bodily qualities suited to the future environmental conditions must necessarily fail. It might, however, be predicted that human evolution would proceed along psychical lines, and that the human environment of the future would be one in which brains counted for more than muscle. In such an environment intellectual and moral qualities, character, personality, and capacity for citizenship would be very important features in the equipment of the future citizen, and there would be no room, at any rate, for mental deficiency.

### Practical Conclusions.

If such an inquiry or national stocktaking as was suggested should point to some deterioration in the population, then, among the remedial measures, the first place must be given to education. It was only by education along biological lines that a sound public opinion could be formed concerning eugenic problems, or that a racial conscience could be aroused. Segregation along biological lines must be brought about between the fit and the degenerate sections of society. The mentally defective groups, including the habitual pauper, the inebriate, and the innately criminal class, must be segregated during the reproductive period of life, while in some cases, after careful inquiry, expert advice, and judicial sanction, sterilization might be necessary.

Although man had grown but little in mental stature during historic times, there were encouraging signs for the future. The power to control not only the environmental conditions in the outside world, but also the quantity and eventually the quality of human life produced, would enable civilized man to change human nature and to raise mental and moral capacity to a higher level. But this artificial selection under human control must be of the right kind, and it must be exercised in the right way—namely, along lines calculated to promote true racial welfare. At the present time much legislation and many sociological methods for improving the conditions of life were not founded on sound biological principles. The aim of the eugenist would be to bring about a wider outlook and a sounder public opinion concerning racial problems.

## CLINICAL TEACHING IN MEDICINE.

THE eighth series of *Methods and Problems of Medical Education*,<sup>1</sup> brought out at intervals since the autumn of 1924 by the Division of Medical Education of the Rockefeller Foundation, is a mine of information on the methods of teaching and equipment of medical students in various centres in parts of the world as far asunder as Pekin and Paris. Attention may well be drawn to some of the information given in the eleven articles on the teaching of medicine and the lessons to be learnt from them, leaving those on surgery, gynæcology, and pediatrics, and the considerable series on cardiological clinics, for later study.

The first two articles, by Professor A. Chauffard and Sir Archibald Garrod, are of the nature of general surveys of the teaching of clinical medicine in France and in England, and necessarily touch on the historical aspect of clinical teaching in order to show how the present plan has been evolved. In France the oldest medical faculty is that of Montpellier, where from the thirteenth century students followed the practice of medical men, though it was not until the fifteenth century that it became a university. In Paris chairs in clinical medicine were not instituted until the end of the eighteenth century, Corvisart giving his first clinical lecture at the Charité on May 20th, 1799. Professor Chauffard points out that medical students, while spending the first two years in working at anatomy and physiology, attend the hospitals in order that familiarity with the symptoms of disease and their education as medical men should begin as early as possible. During the first year they all follow the clinical professors' visits, but in the subsequent years they have the advantage of being taught in small groups by the "professeurs agrégés" and the hospital physicians, thus, to some extent, resembling the British routine. Sir Archibald Garrod outlines the history and evolution of clinical teaching in this country from the sixteenth century until the establishment of the professorial units in 1919. He describes the advantages and possible drawbacks of these units with complete detachment, as the first director of the professorial unit at St. Bartholomew's, impartially indicating what the students gain from being taught by the ordinary physicians, with their various interests and experience. He reminds us that the clinical clerks and dressers of to-day are the direct successors of the apprentices and pupils of the past. Turning to a rather different aspect of the subject, he recalls that the medical schools of the new universities have grown out of pre-existing medical schools, so that the universities have not had the opportunity of establishing and organizing medical schools from the start with a new hospital untrammelled by ancient custom and vested interests; the reverse is very frequently the case in the United States.

It is interesting to contrast the English and foreign

<sup>1</sup> *Methods and Problems of Medical Education*. (Eighth series.) Division of Medical Education, the Rockefeller Foundation, New York. 1927. (Imp. 8vo, pp. 372; illustrated.)

medical schools as regards the clinical years when students come into intimate contact with patients by holding clinical clerkships. In their account of the arrangements at the Second (Cornell) Medical Division of the Bellevue Hospital, New York, Drs. Eugene F. Du Bois and P. Reznikoff state that in American medical schools the clerkships are usually reserved for the final year, by which time the student has almost completed his period of systematic training and is about to become his own instructor. Professors Henry Christian, J. H. Means, and F. W. Peabody, describing the teaching at Harvard, say that after one and a half academic years of instruction, intended to give the student a knowledge of clinical medicine and a drilling in the methods used in its practice, as well as information about the more important data of medical diseases, the final year sees a complete change in the routine; the student is then put in full contact with the patients, and applies the methods he has previously learnt to the examination and consecutive study of cases in the wards and out-patient departments. According to the professor of propædæutical clinical medicine and general pathology in Amsterdam, Dr. I. Snapper, the students there, after passing their examination in anatomy and physiology, attend for two years demonstrations on cases, and take practical courses in the methods used for investigating them; after a further examination their practical education begins, and they work in the wards and out-patient rooms for several months as so-called co-assistants. A special feature of medical teaching in Holland is that during the two years devoted to normal anatomy, physiology, and histology, a theoretical introduction to the clinical sciences is given by means of a course in general pathology.

It must be admitted that, just as our students concentrate on physiology and anatomy before entering the wards and out-patient departments for continual contact with the sick, so, on strictly consistent and logical grounds, it might be argued that they should acquire a thorough working knowledge of morbid physiology and morbid anatomy and of the methods of clinical investigation before being turned loose among patients. This, however, is completely foreign to our system of beginning clinical work directly after the examination in anatomy and physiology has been passed, and picking up while thus occupied a knowledge of pathology and of clinical methods. The advantage of the British method—a continuation, as Sir Archibald Garrod points out, of the old apprenticeship plan—is that the clinical instinct, difficult as this important faculty may be to define, but nevertheless invaluable, is thus engendered. Continued and close study of patients is an education which, when combined with a good knowledge of laboratory work, makes the best type of clinical physician. It has long been recognized in this country how difficult it is to carry out successfully what is *a priori* the proper plan—namely, to teach students auscultation and percussion before they begin to deal with medical patients. Professor F. R. Fraser, in giving an account of the Department of Medicine at St. Bartholomew's Medical College, says that a few years ago an attempt was made to set aside a period of three months, immediately before the clinical appointments, for introductory courses in pathology, clinical medicine, and surgery, the course in medicine including instruction in history-taking and physical examination. But this obvious dissociation of the instruction in bedside methods from the actual responsible clerkship proved unsatisfactory, and at the present time this course is

given at the beginning of the first in-patient clerkship. The usual order in which these medical appointments at St. Bartholomew's Hospital are held is: three months' in-patient clerking under one of the ordinary physicians, then three months as pathological clerk to a "firm," three months' out-patient clerking, and a further three months' in-patient clerking—in the last year—in the professorial unit.

Thus it may be said that the British plan of picking up clinical methods and pathology while in daily and hourly contact with patients lacks the advantage of coming fully armed to the task of solving a pathological problem, which should be provided by the American plan of preparation for clinical clerkships. But, on the other hand, the ideal medical man cannot be rapidly made out of a well-drilled laboratory pupil; he requires experience, which develops the intuition and human touch that nothing else gives in quite the same degree; and certainly it was these qualities that made the great clinical physicians of this country in the past.

### CRANIAL INCISIONS.

THERE will ever be a certain fascination for the surgeon in the problems of surgical approach, and that to the skull is one of the most difficult. In other regions the actual approach, the exposure, is made through soft tissues, and is a matter of minutes only. None the less, surgical technicians have found much to absorb their interest, and to exercise their ingenuity, in the matter, for instance, of opening the abdomen or of exposing the hip-joint; and it would be not unfair to say that on occasion some warmth has been generated in the defence or the criticism of some particular method. The fundamental issues are the same in the case of the skull, but here the approach to the brain is physically more difficult.

The ideal before the surgeon in making all incisions is that they should be relatively atraumatic, that they should be speedy, that they should give good exposure of the parts, that they should be easily and firmly closed at the end of the operation, and, lastly, that they should remain closed. The ideal incision is that which makes the operation easy, for what is easy is generally safe; and while it is not always true that that which is difficult is unsafe, there must always be a greater element of risk in it.

The mechanical difficulties of the free exposure of the brain add only a small amount to the risks of cerebral surgery, for the whole essence of neurological surgery lies not so much in what is done to the skull as in what is done to its contents. It has, we think, often been a source of wonder to the general surgeon that the neurological specialist should be so indifferent to the means he uses for opening the skull. If the surgical onlooker sees a sequence of half a dozen men at work he will probably see half a dozen methods, all different in some degree; and the plain fact, as it seems to us, is that it does not very much matter. The occasional operator on the skull is apt to be much more interested in the boring of the bone and in the methods of cutting it than in the later stages. It has been said, a little unkindly perhaps, that operators upon the head may be divided into two classes, skull surgeons and brain surgeons, of whom the former vastly outnumber the latter. To cut a disc out of the skull with a trephine without opening the dura gives an enormous pleasure and feeling of importance to senior residents in hospitals. Just why this should be so it is not very easy to understand; perhaps

it is because they may have very nearly done something important without incurring the risks that something really important might have entailed.

We hope there is no need for us to say that in making these few remarks it is very far from our intention to belittle the importance of Mr. H. S. Souttar's new instrument. His craniotome—described in the Hunterian Lecture, printed with illustrations at page 295 this week—is the most valuable and most rapid bone-flap cutter that has yet been invented. The danger is that now he has made the approach to the brain a little easier the generality of surgical folk may think that one of themselves *plus* a craniotome equals a neurological surgeon. The circular saw we are less impressed with; there is, of course, nothing new in the idea of using a saw of this type; the ingenuity lies in the transmission system, an engineering feat of no small magnitude. The less mechanically minded of surgeons are grateful to such men as Mr. Souttar for solving their problems for them. We have not seen Mr. Souttar use the circular saw, but we well recollect seeing a New York surgeon take a good hour to cut a bone flap with an Albee saw or some modification of it. Such constant soundings had to be taken that progress was most tedious. The Souttar craniotome, on the other hand, seems to be almost fool-proof, and will probably supersede other implements. Its disadvantage, we think, is that it cuts a circular flap. This is not a bad shape in the parietal region if made large enough (Mr. Souttar's advice that it should be three or four inches in diameter is a conservative measurement), but on many occasions the rectangular flap is a more useful shape, especially in the frontal region.

Mr. Souttar's recommendations for occipital exposure will be read with the greatest interest by all whose special hobby this is, and he appears to have made a most valuable contribution to the subject. Experience is the only test, and we shall follow the results of extended experience with his instrument with lively curiosity and appreciation.

### TESTIMONIAL TO SIR DAWSON WILLIAMS.

SOME of our readers will be aware that preliminary steps are being taken to promote a testimonial to Sir Dawson Williams, who lately retired from the Editorship of the *BRITISH MEDICAL JOURNAL* after thirty years in that position and nearly fifty years' close connexion with the editorial work of this *JOURNAL*. There is a widespread feeling that the occasion should not pass without some recognition, from the profession as a whole, of his long and distinguished services to the science and practice of medicine. We understand that it is accordingly proposed to issue a general appeal, and to send to the medical press a first list of supporters for publication on March 10th. Those wishing to be included in this list are invited to send their contributions, not later than March 3rd, to Sir StClair Thomson, who has been asked by the provisional Executive Committee to act as honorary treasurer. Though the committee does not wish to limit the amount of individual donations, it hopes that the sum eventually received will include a large number of contributions of two guineas or less, and so represent the profession generally. Cheques should be made payable to Sir StClair Thomson and sent to 64, Wimpole Street, London, W.1, and the envelopes marked "Dawson Williams Testimonial." We feel sure that this proposal to honour one who has served the British Medical Association with such outstanding ability and devotion will commend itself to members in every branch of professional life.

## EPIDEMIC ERGOT POISONING IN ENGLAND.

EPIDEMIC ergotism is well known as an affliction of mediæval Europe, but it has been generally assumed that this is one of the plagues that the advance of civilization has banished. It will therefore come as a surprise to many to read the account of a recent epidemic of ergot poisoning described by Drs. Robertson and Ashby in our present issue (p. 302). This epidemic has occurred, moreover, not in the wilds of Eastern Europe, but in Manchester. Records of epidemic ergotism date back to the ninth century, and all through the Middle Ages terrible outbreaks of poisoning occurred amongst rye-eating populations after wet summers. Large numbers were killed in these epidemics, and many only survived after losing the greater portion of their limbs from gangrene. Before the advent of steam transport the unfortunate inhabitants of districts which depended on rye often found themselves faced, after a wet summer, with the alternative either of starvation or of poisoning from the consumption of ergotized rye. The improvement of communications due to the advent of steam transport naturally reduced the frequency and severity of such epidemics, but it did not abolish them, for several have been recorded during the last half-century in Eastern Europe. Last summer provided the optimum conditions for the growth of ergot in rye, and no doubt ergot was very prevalent in the grain. It is, however, rather a shock to learn from the present report that grain containing 1 per cent. of ergot has been in use in England as human food. The pharmacology of ergotism is somewhat obscure. Ergot contains about one part per thousand of two specific alkaloids—namely, ergotoxine and ergotamine—and these can cause high blood pressure, gangrene, and abortion. The symptoms described in the present outbreak—namely, disorders of sensation, twitchings of the limbs, and staggering gait—are more associated with the spasmodic type of ergot poisoning (as opposed to the gangrenous type), and the active principle in the former is unknown. Fortunately, the cases in the Manchester epidemic were relatively mild, but the event is a curious example of the way in which an obsolete and half-forgotten danger to health may be revived by some change in conditions. The fact that the eaters of black bread contracted ergotism and the eaters of white bread escaped shows that there is, at any rate, one sound reason for the popular prejudice in favour of the latter.

## THE THYROID AND MENSTRUATION.

AN example of the functional relation which exists between endocrine glands is afforded by the thyroid and the ovaries, as evidenced by the frequency of menstrual irregularities in affections of the thyroid. Disorders of menstruation are also not uncommonly observed in other diseases in which metabolism is affected—as, for example, in diabetes and tuberculosis. In these conditions, however, menstruation is usually suppressed, but in diseases of the thyroid either suppression or excess of menstrual activity may be found. This was thought to be dependent upon the degree of activity of the thyroid, but a study of the literature shows no general agreement. Thus, either amenorrhoea or menorrhagia has been recorded as being present both in myxoedema and in exophthalmic goitre—conditions which exhibit the two extremes of abnormal function of the thyroid. Drs. H. Gardiner-Hill and J. Forest Smith have recently made an investigation in the Medical Unit of St. Thomas's Hospital, to ascertain the type of menstruation occurring in a large series of cases of diseases of the thyroid of different grades.<sup>1</sup> In this investigation they examined more than 300 patients, including 9 cretins, 100 adolescent goitres with varying degrees of thyroid function, 86 cases of exophthalmic goitre and hyperthyroidism, 41 of

myxoedema, 24 of parenchymatous goitre, and 22 of simple adenomatous goitre. In order to provide confirmatory evidence of the degree of thyroid activity estimations of basal metabolism were also carried out. Turning to the results obtained, and taking into consideration the whole series of cases investigated, it was found that menstruation may or may not be affected in these diseases, but that when menstruation is affected the alteration tends to be in a uniform direction. The degree of thyroid activity and the type of menstruation vary inversely, as there is often a tendency to menorrhagia in hypothyroidism and to amenorrhoea in hyperthyroidism. The observations of Gardiner-Hill and Forest Smith may be summarized as follows: In cretinism the onset of menstruation is usually delayed, and if not adequately treated may never appear, but if suitably treated menstruation tends to be regular and normal. In adolescent goitre, with no signs of thyroid disturbance apart from the goitre, menstruation is usually normal; with hyperthyroidism the menstrual periods are often delayed, scanty, and irregular, and with hypothyroidism menorrhagia occurs. In exophthalmic goitre menstruation may be normal, but in the more severe cases the periods are scanty and irregular, and in the most severe cases amenorrhoea is generally present. In myxoedema before the menopause menorrhagia is commonly present. The impression that myxoedema is sometimes accompanied by amenorrhoea is due to the fact that this disease frequently develops after the menopause. Finally, in parenchymatous and simple adenomatous goitres there is usually no disturbance of menstruation, but in patients with hypothyroidism menorrhagia has been observed.

## TATTOOING AND REMOVAL OF TATTOO MARKS.

THE ancient practice of tattooing, which probably dates back to the prehistoric cave-dwellers, and has reached its highest development in the islands of the South Pacific and in Japan, presents many points of medical interest. In certain lands it is employed as a form of preventive medicine in virtue of special designs warranted to avert the evil eye, while, on the other hand, in modern medicine many examples have been recorded of patients infected with divers diseases at the hands of those who practise this form of decorative art. Dr. Marvin D. Shio, in an interesting article<sup>1</sup> on the subject, mentions that Bercheron in 1862 was able to report no fewer than eight deaths as the direct result of tattooing, with many other cases of serious septic infection. Leprosy and tubercle have several times been transmitted in this way, and syphilis quite frequently; a single operator with mucous tubercles in his mouth is said to have infected as many as nine patients in a single day. Modern antiseptics have much reduced the risks of tattooing, as of other and more useful operations, but since the practice is peculiarly attractive to the denizens of the "underworld," and is often carried out on alcoholic subjects by alcoholic operators, the attendant hazards still remain considerable. But the commonest problem associated with tattooing to be presented to the surgeon is that of the removal of the marks. It is a problem which has scarcely yet been satisfactorily solved. Tattooers have therefore been in the habit of doing what may be considered the next best thing—namely, the bowdlerization of obscene designs or the concealment of some mark of identification by the superposition of something new on the same site. Surgical, electrolytic, and chemical methods have all been tried in the effort to secure complete removal without a scar. Except in the comparatively rare instances when the design can be excised and the wound sutured or even skin-grafted, the resulting scar is always a serious matter, but Dr. Shio has been able to obtain good results by the method of Variot, which

<sup>1</sup> *Journ. Obstet. and Gynaecol. of the British Empire*, Winter Number.<sup>1</sup> *Journ. Amer. Med. Assoc.*, vol. 90, p. 94.

consists of tattooing into the design a 50 per cent. solution of tannic acid in water. The area to be treated is painted with the tannic acid solution and tightly stretched so as to minimize the pain to the patient, and tattooed closely all over. To accelerate the process several needles—for example, ten—can be used simultaneously if mounted in a convenient manner. From time to time an assistant adds fresh tannic acid, so that the tattooing is always done through the solution. When all is complete the whole area is grey and swollen and the pigment almost obliterated. It is then rubbed over with a stick of silver nitrate, and a heavy black deposit of silver tannate is formed, which extends right down to the corium where the original pigment was laid down. After fifteen or sixteen days a slough, like a thin piece of leather, comes away, leaving a thin new layer of epithelium beneath it. This gradually assumes the appearance of the normal skin, and in favourable cases no scarring persists. If, however, the hair follicles have been destroyed within the tattoo mark there will be some scarring. Dr. Shie considers that the best field for this method lies in the removal of accidental tattoo marks such as are left by powder explosions depositing carbon. But he owes his very considerable experience of tattooing and its removal to the fact that he has been connected with the Marine Hospital of Cleveland, frequented by sailors—a folk among whom the practice is notoriously popular.

#### EPIDEMICS IN PEPYS'S DIARY.

At the social evening of the Royal Society of Medicine on February 15th, when Sir James and Lady Berry received a large company of Fellows and guests, Colonel W. P. MacArthur, just returned from Shanghai, gave a very interesting lecture on the medical references in Samuel Pepys's diary. It was remarkable also as a feat of memory, for, without the use of a single note, the lecturer had every name, date, quotation, and reference at his finger-tips. He reminded his audience that the diary began in 1660 and covered a period of nearly ten years. The medical references are numerous, and, unless our memory is at fault, Sir D'Arcy Power once wrote a charming paper on the medical history of Mrs. Pepys. Colonel MacArthur recalled the diarist's account of a successful experiment in blood transfusion, which "may be of mighty use to man's health, for the mending of bad blood by borrowing from a better body." Pepys had some reflections also on his own operation for stone. A stone larger than a tennis ball, according to Evelyn, was removed, and this pathological relic Pepys carried about in his pocket to show his friends. The mid-seventeenth century saw fearful ravages from small-pox, and Pepys told the story of the tragic disfigurement of Frances Theresa Stuart, a court beauty, said to have been the original of Britannia on the coinage. In March, 1668, the unfortunate lady is "mighty full of the small-pox," which, Pepys added sententiously, "is the greatest instance of the uncertainty of beauty which could be in this age." A very heavy toll was taken by small-pox at this time, and it did not spare the royal family. Colonel MacArthur appeared to think it was small-pox which caused the death of the young Duke of Gloucester in 1700, and so cleared the way for the Elector of Hanover, George I, to the English throne, but the *Dictionary of National Biography* says otherwise. In the Tudor period Colonel MacArthur failed to trace any similar record of small-pox virulence. At that time it was bracketed with measles and accounted a childish affection. It was interesting to speculate whether the mild type of small-pox now prevailing would again be mentioned in the diary in the summer of 1661, and was attributed by Pepys to the extraordinarily warm weather, which persisted through the autumn and into the winter.

This strange fever was not plague, small-pox, or typhus, with all of which Pepys was too familiar, but it could be gathered from the pages of Sydenham to have been malaria, or, as Sydenham called it, intermittent fever. The most extensive of Pepys's medical interests was concerned with the London plague of 1665. This was an epidemic of bubonic plague affecting the chief residential district of London—the City—which was at that time filthy and congested. It was the last of a long series of epidemics which had flared up at intervals; the seventeenth century had already seen three great outbreaks. Pepys's earliest mention of the epidemic was in April and May, when he noted the great fear and dread in the City, several houses being shut up and marked with the plague sign. In his own parish there were as many burials in four weeks as there had been in the whole year before. Entire families were wiped out. The bills of mortality, to which Pepys made frequent reference, were originally concerned with plague deaths only; but from 1592 they were issued weekly by the London Company of Parish Clerks, and gave the deaths from all causes. Four principal outward manifestations of the plague were noticed—namely, the botch or bubo, the carbuncle, the token, and the blain; of these only the first is now commonly found in association with plague. A letter by Pepys showed that the diarist stayed on in London until the recorded deaths reached 6,000 in a week, and the nights, although lengthening, were too short to conceal the burials. His household returned to London in December. Plague persisted in London for another fourteen years, but with the enforcement of cleansing orders and a higher standard of sanitation there was no further epidemic. In conclusion, Colonel MacArthur said that those who had estimated Pepys's character from the more frivolous pages of his journal might do well to recall that he was an indefatigable and conscientious worker, a most efficient public servant, and an honest man according to the ideas of his time. He received many honours, he was President of the Royal Society, Master of Trinity House, Warden of the Cinque Ports, member of Parliament, friend and correspondent of Isaac Newton, John Evelyn, and Hans Sloan. But he had a claim to the goodwill of the medical profession because he held the science of medicine in high regard—a regard by no means universal in old times, as witness a passage from a book almost as intimate and revealing as the diary, namely, the Paston Letters. In a letter written by Margaret Paston to her husband in 1464 occurred this distressing passage: "Also for Goddys sake be war what medesyns ye take of any fysissians in London; I schal never trust to hem be cause of your fadr and myn onkyl, whoys sowlys God assoyle."

#### DUTCH AND DANISH CONDENSED MILK.

In August last year the Minister of Health dispatched a commission to the Netherlands and Denmark for the purpose of inquiring into the conditions of production of the milk used in preparing condensed brands. This visit followed an earlier one to the two countries paid by delegates from the city of Liverpool; we gave a short account of the report of this deputation on April 2nd, 1927 (p. 635). The present commission consisted of Dr. J. M. Hamill, a medical officer of the Ministry of Health, together with Mr. T. A. Hole, a milk inspector, and Mr. J. Mackintosh, professor of dairy husbandry at the University of Reading. The report of Dr. Hamill and his colleagues has just been issued. It is satisfactory to note that neither in Holland nor in Denmark did the observers find the conditions of milk production markedly superior to those existing in England. In Holland cows are milked in the fields instead of sheds for six months in the year. Any disadvantages in the cleansing of utensils are neutralized by the rapidity with which the milk is removed to the condensery or

creamery. The floor construction in the cowsheds is generally superior to English construction. This is due to the sheds having been built for the specific purpose of housing cows, instead of being intended originally for some other purpose. The commission was struck by the similarity in principle of Dutch Government regulations and our own for controlling the purity and cleanliness of milk. Administration works smoothly. The Dutch authorities have not yet adopted official veterinary inspection, but the matter is now under consideration. Private organization for controlling the purity of milk and the health of the cows is good, and in the co-operative societies has attained considerable efficiency. Conditions in Denmark are similar to those in Holland, but the cowsheds are said to be even superior to the average Dutch type. Government regulations for the control of purity and cleanliness of milk resemble those of our Milk and Dairies Order for milk intended to be consumed as such. But milk intended for conversion into condensed milk is exempt from these regulations, though others of a less specific and detailed character are now in contemplation. The commission concludes that neither in Holland nor in Denmark are the conditions of production, the regulations, or the administration sufficiently different to warrant any differentiation, on the grounds of danger to health, between dairy produce in England and that in the two countries visited. Nor is it thought that English regulations place any significant burden upon the English farmer which is not already borne by the farmers of Holland. Otherwise the main interest of the report for the British farmer should be the evidence it offers of the successful results of co-operation in the production, transport, and distribution of milk, and in the manufacture of milk products in the two countries investigated. These points were emphasized also in the report of the Liverpool deputation.

#### THE EVILS OF TOBACCO.

PROHIBITION, like drug-taking, whets the appetite for further indulgence. It appears that in America there are many people who regard tobacco as the next subject for legislative attention. To inform the public on the matter there exists a Committee to Study the Tobacco Problem, which includes in its membership not only Mr. Henry Ford, a chief executive of the boy scouts, and a professor of theological exegesis, but also numerous medical and physiological professors at universities. The committee has recently issued a book by Dr. Pierre Schruppf-Pierron, professor of clinical medicine in the University of Cairo, entitled *Tobacco and Physical Efficiency*.<sup>1</sup> The president of the committee, Dr. Alexander Lambert, in a foreword, claims that the object aimed at is an unbiased presentation of every variety of opinion. Professor Vaguez of Paris has written a preface, and explains why he advises the total abandonment of tobacco in patients with cardiovascular lesions, manifest or latent. At the end of the book there is a very complete bibliography of the literature of tobacco. As regards Professor Schruppf-Pierron's contribution, we can only say that it is not very illuminating. He states that tobacco may cause headache, migraine, vertigo (how true of the first pipe!), insomnia, and amnesia; but in many conditions of a graver nature that are mentioned it might be better to say merely that sufferers from such disorders sometimes smoke tobacco. It is satisfactory, however, to learn that the charge that tobacco causes actual lesion of the heart is "not proven," and that in women smoking itself has no apparent influence on the functions of the genital system. The author is of opinion that further controlled clinical and laboratory

studies are desirable to ascertain the ultimate effect of prolonged moderate use of tobacco, as well as of its free use. He wisely adds that the dangers of excessive indulgence in tobacco should not be exaggerated, and that tobacco should not be placed on the same plane as morphine and cocaine. Recollections of nonagenarians enjoying their pots of beer and pipes of shag lead us to endorse this view. Our readers will remember that on October 22nd, 1927 (p. 719), we published Professor W. E. Dixon's Norman Kerr Lecture on the tobacco habit. The very reasonable conclusions at which Professor Dixon arrived included a plea for further investigations, especially into the question how far the use of tobacco leads to vascular degeneration. Professor Schruppf-Pierron's book confirms our opinion that the effects of this very slow poison are not yet ripe for dogmatic statement.

#### THE UNITED HOSPITALS CLUB OF ST. THOMAS'S AND GUY'S.

THIS ancient club held its centenary dinner on February 16th last. It was founded on February 15th, 1828, by two general practitioners—then called apothecaries—educated at the Borough hospitals, St. Thomas's and Guy's. Its object was to maintain and keep alive the friendship that had always existed between the two great institutions, lest this should be imperilled by the opening of the independent school at Guy's in 1826. The United Hospitals Club is proud to remember that its foundation was owing to the general practitioner; for at the foundation meeting, held at the London Coffee House, twenty apothecaries were present and only two members of the staff of the hospitals. The club consists of eight of the staff from each hospital and nine general practitioners, who by dining together four times a year renew the dual friendship. The club entertains guests, and during the hundred years of its existence has welcomed most of the prominent members of the profession both from home and abroad. It was not until 1836 that the complete separation of the two schools took place, in consequence of a disagreement as to the attendance of the students of each hospital on the practice of the other, whilst the removal of St. Thomas's to Lambeth sixty years ago further emphasized the separation. More than ever then did the club appreciate its usefulness; not that now it is needed to increase the friendship between St. Thomas's and Guy's—that is impossible—but rather as a concrete and permanent reminder of past relationship and an earnest of future good feeling. At its centenary dinner, under the joint chairmanship of two of its oldest members—Sir George Makins (St. Thomas's) and Mr. C. H. Golding-Bird (Guy's)—it broke one of its most rigid rules, which permits only members of the profession as guests. It entertained last week the treasurers of the two hospitals, Sir Arthur Stanley and Mr. F. P. Whitbread, thus clinching the union, in public, of two famous medical institutions now removed a distance from one another. Perhaps Guy's Hospital reaps the greater advantage from the club, for its founder, Thomas Guy, was a governor of St. Thomas's. In this filial relationship Guy's may claim to have a full share in the traditions of St. Thomas's, extending back over six centuries, of which, indeed, St. Thomas's has good cause to be proud.

At the meeting of the President and Council of the Royal Society on February 16th it was decided to recommend fifteen candidates for election as Fellows. Among those chosen are two members of the medical profession: Dr. Carl Hamilton Browning, professor of bacteriology in the University of Glasgow, and Dr. Major Greenwood, professor of epidemiology and vital statistics in the University of London.

<sup>1</sup> *Tobacco and Physical Efficiency*. By Pierre Schruppf-Pierron, M.D. Preface by Henri Vaguez, M.D. With a foreword by Alexander Lambert, M.D. New York: E. B. Hoeber, Inc. 1927. (5½ x 8½, pp. xiii + 134. 1.85 dollars net.)

## "THOSE OTHER PRACTITIONERS."

AN ADDRESS TO THE

ABERNETHIAN SOCIETY OF ST. BARTHOLOMEW'S HOSPITAL,  
JANUARY 26TH, 1928,

BY

LORD DAWSON OF PENN.

My intention is to refer to those practitioners who do not give allegiance to the medical profession and are styled unqualified. That such should have existed in past centuries does not cause us surprise, but that their activities show little sign of abatement in this age of scientific inquiry should prompt us to reflection. No doubt the desire for gain and notoriety is a partial, and in some instances a complete, explanation of their activities, but many of them, however mistaken, have an honest belief in themselves and their work.

### *The Unqualified Practitioner.*

A quack may be described as a man who makes baseless and boastful pretensions for a method of treatment. He may be one who deceives himself before deceiving other people, or one who deceives other people without deceiving himself. It has to be admitted that the quack may exist inside as well as outside the ranks of the profession. For my present purpose I exclude from this purview those who have the intention to be impostors and whose methods are designedly dishonest. The unqualified or irregular practitioner need not be a quack. In some instances his methods of treatment are helpful, provided they are applied under the right conditions.

To keep the art of medicine firmly set on the rock of knowledge and defend it against false doctrine what vantage ground should we select? I suggest to you that we should take our stand on diagnosis. Here our position is unassailable. To attempt to treat disease without knowing what is wrong would be folly. Diagnosis must precede treatment, and the knowledge of diagnosis can only come from years of training in the sciences of physics, chemistry, biology, anatomy, physiology, pathology, bacteriology, and then in the study of the bodies and minds of the sick at the bedside. Educational authority must, in the public interest, see that such training is adequate.

However much public opinion might be carried away by this or that cult or miraculous cure and demand of us to take its exponents into our confidence, it never would give these independent practitioners the rights and duties of medical men, any more than it would permit a heaven-born though untrained engineer to drive a train or an Atlantic liner.

Diagnosis, then, is our sure ground; it is a clearly defined and exclusive province of medicine and the sciences on which the latter is based. On the other hand, treatment is not the apanage of doctors alone. The art of healing has in all ages been the concern of peoples and has been blended with their desire to help and save. Its instinctive promptings exist in each individual—man and beast; witness the dog who licks the inflamed paw or seeks out a special variety of grass. The apothecary or "village dame" of former ages gathered from the countryside the herbs and simples from which potions, having reputo amongst the people, were made. The herbalist would gather the wood anemone with the ceremonial ordination "I gather thee as a remedy against all disease." Similar ceremony attached to rosemary, and the Druids called mistletoe "All heal." Nor did surgery escape the influence of popular belief.

If we survey the field of treatment to-day we find it on the one hand adjacent to such defined and ordered territories as anatomy, physiology, chemistry, and pharmacology, and in other directions merging into the less defined regions of mind, feeling, faith, belief, even superstition, all of which penetrate far back into time and human history. That medicine should have as one of its styles and titles "The art of healing" reminds us that for the public a main purpose of our existence is to make suffering people

well. Thus it is that unqualified practitioners centre their activities in the treatment of illness. From the innumerable cults and cures, past and present, I will select a few examples.

### *Perkins and Mesmer.*

Elisha Perkins (1740-99) was in the earlier part of his career a country practitioner. Later he invented the "metallic tractors," which consisted of two rods of metal—one of gold, copper, and zinc, the other of iron, silver, and platinum. These rods were drawn over the affected part, and acted by the electricity they were alleged to produce. They cured most things—pain, rheumatism, tumours, boils, pleurisy, and various nervous diseases. The vogue was great—all sorts and conditions of men, including noblemen, statesmen, and divines, supported his claims; real cures resulted, though how permanent they were is doubtful. Then came decline. Finally Dr. Haygarth of Bath showed that tractors of wood painted like the metal ones produced even greater cures, and so the bubble burst.

Mesmer (1734-1815), who took his M.D. at Vienna in 1766, based his cures on the use of magnetism. In Vienna he was not accepted, but, moving to Paris, his reputation grew and he became the rage. At first he was only misguided. When his influence grew vanity obscured his honesty, and one reads of all the paraphernalia of the charlatan—spacious salons, stained-glass windows, coloured lights, fragrant fumes, velvet, and soft music. Let me quote:

"In the middle of the principal salon was deposited an oval vessel, about four feet in its major diameter and one foot in depth. This receptacle contained a number of wine bottles, filled with magnetized water, well corked, and disposed in order, with their necks outwards. The vessel was filled almost to the brim, and iron filings were thrown into it at intervals, to increase, it was said, the magnetic effect. An iron cover, called the *baquet*, perforated with many holes, completed the apparatus—a long movable rod of iron issuing from each aperture for the patients to apply to the diseased parts of their bodies. The patients sat round the vessel, holding each other's hands, and pressing their knees together as closely as possible, in order to facilitate the circuit of the magnetic fluid.

"The assistant magnetizers then entered—stalwart and handsome young men, who were supposed to pour into the patients from their finger-tips a fresh supply of the magnetic fluid. They embraced the patients between the knees, rubbed them gently down the spine and along the course of the nerves, pressed gently on the bosoms of the females, while fixing them with a magnetic glance from their eyes—in anticipation of the Ancient Mariner and the Wedding Guest in Coleridge's ballad."

It is difficult to believe how Mesmer took possession of public attention. His methods attracted the Court and the Government. The latter offered a pension of 20,000 francs and a decoration if he would communicate his discovery to physicians nominated by the King. This offer he evaded. Later commissioners investigated his pretensions and reported against them, and finally he became discredited.

### *Osteopathy.*

The osteopath is the descendant of the bone-setter, and it is an interesting fact that Barker succeeded to the practice of Hutton, who was a well-known bone-setter of the Victorian era. Osteopathy ascribes maladies to misplacements of anatomical parts, and especially to faulty arrangements and alignment of the vertebrae. The treatment consists of manipulation of the misplaced parts with a view to their correct replacement. It is done with vigour and often accompanied by clicks, which provoke a strong and confident statement that the malady will immediately cease, and so sometimes it does. I have not heard of skiagrams being taken before and after the treatment. One may discern in these treatments (a) physical examination and treatment of the body, and (b) influence on the patient's mind. Sometimes there is a dexterous manipulation of the part affected, and in other instances there is only a ritual handling of the body, and this is made the means of exerting forcible impressions on the mind.

There is nothing radically unsound in these methods. When they fail it is because a false diagnosis of the condition has been made. If the manipulation is harmless there may remain a beneficial effect due to suggestion. Where the case is one unsuitable for manipulation grave harm may result.

There are gifts of hands often inborn—not acquired—a dexterity without a reasoned basis, and therefore not teachable to others. Such is so-called manipulative surgery. If it were practised within its proper ambit, if it were only applied after skilled diagnosis had been made and skilled direction given, how useful it would be! I come back to what must ever be our undeviating insistence—diagnosis must precede treatment.

#### *Faith-healing.*

I now pass to the consideration of methods of treatment which depend on mental influences and use but little manipulation or other physical modes of approach. I will select Coué's teaching, and what may be conveniently comprised under the term "faith-healing."

M. Coué's method seeks to take control of the patient's subconscious mind: the constant and rhythmical repetition of the phrase "*Ça passe*" for the time so occupies the subconscious mind that the latter is impervious to the influence of reason. With periodic repetition of this exercise the impression remains, and the subconscious mind accepts and keeps the idea that this or that symptom has passed.

The merit of M. Coué's method is that it trains the patient to help himself. But is that all? No; M. Coué's forceful, cheerful personality, his atmosphere of sincerity and confidence, made a deep impression on his patients; he immediately secured followers who passed into disciples; and the fact that he impressed on his hearers that his personality counted but little deepened his influence, for is it not true that mental influences often reach their best when they are incidental rather than intentional, implicit rather than explicit? The Coué method is, in short, auto-suggestion reinforced by suggestion.

So far, so good. The method, applied to functional disorders, whether standing alone or as part of organic disease, is one of usefulness, and only disadvantageous because of its detachment from other treatment and when its claims go beyond facts. But when its claims are extended to the curing of developed structural disease then a doctrine is being propounded which is not only erroneous, but dangerous; and a similar false doctrine is found in the teaching of Christian Science and some forms of faith-healing. There is no evidence, for example, that a tumour disappears under psychical treatment, and such teaching is dangerous because it leads patients to postpone physical treatment until too late. "Render unto Caesar the things which are Caesar's, and unto God the things that are God's."

Faith-healing is so large and diffuse a topic that I will limit myself to healing by the influence of a personality. Here the healing depends on the attributes of the personality and the reaction of the patient. The attributes of the healer are in part inborn, though cultivation may do much to enhance them; whether they can be inspired from without—that is, implanted by Divine gift—is a question outside our present inquiry.

Our daily experience leads us to conclude that the influence of mind is an integral part of the art of healing. Let me give you two examples. A patient, after weeks of unconsciousness due to typhoid fever, gradually emerges and for a fortnight remains on the threshold of consciousness. We all know how painful and enfeebling that phase can be—dreams, terrors, eries, restlessness, insomnia—and narcotics and hypnotics gave but poor results. Then, by good fortune, comes on the scene one nurse who, by touch and voice—or shall I say through touch and voice?—quells the troubled spirit, gives sleep, and contributes in no small measure to recovery.

Another example. An aged lady, great in mind and character, had recurrent carcinoma of the breast and suffered agonies of pain in her arm. One day she said "Would you mind if we let a healer try and help my arm?" and she mentioned the best-known healer of that time. I assented, and offered to meet the healer in consultation. For several weeks that healer substantially reduced the pain and brought her peace. One day she said to me, "I feel the good Mr. X can do me is over, and I would like his visits to cease." By that time the end was nearer and morphine carried us through.

In both these instances we saw mind healing at its

best. Why? Because it was not dissociated from physical healing. When dissociated, mind healing loses its sense of proportion, its pretensions grow and grow, the healer falls with dangerous facility into a dependence on the accidentals rather than the essentials of his art. He thus gets on to a basis of falsity rather than truth, and he becomes as sounding brass and tinkling cymbals. There is no department of treatment which goes mad so easily as psychotherapy.

The remedy for these dangers is to secure that all forms of treatment should be guided and co-ordinated by the doctor; but this supposes a wide comprehension on the part of the medical profession of what treatment includes and a readiness to secure the help of ancillary callings. Such comprehension is growing apace. I need only instance the midwife, the masseur, the electrician; and why not the manipulator and healer, provided always one essential—that diagnosis and direction precede treatment?

#### *Mind and Body.*

As regards mind treatment, there is danger of it losing direction in the learning of medicine; on the one hand advances in pharmacology rightly give prominence to specific remedies like digitalis, insulin, emetine, quinidine, etc., and on the other hand there is a tendency to push the estimate and treatment of the mind factor into the ken and care of the psychotherapist. Therein lies error: body and mind cannot be thus separated either in diagnosis or treatment. In both functional and organic diseases there are the reactions of mind and temperament, and we have to study not only the material disease, but the complete fabric or make-up of this or that personal illness.

Moreover, structural disease may have a psychical as well as a physical beginning. Let me instance Graves's disease and certain forms of high blood pressure. Inborn traits and reactions—impressionability, sensitiveness, over-conscientiousness—reacting on some varieties of physical make-up will produce, say, increased secretion or vaso-constriction. Then develops what may be called physiological habit, and so gradually there evolves full-fledged structural disease.

Thus is emphasized the importance of the study of medicine by the student at the bedside. There he will study first the symptoms and signs of physical disease, and at the same time will be brought in contact with characters, temperaments, and difficulties of patients' lives which go far to determine the form of their illnesses. In this way imaginative insight will gradually become one of the qualities of the student's mind.

The psychical factor in illness is likely to play a larger, not a smaller, part in the future; the material resources of civilization have developed so rapidly that they have outstripped man's power of adaptation, and strains and conflicts will need more careful consideration. That is seen in the increase of illnesses due to "exhaustion" states, which illustrate that the best healing of the mind is that which is not obtrusive and still less exclusive, but rather accompanies a sound physical treatment. Absence of the latter and the ascribing of the illness to "neurasthenia" or erroneous habits of thought are apt to delude the patient. Even if true, the "sick" are not yet prepared for this; they cannot get away from the feeling that what is physical is real and something they cannot help; whereas what is psychical is unreal and something they can help. This misconception is perhaps due to mistaken teaching about the doctrine of freewill.

From this I am led to suggest that psycho-analysis should be limited to selected cases, and its practice to the few who are specially trained and possess the needful gifts of mind. Psycho-analysis requires the clinician; it should never be crude and lay bare a patient's soul. Clumsy questioning, like clumsy surgery, can easily produce irreparable damage.

I plead, therefore, that we should take a large and comprehensive view of treatment: that physical and psychical healing—or, as it will some day be, physical and psychical education—should not be divorced from each other, and that all forms of treatment should be co-ordinated and directed, though not necessarily executed, by the doctor and based on sound and accurate diagnosis.

## Scotland.

### Proposed Compulsory Treatment of Venereal Diseases in Edinburgh.

THE Edinburgh Corporation is at present promoting a parliamentary bill<sup>1</sup> for compulsory treatment of venereal diseases, and the medical officers of Parliament and the medical officers on the subject. The corporation holds that at present the scheme for treating these diseases is not yielding results commensurate with the expenditure involved, and that the purely voluntary system, having received an adequate and exhaustive trial, has proved ineffective for the purpose of preventing infection. They therefore desire to try the methods they propose for an experimental period of five years. According to a statement which has been issued over the signatures of Councillor Given (convener of the Public Health Committee), Mr. Andrew Grierson (town clerk), and Dr. W. Robertson (medical officer of health for Edinburgh) the publication of the report of the Royal Commission in 1916 led to extensive propaganda for the object of public enlightenment on the grave evils of these diseases and to the establishment of facilities for their treatment free of cost, with, so far as the patient was concerned, as little publicity as possible. As a result, it is stated, local authorities were brought into touch with a large amount of this disease, and many of the patients treated had been cured. Under the Edinburgh Corporation venereal diseases scheme a total of 19,059 new patients had reported for treatment during the five years 1921 to 1925. During the period, however, a very considerable number of these patients had ceased attendance long before they were considered cured. During 1925-26, for example, there had been 903 such defaulters, while the total number of defaulters during the five-year period was 5,129. It is considered that the fact of there being in each year an average of over 1,000 cases of possible infective disease known to the public health authority, while this authority is powerless to deal with them, is far from satisfactory when viewed from the public health aspect of preventable disease. This also leads to the local authority expending very considerable sums of money without an adequate return. The expenditure in connexion with the Edinburgh scheme in the past year was £21,862, of which £11,125 was recovered in the form of Government grants. The operative clause of the bill now to be submitted to Parliament provides that when the medical officer of health has reason to believe that any person is suffering from venereal disease and liable to infect other persons, and when such person neglects or refuses to undergo treatment by a medical practitioner or at a treatment centre established by the corporation, the medical officer of health may notify him to consult a medical practitioner or attend a treatment centre. Failure to carry out such a requisition and the giving falsely, without reasonable cause, of information that a person is suffering from venereal disease are to be punishable by fine. The executive committee of the Edinburgh and Leith Division of the British Medical Association, at a meeting held on February 18th, discussed the proposals of the Edinburgh Corporation, and passed a resolution in support of them. The matter will come before the Division on February 28th. The bill was discussed this week by the Parliamentary Medical Committee, together with representatives of Edinburgh Corporation (see p. 330).

### Glasgow Victoria Infirmary: Admission of Paying Patients.

The fortieth annual meeting of the Victoria Infirmary of Glasgow was held on February 15th. The annual report of the Institution was noticed in the JOURNAL of February 11th (p. 235). Mr. William Gray, chairman of the governors, made an important statement at the meeting in regard to the admission of patients for treatment on payment of an inclusive modified fee. He said that the governors had been impressed by the strong recommendation of the Hospital Services Committee, which had been appointed by the Government to inquire into the work done by the voluntary hospitals in Scotland. Most of the

witnesses before this committee had urged the need for hospital facilities for persons of moderate means who could not afford the charges of the ordinary nursing homes. The practice of providing beds for paying patients was now spreading, and the question of extending it to the whole hospital system was one of the definite issues before voluntary hospitals. After careful examination a suitable scheme had been formulated by the governors of the Victoria Infirmary, and this would be put into operation as soon as the necessary accommodation was available. It was proposed to admit patients on payment of an inclusive fee of six guineas per week, which would be sufficient to cover maintenance and nursing charges as well as a modified fee to the surgeon performing the operation. The speaker expressed indebtedness to the surgical staff of the institution, who had agreed to carry out the work at a scale of fees much below the ordinary charges. The scheme would, however, not interfere with the patients for whom the voluntary hospital was intended, and the present accommodation would not be used for fee-paying patients, for whom an annexe to the existing hospital would be built, with access to the present operating theatre. He felt convinced that the decision of the governors to extend the field of the Victoria Infirmary in this direction would be welcomed by a large section of the citizens, who could feel that there was some prospect of treatment being carried out under the most favourable conditions, at a cost which it would be within their ability to pay without undue anxiety.

### Glasgow Royal Asylum.

The annual meeting of the Glasgow Royal Asylum was held on February 16th, with Professor Glaister in the chair. Dr. D. K. Henderson, medical superintendent, in his report said that there had been 518 patients in the asylum at the close of the year, while the total number under treatment during the year had been 671, and the average daily number resident 527. There had been 138 admissions and 153 discharges, with 59 deaths. All the patients admitted were private cases, and of these 76, or over 60 per cent., had been voluntary patients. Attention was drawn to the fact that this was a record for this mental hospital, and was an indication of the growing tendency in regard to mental hospitals generally. The voluntary patient made the best and quickest recovery as a rule; indeed, the great majority of patients who got well from mental diseases did so within the first year after admission. Thus of the 51 recoveries 47 took place during the first twelve months of residence, and of these the great majority had recovered within three months after admission. The chairman, in moving the adoption of the report, said that many people were going about to-day whose mental balance was a very precarious affair, but who could not be certified as insane, although they were deficient in the power of adapting themselves to their social environment, and so did not conform to necessary requirements. At the present time many sexual crimes were committed by these people, and he was convinced that the only remedial treatment of value to them would be confinement in a place of custody.

### Royal Medical Society of Edinburgh.

The annual dinner of the Royal Medical Society of Edinburgh was held in the Royal College of Surgeons on February 16th. Dr. W. Mitchell Innes, senior president of the society, presided, and the guest of the evening was Dr. A. Logan Turner. In proposing the toast of the Royal Medical Society Dr. Logan Turner remarked that Charles Darwin, when he was a student in Edinburgh, attended the meetings of the society regularly, and spoke of it in his autobiography. Many of the students who were now members would in future belong to other societies, but they would always look back with pleasant memories to the days they had spent in this society. The society for a time had gone down, but since the war it had enjoyed increasing prosperity, which its friends trusted might long continue. One of its earliest activities had been the founding of a library, which had steadily grown until there had now risen the important question of the accommodation and proper arrangement of its books, and he hoped that this matter would be settled satisfactorily.

<sup>1</sup> The essential clause of this bill will be found in the SUPPLEMENT this week at page 66.

Dr. J. A. Bruce, one of the society's presidents, in replying, said that in the present year the membership had showed an increase of 60, which was a record for the society. Dr. L. B. Wevill, proposing the toast of the Edinburgh Medical School, said that the greatest feature of the school had been its success in turning out good general practitioners. A medical school must ultimately stand or fall by the average of men which it turned out, and Edinburgh in the past had produced practitioners of great intellectual honesty, of keen observation, and possessed of a capacity to draw logical conclusions from the facts which they observed. On this type of man the greatness of the Edinburgh Medical School had been based.

Attention may be drawn here to the fact that an appeal has recently been issued by the officers of this society in order to raise an endowment fund of £3,000 for the purpose of ensuring the proper preservation of the library and rooms and of obtaining the services of a full-time librarian. The scheme is intended to celebrate the bicentenary of the society, which will fall in 1937, and it is launched at this early date in order to give members an opportunity of paying ten annual contributions—if they prefer to do so—instead of giving a lump sum. Old members who desire to subscribe to this object should send subscriptions to the treasurer, Royal Medical Society, 7, Melbourne Place, Edinburgh.

## Ireland.

### Medical Services in the Free State.

THE Minister for Local Government and Public Health, accompanied by the Secretary of the Department, Mr. T. MacArdghail, and Dr. Stephenson, lately received a deputation representing the Irish Medical Committee. The deputation consisted of Drs. A. McBride, J. F. O'Connor, O'Brien (Wexford), McCann, Conor Maguire, Armstrong, and J. P. Shanley, with Dr. T. Hennessy (Irish Medical Secretary), and Mr. C. H. Gick (Secretary, Irish Medical Association). The questions raised related to the dispensary medical service, to county hospitals, to the public health service, and to miscellaneous matters. The deputation pointed out the inadequate salaries paid to dispensary medical officers, particularly in Mayo and Longford, and asked the Minister to regulate the salaries in these counties on the basis of the scales sanctioned in other counties. The Minister, while fully sympathizing with the medical officers, stated that he was not at present prepared to issue sealed orders determining the salaries in these counties. He promised to explore the situation fully so as to ascertain the most desirable way of dealing with it. Dr. Hennessy drew attention to the transfer of medical officers by local authorities, and urged that transfer should be regarded as promotion, not as patronage, and that seniority and meritorious service, and post-graduate qualifications and experience, should be the determining factors. He considered that such transfers, in the first instance, might be restricted to the county areas. It was suggested that the local authority seeking to transfer an officer should state in the first place if it intended to limit the selection to the county. Attention was drawn to certain cases in which local authorities had not accepted the locumtenents nominated by the medical officers during holiday and sick leave. The policy of the department to afford all reasonable facilities to dispensary medical officers to enable them to avail themselves of their holiday leave, and the legal aspect of the question, were explained. During the discussion of questions relating to county hospitals the deputation stated that the salaries of county surgeons were inadequate, and a scale of £800 to £1,200 was suggested. No decision was come to, but the Minister stated that individual cases would be examined as occasion arose. The deputation was opposed to an inclusive salary for county hospital surgeons in any circumstances. The relationship of the county surgeon and the matron in regard to the control of county hospitals was considered, and a few alterations in the general regulations were suggested to strengthen the authority of the medical officer. Dr. O'Connor undertook to submit amended regulations raising the points at issue.

The department in this matter would raise no objection if its general policy was not transgressed—that is, the matron to be primarily responsible for administration and the medical officer for treatment. The members of the deputation expressed general acquiescence with the draft regulations relating to private wards for private patients issued by the department, and urged that these regulations should be applied to all county hospitals. It was stated by members of the deputation that persons who were able to pay the full cost of maintenance and treatment and medical fees were being treated in the Poor Law wards of county hospitals, and the hospitals were being freely utilized by persons not eligible for relief. Longford was mentioned as the outstanding example of both forms of these abuses. A thorough examination of the records of this and other hospitals was promised by the Minister. As regards the delay in appointing county medical officers of health in certain counties, the Minister said that the matter was not being overlooked, and would be pressed as opportunity offered. As regards medical research the Minister said that he had had the question under consideration for some time, and if a suitable scheme was submitted by a committee representative of the medical schools he would make representations to the Department of Finance for a grant. The consideration of other questions, relating to registration fees for births, deaths, and marriages, and fees for the committal of dangerous lunatics, was deferred, as the discussion of the previous matters had occupied over two hours.

## England and Wales.

### Small-pox in London.

THE number of cases of small-pox under treatment in Lambdon on Tuesday, February 21st, was 19, an increase of 3 since February 17th. All these cases are being treated at the Long Reach Hospital of the Metropolitan Asylums Board. In addition 8 cases of possible infection were under observation at the Board's diagnosis station at Rotherhithe, as against 7 in the previous week; 3 of these 8 cases, however, were on the point of being discharged from observation, and of the remaining 5 it was reported that 4 had not shown as yet any signs of small-pox. The procedure is for suspected cases to go first to this Rotherhithe station, where they are seen by the medical superintendent of the small-pox service, who decides whether they should go on to Long Reach (to which they are transported by river ambulance), or be returned home as free from the disease, or, if their condition is doubtful, be kept for further observation. The majority of the cases at Long Reach and of the recent suspected cases are from the Southwark area, and of these nearly all are related to the outbreak at the Poor Law institution of the Southwark guardians. All the cases reported are of a mild type, with no special features; they approximate in this respect to the majority of the cases recorded elsewhere in the country, but they differ from the small-pox cases in London of recent years, which, though few in number, have been more often virulent in character.

### Royal Bath Hospital, Harrogate.

Financial considerations were prominent at the annual general meeting of the Royal Bath Hospital, Harrogate, on February 15th. The secretary, in his annual statement, reported that the number of patients in 1927 was considerably in excess of any previously recorded since the policy had been adopted of keeping the hospital open through the winter months. During the past year accommodation for electrical treatment and remedial exercises had been much improved. The honorary treasurer stated that of the £12,000 asked for in connexion with the centenary fund, less than £8,000 had been received. So far as the hospital itself was concerned a financial profit had resulted on the year's working, but the Rawson Convalescent Home showed a deficit of £189. To complete the work contemplated in connexion with the centenary some £2,000 to £3,000 was still required, and for the moment the very necessary improvements proposed were at a standstill. Dr.

G. L. Kerr-Pringlo, replying to a voto of thanks to the medical staff, referred to current exaggeration of the cost of treatment at Harrogate, and mentioned that the average was said to be about 26s. a week. During the four winter months December to March there was accommodation in the hospital for those who could not afford the charges at the Royal Baths, with residence in the town, and who were able to pay three guineas a fortnight; many patients were already being admitted each year, and the number was increasing. He hoped that a proportion of the charges made might soon be placed to the credit of a medical fund for research into rheumatic diseases. Most of the patients treated in the hospital were suffering from the rheumatic group of diseases, and the institution, already constituted a rheumatic clinic. At present the laboratory cost the hospital £350 annually, towards which only a small endowment of about £50 was available. Dr. Kerr-Pringlo urged that more extensive propaganda should be adopted, since many patients came from large manufacturing towns from the West Riding which did not contribute towards the support of the hospital as they might. He thought the time had come for the launching of a crusade in Yorkshire against rheumatism; Harrogate, owing to its site and its well-equipped hospital, might well be the centre of an intensive campaign against this disease.

#### Temporary School Medical Staff's Remuneration.

The London County Council at its meeting on February 14th decided to increase the rate of pay of its temporary school medical staff. The staff is divided into two classes, those employed on a sessional (that is, a half-day) basis and those appointed on a part-time yearly engagement. The revised pay for the first class will be 30s. a session, instead of 27s. 6d. as hitherto, and for the second class £198 a year for duty consisting of three half-day sessions a week, instead of £180. The first of these classes has at present a personnel of 22, fluctuating according to the needs of the work. The second has a personnel of 53, of whom 13 serve for six sessions a week (so that their remuneration will now be £396 a year), and 40 for three sessions a week. All the existing engagements of these officers (with the exception of one who has resigned, and in whose place another has been appointed) have been renewed for a further period of one year.

## Correspondence.

### GASTRIC SECRETION OF NEUTRAL CHLORIDE.

SIR,—Stimulated by your review of the annual report of the Medical Research Council I turned to the report itself, and there, in the summary of the work done at St. Thomas's Hospital on gastric physiology and pathology by Professor Maclean and his colleagues, I find this striking passage:

"The gradual decrease of acid concentration in the stomach during the completion of digestion is shown to be a function of the stomach itself, and in no way to be dependent on regurgitation of alkaline duodenal contents. The increase in neutral chlorides which coincides with a diminution in active hydrochloric acid is due to the neutral chloride actually secreted by the stomach itself. This has been conclusively proved by experimental work with dogs combined with clinical observations."

I first heard rumours that Professor Maclean had been led to this conclusion about a year ago, and since then it has been known and accepted apparently by quite a number of people. Now that we have this *ex cathedra* pronouncement of conclusive proof, may I express the hope that before very long we may be given what some of us have been anxiously waiting for—to wit, the evidence? Speaking for myself, I find it a very disturbing thought that in talking of the importance of the regurgitation of the duodenal contents I am daily teaching an erroneous doctrine; but if I am to be true to the faith that is in me I am bound to do this, until Professor Maclean tells me not only that I am in error, but also where my error lies. If in my present state of ignorance and impatience for the truth I may be permitted one mild criticism,

I would add that I am not particularly attracted by this reversal of the older custom of giving the evidence first and the conclusion last.—I am, etc.,

London, W., Feb. 15th.

GORDON W. GOODHART.

### THE NEW PORTRAIT OF JOHN HUNTER.

SIR,—I knew nothing of Sir Arthur Keith's discourse on the portraits of John Hunter until I read it in the *BRITISH MEDICAL JOURNAL* of February 11th (p. 205). It is perhaps just as well that I did not, for, in consequence, Sir Arthur was free to express his individual opinion of the recently discovered portrait which has been accepted and hung in the Royal College of Surgeons of England. Sir Arthur is sure that the painting represents John Hunter, and he gives his reasons with his usual lucidity and punctilious accuracy.

The picture was one of 157, the collection of Mr. McCormick of Hertford Street, sold at Christie's on December 1st, 1922. All were distinctly labelled and bore great names, which in the main were not justified by the prices obtained, but some were very fine, notably Sir Joshua Reynolds's "Captain Bligh," 260 guineas; a beautiful Th. de Keyser portrait of a lady, 250 guineas; and a gentleman by Raeburn, 230 guineas. Picture No. 131 had been labelled by Mr. McCormick "John Hunter, Esq., F.R.S., by Thomas Gainsborough," but in Christie's catalogue Gainsborough was not mentioned and the picture was attributed to one "Seton," whose name does not appear in any work of reference to which I have access.

No. 131 hung on Christie's wall for some days, and I went backwards and forwards to the College of Surgeons comparing the portrait carefully with the Reynolds life-mask of Hunter in the museum. To my mind the picture agreed with the mask in every particular. The wart, the shape of the nose, the skull, were all in the painting, and the colour of the eyes, grey-blue, and the slight squint all agreed with what I had read of Hunter's face. The painting was entirely in the manner of Gainsborough, the coat was in style and colour exactly what I knew Gainsborough was fond of, and so I bought the picture. During Gainsborough's fatal illness, of some months' duration, he was closely attended professionally by Hunter, and as we know that the artist painted to the very end of his life, how likely that he should ask his wonderful surgeon to give him a sitting. He painted Hunter exactly as he saw him, so faithfully described by Sir Berkeley Moynihan as a little ugly, red-haired, cantankerous Scot: The truthfulness of the portrait was probably distasteful to Mrs. Hunter, and it may have remained in the studio. When her husband died Mrs. Gainsborough quickly sold off everything, and the picture would easily be lost.

We know on the authority of Allan Cunningham that Gainsborough never signed his pictures and rarely dated them. I bought the portrait because I am convinced that it represents John Hunter, and I believe it was painted by Thomas Gainsborough.—I am, etc.,

London, W.I, Feb. 15th.

G. BUCKSTON BROWNE.

### THE ACUTE ABDOMEN.

SIR,—The admirable article by Mr. Flint in the *BRITISH MEDICAL JOURNAL* of February 11th (p. 209) omits, no doubt from want of space, reference to one very important early sign of a diffuse leak. This is the sign of reversed abdominal movements. In the normal patient, when the chest comes out the abdomen comes out (except in the first three breaths, which are self-conscious). If, however, the abdomen goes in when the chest comes out the patient has a perforation of some kind and a generalized involvement of the peritoneum. It is an earlier sign than rigidity, and many lives have been saved by its recognition.—I am, etc.,

Liverpool, Feb. 20th.

FRANK JEANS.

SIR,—In the correspondence columns of your issue of February 18th appear two letters criticizing my paper on the above subject, published on February 11th. Mr. Morrison takes exception to my use of the word rigidity as an indication of early mischief in the abdomen, preferring to

use the word resistance. He says this is no academic quibble. I venture to think it is. I grant there are degrees of abdominal rigidity both in respect of intensity and surface extent, but in all cases the term rigidity is perfectly correct. If Mr. Morrison will refer to a good dictionary he will find rigidity defined as the quality of resisting change of form, and I submit that exactly expresses the muscular state when an organ beneath is inflamed. Mr. Rankin also comments on this matter of rigidity. He says "It is regrettable that so many practitioners think there can be no acute lesion in the absence of rigidity." This criticism cannot be fairly levelled against my paper, for I state quite clearly that an acute appendix lying in the pelvis may be unaccompanied by rigidity of the anterior abdominal muscles, and also that it is not one of the early signs of acute obstruction of the intestine.

I would suggest to Mr. Rankin that if he wishes to criticize my paper he should read it again more carefully, and perhaps then he will not accense me of referring to faecal vomiting as one of the symptoms with which to diagnose an early acute obstruction, for the only occasion on which I mention faecal vomiting is when I say "faecal vomiting only occurs after the third or fourth day, and therefore has no useful place in diagnosis," and he may also find that I am one of "those who know what they are talking about."—I am, etc.,

Leeds, Feb. 19th.

E. R. FLINT.

SIR,—Mr. Flint's interesting article on the acute abdomen suggests to me the value of a cottage hospital staffed by local practitioners in the treatment of acute abdominal conditions and in the elimination of the "too late factor."

In the town of 12,000 inhabitants in which I live we have a hospital of this type; it is staffed by the local practitioners, amongst whom there is none of outstanding surgical ability. In the treatment of the acute abdomen this lack of special surgical ability seems more than compensated by the rapidity with which—because of our hospital—we are able to act. Our patients have little fear of accepting our advice quickly and of being treated in their homely local hospital by their own doctors. Because the town is a small one, and surgical results are therefore quickly known, the population is well educated in the advantages of early operation in acute surgical conditions.

On our part we brook no delay, and operate at once in order to save ourselves unnecessary difficulties. As a result of doing our own urgent surgery, we doctors get into the habit of making a definite diagnosis as quickly as possible, and of acting upon it; this habit carries itself into our general private work, and greatly increases the efficiency of all our medical work in the town.

Our figures during the two years in which the hospital has been at work are necessarily very small, and to that extent are an unreliable guide, but I believe that other small cottage hospitals throughout the country can produce similar figures. Our figures are:

	Cases.	Mortality.	
Acute appendicitis ...	25	Nil	0.0%
Pneumococcal peritonitis ...	1	Nil	0.0%
Strangulated herniae ...	3	Nil	0.0%
Perforated duodenal and gastric ulcers ...	7	Nil	0.0%
Acute obstructions ...	9	4	44.4%
Ruptured ectopic gestation	2	Nil	0.0%
Ruptured ovarian cysts ...	2	Nil	0.0%

Of these cases three acute obstructions, one ruptured ectopic gestation, and three perforated duodenal ulcers were operated upon by a surgical specialist. The mortality of the 47 cases is 8.3 per cent.

My own conviction is that the way to eliminate the "too late factor" in urgent abdominal surgery is to encourage general practitioners to undertake this type of work, which is often considerably less difficult than the complicated midwifery with which general practitioners habitually deal.—I am, etc.,

February 12th.

G. P.

## THE FUTURE OF OBSTETRICS.

SIR,—Dr. R. W. Johnstone (BRITISH MEDICAL JOURNAL, January 7th, p. 6) and previous writers have raised points of vital importance as to the part to be played by the midwife and by the general practitioner in the conduct of obstetrics. We have heard the opinions of specialists, we hear murmurings of discontent from some of the older established practitioners, but we do not hear much from those who have but recently entered upon practice fresh from a modern training. Now in all matters of progress the future must be given more consideration than the past, or even than the present—often a transitory state. May I, therefore, as one of only two years' experience in practice, offer my views on this important subject—views shared, I believe, by a good many of my contemporaries?

If we contrast obstetrics as carried on years ago and at present, we see that we have progressed from: A, an untrained, ignorant, and dirty handymaid, plus B, a general practitioner, trained and experienced up to a point but without aseptic surgical and other modern methods, to C, a trained and certified midwife, plus D, the modern general practitioner, who has trained in an atmosphere of preventive and aseptic midwifery.

What an advance is C over A! Equally all will admit that B and D bear little comparison. Surely, then, the more completely do we co-operate the two forces C and D the further and quicker do we climb up the hill toward ideal midwifery. The suggestion of Dr. Johnstone and other writers to dispense largely with D at the actual confinement in normal cases is, to my mind, a definitely retrograde step.

It does not take much thought to discover why, in the minds of Dr. Johnstone and other obstetrical experts, this suggestion has been fostered. It is, I think they will agree, largely owing to the fact that force D is not quite properly fulfilling its work; partly because the whole of force D is not at an equal standard of modernization (time alone will rectify that), but much more because D has not fully realized the advantages that the provision of C affords him. Equally C does not always realize the advantage of complete co-operation with D, and is too much inclined to look upon a case where the help of D has had to be called upon, either before, during, or after labour, as somewhat of a failure on her part.

Dr. Johnstone mentions as essential the ante- and post-natal examination and supervision of every pregnant woman by a medical man. This I am inclined to place as the most essential condition of real preventive midwifery, and it is being largely overlooked at the present time, as in a big number of cases carried through by midwives medical men are never consulted at any stage.

As things stand in our industrial areas at present the expectant mother may: (1) consult her doctor, in which case she receives supervision throughout (unless her doctor neglects his duty); (2) apply for admission to a hospital, in which case she probably receives ante-natal supervision from the hospital clinic, but post-natal supervision is more doubtful; (3) consult a private midwife, in which case she usually receives no medical supervision at any time; (4) consult the matron in charge of Association midwives, in which case she may be referred to her doctor for examination, but usually is not, being told that the services of a doctor are quite unnecessary, even sometimes after having expressed a wish for her own doctor to attend her as well.

The state of things in the latter two cases is one instance of the failure of each to realize the advantages of co-operation with the other. It would at once be rectified by all midwives, or matrons in charge of midwives, being required to refer cases to their own doctor for consultation.

To my mind the "family doctor" should be the first person sought by the expectant mother, or the first person to whom she is referred if she first consults a midwife. He should be primarily responsible for her condition throughout, and he can only be this if he actually attends at her confinement (in all but the very poorest of circumstances this is possible). His duties are, however, very different from what they were. He provides ante-natal supervision; he insists on the engagement of a certified midwife; should abnormal conditions be found he satisfies himself that

adequate help will be available or makes hospital arrangements; he attends at the confinement, but purely as a bystander if labour is normal; he carries out necessary post-natal examination and treatment.

Now this means to say that his midwifery is not the burden to him that it was in the days before there were competent midwives. At the confinement he is not compelled to waste hours; his patient realizes that he is engaged as a responsible overlooker of the job in hand. He has not the slightest incentive or excuse to resort to forceps unnecessarily, and he quite likely may not be present at the actual moment of birth. During the puerperium he is not obliged to visit as often, knowing that he can rely on his midwife. His fee is, under these conditions, quite adequate at the rate at present usual in industrial districts.

This, in my opinion, is the ideal way in which the midwifery of our industrial and suburban areas should and can be carried out. I do not consider that the establishment of municipal clinics for ante- and post-natal work is the right means to carry out the principle of ante- and post-natal supervision. Neither do I approve of sweeping large numbers of normal cases into hospitals. The ideal place for the birth, if normal, of the children of a family is the home, and the right person to supervise that birth is the family doctor. By the first confinement in the family more than all else does he gain the parents' trust, and it must ever be remembered that, by the trust of the individual family in their medical practitioner, so grows the trust of the community in the profession as a whole. This trust of the public in the medical profession has of recent years shown signs of weakening, and must be strengthened, as it is of fundamental national importance.—I am, etc.,

Halifax, Feb. 9th.

R. M. PEARCE.

#### SPECIALIST PUBLIC HEALTH SERVICES.

SIR,—A leading article in your issue of February 11th (p. 228) reviews the report by Dr. James Pearse (of the Ministry of Health) on "The co-ordination of the public health services in the counties of Essex, Hampshire, Gloucester, and West Sussex." Dr. Pearse's report raises some very important issues, particularly to the specialist public health services. By this "new way in public health" each sanitary district, or combination of two, three, or four sanitary districts, within the county has a medical officer of health who also acts over the same area for the county council as assistant school medical officer, assistant tuberculosis officer, and sometimes assistant maternity and child welfare officer.

How does all this affect the national campaign against tuberculosis? First, it must be pointed out that, of the four counties mentioned by Dr. Pearse, only two, Essex and Hampshire (and Essex only in part), have tuberculosis work undertaken by these "omnibus specialists." Secondly, the population of these areas covered by the one officer is very small; the average population of eleven of such areas in the county of Essex is 33,202. The scheme as outlined in your article makes one of the chief recommendations of the Departmental Committee on Tuberculosis (published in 1912, and known as the "Astor Report") impossible, for this committee definitely recommended that the tuberculosis officer of the dispensary should be a whole-time officer, of suitable age and attainment, and should be an expert on the subject of tuberculosis to command the confidence of the general practitioners. Is it possible for a medical officer of health who is responsible at the same time for all the services mentioned in Dr. Pearse's report to be a real specialist in tuberculosis? Will any general practitioner treat him as a consultant?

It is said that varied public health work in a combined district is less monotonous than specialized work, say, in tuberculosis. Surely the fault in other areas, where the work is said to be monotonous, is the lack of proper facilities to allow the tuberculosis officer to be a real specialist. If he does, as in some areas in England (and as he should do elsewhere), his own x-ray examinations and artificial pneumothorax work, and is in close touch with, or, better still, is in charge of, hospital beds—to say

nothing of non-pulmonary work—surely it is entirely false to say that such work can only be monotonous.

Much is often made of overlapping in county areas. If the county staff are real experts at their work the overlapping vanishes, because the smaller districts within the county accept the reports and work of the county authority. This is what actually occurs in Lancashire, and no doubt in many other areas.

Is it the policy of the Ministry of Health to support the scheme described and commended by Dr. Pearse, and to split up all the counties in England into small areas? Everyone knows the splendid tuberculosis work done in, say, Birmingham, Bradford, or Sheffield. Are the patients with tuberculosis, or those suspected of having tuberculosis, in a county area to have no chance of equal specialist advice and treatment?

Should not the present county dispensary areas be made much larger instead of smaller, to bring the general standard of county work nearer to the best county boroughs? Such areas would provide for a graded specialist tuberculosis service with varied work and better prospects, facilities for artificial pneumothorax treatment and artificial light treatment, the use of x rays for the purposes of diagnosis by the tuberculosis officer, and beds in one or more tuberculosis hospitals, under the care of the senior tuberculosis officer and his assistants for each area.—I am, etc.,

G. LISSANT COX,

Central Tuberculosis Officer, Lancashire.

Preston, Feb. 14th.

#### SHOCK AND ABORTION.

SIR,—There seem to be two kinds of shock: that in which death is immediate or occurs "in a few minutes," and that in which death is delayed for several hours, twenty-four or more. Shock caused by criminal abortion apparently belongs to the former category. "Senex" in his interesting letter (February 11th, p. 239) points out that since the passage of a uterine sound is ineffective, something more than the mere introduction of a foreign body is needed to set up "uterine shock."

Two factors are concerned in the production of the first variety of shock: (1) the mental state of the patient and (2) the effect of pain. Fright, fear, emotion may produce such an unstable state of the nervous system that the heart may be inhibited or stop on the least provocation. Pain, which may produce faintness, and in the case before us arises from dilatation of the internal os or distension of the uterus, may be that provocative. Shock caused by criminal abortion seems to be due to these causes, death being the result of an abnormal nervous reflex, conditioned by unstable nervous centres.

The same factors are at work in the rise of the other kind of shock, of which the post-operative variety is perhaps the best example. A patient who has made up her mind to die as the result of a forthcoming operation, or one who is unduly afraid, is more likely to suffer from and succumb to shock than the individual confident in her surgeon. But in this case the whole body becomes changed—there is something beyond a mere nervous reflex at work. The reaction of the tissue cells becomes abnormal, and the effect of these cells on the related capillary blood flow is thereby deranged.

A primary universal dilatation of the capillaries can hardly be supposed to be the cause of the sudden death in the first variety of shock. It thus seems reasonable to infer that the capillary dilatation of the ingravescens variety of shock is a secondary phenomenon. It is secondary to the deranged activity of the tissue cells—of striated muscle cells, of gland cells, of nerve cells.

All the tissue cells presumably are connected with the central nervous system, and their state of being conditioned by "trophic" impressions. If the mental state of the patient can inhibit the heart, fright or despair produced by the knowledge of a serious pathological process can presumably inhibit or derange the activity of other tissue cells. Added to this is the effect of the operative procedure itself, plus that of the anaesthetic. Anaesthetics affect not only cerebral cells, but presumably other cells. Morphine, so

the forceps were left in the body from want of care on Dr. Graham's part. But the mere fact that such actions at law are possible when surgeons are called upon to make instant decisions in the interests of the patient on the operating table is, to say the least, disquieting.

A point of some importance, not mentioned in the above account of the action at law, is that Dr. Graham himself reported the circumstances to the coroner, with the result that an inquest was held, when all the facts came out, and the verdict returned was death from natural causes—perforated gastric ulcer. The defence of the case was undertaken by the Medical Defence Union.

#### A CLERICAL ABORTION-MONGER.

THE "Jekyll and Hyde" career of the Rev. Francis Bacon, aged 70, who, while performing duties as vicar of All Saints, Spitalfields, was also, as "Howard Barron, LL.D.," carrying on three businesses which advertised and supplied varieties of treatment to pregnant women with the object of procuring abortion, ended in a sentence at the Old Bailey on February 20th of fifteen months' imprisonment in the second division.

It appeared that Bacon for many years had done good work in facilitating emigration among boys in the East End of London, and had taken part in voluntary missionary work and lecture tours in America. In 1917, while lecturing on war films, Bacon met a man named Carlton, who was similarly engaged, but who also ran the Powell Manufacturing Company, Limited, which gave advice and treatment to women in early pregnancy. An agreement was entered into between the two men whereby Carlton assigned half the shares in the company to Bacon. Apparently the concern proved profitable, for two further businesses, advertised as "Dr. Mary Lano" and "Hannah Brown, Ph.D.," were started with the same illicit object, the promoters employing a permanent manageress named Annie Bolton, daughter of a chimney-sweep, who was unable to follow her occupation as a school teacher owing to deafness.

When the police commenced criminal proceedings Carlton escaped to Bermuda, but Bacon and Bolton found themselves in the dock at the Old Bailey to answer charges of conspiring to supply noxious things to women knowing that they were to be used with intent to produce miscarriage. "Dr. Hannah Brown's female remedies" were variously classified as: "No. 1 treatment," price 5s., "No. 2 treatment," price two guineas, and "No. 3 treatment," price five guineas—the actual cost of the drugs being but a few shillings. The cumulative effect of these treatments was described by Sir William Wilcock, consulting medical adviser to the Home Office, Dr. Lynch, senior official analyst to the Home Office, and Dr. Malcolm Donaldson, gynaecologist, as likely to cause illegal miscarriage.

The cross-examination of Annie Bolton showed without shadow of doubt what was the real object of the businesses. Bacon and Carlton had said to her that it was breaking the law to send the treatment to pregnant women, but at the same time they drew a distinction between pregnancy of a few weeks and of some months. A stock letter was sent to all customers stating that the treatment was not for women who were pregnant, but "quite a lot" of the women who wrote for treatment said they were in the early stages of pregnancy. They were all supplied, and Bolton unhesitatingly agreed with the counsel who was cross-examining her that the stock letter was "eyewash." Bolton's damning admissions forced her counsel to withdraw her plea of "not guilty" and to enter a plea of "guilty." For his part Bacon threw the whole blame on the shoulders of the woman defendant. The stock letter, he said, was not "eyewash." Such a warning that the treatment was not for pregnant women was not an incitement to them to take it, and it was contrary to his intentions that Bolton sent the treatment to such women. He admitted he had no medical training. Why he chose the name of Hannah Brown was "because it was a good old family name" suitable for the business.

Bacon was subjected to searching questions by the Recorder on his use of degrees. His counsel had said he was given the LL.D. in Canada and the D.D. in the United States. In reply to the Recorder Bacon said that he used the business name of Hannah Brown, Ph.D., not to deceive the public, but rather to attract the public! Admittedly it was a false statement. Strictly, he supposed his description of himself on a pamphlet as "Howard Barron, D.Sc.," was a lie too, but "it is the ordinary commercial morality." The jury performed their plain duty in finding him guilty. Bolton received six months in the second division, as the Recorder felt that she had been carrying on the traffic too long for him to treat her as a first offender. Bacon's conduct was described by the Recorder as despicable and deplorable. Concealing an illicit traffic under the cloak of hypocrisy, Bacon had made money by preying upon the agony of poor expectant mothers, jeopardizing their health. A preacher of the Gospel, he had pleaded commercial

morality as an excuse for deceiving the public, and, most contemptible of all, he had sought to shield himself behind a subordinate.

The Recorder, in referring to the difficulties of the press, seems to have overlooked the fact that full information as to the nature of the traffic in remedies for "female irregularities" has been available to anyone interested in the subject since the publication of the report of the Select Committee on Patent Medicines in 1914. The committee recommended absolute prohibition, not only of all advertisements likely to suggest that a medicine is an abortifacient, but of all advertisements referring to sexual weakness. It also recommended legislation to prevent three very general practices of the vendors of these nostrums—namely, the enclosure with one remedy of printed matter recommending another, the invitation to sufferers to correspond with the vendor of the remedy, and the use of the name of a fictitious person in connexion with a remedy. Any newspaper manager sufficiently interested in the source of advertisement revenue to pursue the subject further might have learnt, from the evidence tendered to the committee by the representatives of what was held out as legitimate business of this nature, that no harm would be done by its total suppression. The report of the Select Committee deals very largely with methods of advertisement, and in spite of the general preoccupation with other matters at the date of its publication (August 4th, 1914), its existence should not be unknown to newspaper proprietors. In face of this fact it is difficult to agree with counsel for the Crown that "there was nothing in the wording of the advertisements to make the newspapers suspicious," or with the Recorder that "there was no blame to be attached to the newspapers," and that "the Press was placed in a very difficult position and did exercise a great deal of discretion and tact." In our opinion advertisements of this nature (however decently worded), which do not now appear in every newspaper, should not appear in any.

#### The Services.

##### DEATHS IN THE SERVICES.

Colonel Robert Hall Forman, Army Medical Service (retired), died in London on February 16th, aged 73. He was born at Halifax, Nova Scotia, on November 2nd, 1854, the son of J. R. Forman, C.E., of Craigpark, Ratho, Midlothian, and was educated at Merchiston School and at Glasgow University, where he was captain of the University Rugby fifteen. While still at college he obtained a commission as surgeon in the Imperial Turkish Army, and served in that capacity in the Russo-Turkish war of 1876-77. Returning to Scotland he qualified in 1877 as L.R.C.S.Ed. and L.F.P.S.Glas., and in the following year graduated at Glasgow as M.B. and C.M. Entering the army as surgeon on March 5th, 1880, he attained the rank of colonel on January 8th, 1906, and retired on November 2nd, 1911. After the great war began he rejoined for service on January 22nd, 1915, and served as inspecting officer on the staff of General Sir Francis Lloyd, commanding the London Division. He was a keen Freemason, and devoted much of his leisure to work on behalf of the craft. When he left India he held the rank therein of Grand Master of Scottish Lodges in India.

Major William Hunter Riddell, M.C., Indian Medical Service (retired), was accidentally killed by being knocked down by a motor on the Crieff-Muthill road, Perthshire, on December 27th, 1927, aged 45. He was born on September 22nd, 1882, and educated at Edinburgh University, where he graduated as M.B. and Ch.B. with honours in 1906. After studying in Paris, and filling the post of house-surgeon of the Staffordshire General Infirmary, he entered the I.M.S. as lieutenant on July 27th, 1907. He attained the rank of major on January 27th, 1919, and retired, on account of ill health, on April 4th, 1919. He served in the recent great war, was mentioned in dispatches in the *London Gazette* of July 27th, 1916, and received the Military Cross on June 24th, 1916.

#### Universities and Colleges.

##### UNIVERSITY OF OXFORD.

At a congregation held on February 18th the following medical degrees were conferred:

D.M.—E. W. N. Hobhouse, H. A. Gilkes, D. S. Davies.  
B.M.—R. Oddie.

##### UNIVERSITY OF LEEDS.

DR. A. MASSEY has been appointed Honorary Demonstrator in Public Health.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week gave the Companies Bill and minor measures a second reading. In reply to a question, on February 16th, the Home Secretary said that owing to pressure of business he was not at present able to introduce legislation on juvenile offenders and on sexual offences against young persons; he would see what could be done by administrative action. He hoped that a report would be published this year covering the work of the Children's Branch of the Home Office since publication of the last report in 1895. Supplementary Estimates were discussed on February 20th and 23rd, and an Empire Settlement Act Amendment Bill on February 24th. Debates regarding hospitals and medical affairs under the National Insurance Act arose on February 20th.

### Parliamentary Medical Committee.

At the first meeting of the Parliamentary Medical Committee for 1928, on February 14th, Dr. Fremantle was re-elected chairman; Dr. Vernon Davies (acting honorary secretary during the closing weeks of last session) being absent no honorary secretary was elected. The committee decided to try to arrange a visit to the army medical establishments at Aldershot, and also another visit to the Medical Research Council's institutions at Mount Vernon and Mill Hill. The committee further discussed the bill introduced by Sir R. Gower against experiments on dogs. A suggestion was made that amendments to the bill should be concerted between the committee and the Research Defence Association and put down. After a discussion on vaccination and small-pox the Medical Committee agreed to ask the Minister of Health to publish as soon as possible the report of the Committee on Vaccination. This report is understood to have been completed.

### Edinburgh Corporation Bill (Venereal Diseases).

Dr. Drummond Shiels drew the attention of the committee to the Edinburgh Corporation's Bill already laid before Parliament. The object of this bill is to secure further compulsory powers for dealing with venereal disease. (See this week's SUPPLEMENT, p. 66.) A letter from Mr. W. Graham relating to the bill was also before the committee, which took note of the fact that two of its members, Dr. Graham Little and Dr. Salter, had issued an invitation for members interested in the subject to meet and concert action in the House of Commons. The Medical Committee agreed that the bill raised questions of the highest importance, on which it could not then take a decision. It decided to invite representatives of the Edinburgh Corporation to address the committee regarding the bill on February 21st, or a later date.

On February 21st the spokesmen of the Edinburgh Corporation—Mr. Given (convener of the Public Health Committee), Mr. A. Grierson (town clerk), Dr. W. Robertson (medical officer of health), and Dr. D. Lees (venereal diseases officer)—met the Parliamentary Medical Committee. Dr. Fremantle presided and Dr. Drummond Shiels acted as honorary secretary. The town clerk of Edinburgh said that the corporation recognized the difficulties which critics of the bill suggested, but thought that the proposals made by the bill were the best which had been suggested to check the spread of venereal infection. Edinburgh asked permission to use these powers as an experiment. Certain members of the Medical Committee asked why Edinburgh did not secure compulsory notification of venereal diseases, as Bradford had done. The answer was that the corporation thought the proposals of the bill better, and in accord with the Trevethin report. The officials thought that, as Bradford had secured compulsory powers from Parliament without debate, Edinburgh was entitled to have its case heard before a parliamentary committee. They reported that at a conference of the large local authorities of Scotland all had declared themselves in favour of the Edinburgh proposals. The corporation was prepared to give some protection to doctors who reported suspected cases, and was ready to add a protective clause to the bill if this were desired. The discussion, which lasted about an hour and a half, showed that the Parliamentary Medical Committee was united in support of the objects of the bill, but no verdict on its proposals was suggested. (The statement for the Edinburgh Corporation which was the subject of debate by the Parliamentary Medical Committee and representatives of the Corporation is referred to in Scottish news at page 323 of this issue.)

### Certification under the National Insurance Acts.

#### Charges against Panel Doctors.

While the House of Commons was in Committee on Supplementary Estimates on February 20th, a discussion arose on the action of panel doctors in giving certificates to patients. The debate was on a Supplementary Estimate of £340,000 for the salaries and expenses of the Ministry of Health, including grants in aid in respect of benefits and expenses of administration under the National Health Insurance Acts. In the vote was included a sum of £210,000 for sickness, disablement, maternity, and other benefits, in addition to the original estimate.

Sir Kingsley Wood, in presenting the Estimate, explained that the £210,000 was necessitated by the continuing high expenditure on benefits by approved societies. There had been an increase in the number of attendances of insured persons for medical treatment, and claims for benefit had been made very freely, this state of affairs no doubt being accentuated in a time of considerable unemployment. It was a very disturbing feature. The Ministry of Health had taken every possible opportunity of reminding societies of the need of controlling the issue of insurance claims by such means as improved sickness visitation and the use of the regional medical services. The matter had been constantly discussed with the medical profession at many conferences, and the British Medical Association had the matter under close consideration as a result of a meeting with it on January 19th last. New regulations were brought into operation from October 1st, 1927, whereby a fortnight's delay was imposed on the transfer from one doctor to another, except where both doctors consented. That might have some material effect on these claims.

Mr. Rhys Davies said that they were informed that 150,000 persons had come into the health insurance scheme as voluntary contributors under the Widows' and Orphans' Contributory Pensions Act. This was about 10 per cent. above the estimate of the actuary. Proceeding to criticize the medical profession, he said that what they were failing to do accounted more than anything else for this increased expenditure. Three of the approved societies in Durham had complained about loose certification. So far as he was aware, no approved society declined a genuine claim for disablement or sickness benefit, but when they were suspicious that a doctor was giving medical certificates merely to increase the number of insured persons on his panel, the societies were entitled to say that that doctor should be stopped. In the course of the discussion they would no doubt be told that the panel doctor could not increase the number on his panel merely by granting certificates loosely. The Insurance Committee for the county of Durham had passed a resolution asking the Minister of Health to conduct an inquiry into this subject of loose certification. What was the Minister of Health doing about it? As a matter of fact, the Minister was afraid of the medical profession. When it was a question of dealing with a board of guardians they had heroes, but when the British Medical Association was "on the job," then the Minister quaked at once. (Laughter.) Was it true that this increased expenditure was partly due to the fact that the stamina of the people had deteriorated because of poverty and destitution? (Cries of "No.") Was it the experience of the approved societies that the increased sickness was greater in the distressed areas? That could easily be found out. He would give figures to prove that where a panel practitioner had a great number of persons on his panel he was not so careful in prescribing. Where a doctor had 2,500 persons on his panel the average frequency per insured person in connexion with prescriptions was 0.554; when he had fewer than 1,000 persons on his panel the average frequency was 0.237. There had been several allegations in Salford that doctors had been "touting," and he understood that there had been an inquiry into the allegations. He would like to know what was the result of that inquiry. He wished to add that the medical profession as a whole could not be charged with doing what he had suggested. They were not guilty of it, but only just a few, who ought certainly to be brought to book by the Ministry of Health, and made to do their duty to the State and to the approved societies.

Some approved societies, Mr. Davies said, had to realize their investments to meet the claims for benefit. That was the most serious aspect of the work of the societies, and this was the first time that they had been in that position. Were it not for the interest on their investments, the approved societies would now be heading straight for bankruptcy. In 1926 the total sum brought in by the approved societies' funds in contributions amounted to £27,000,000, and the interest on that was £1,000,000. A total of £28,000,000. Payments out for benefit amounted to £30,000,000, and the cost of administration was £5,000,000. That made a total of £35,000,000, and left a balance of only £2,000,000. The interest on investments of these societies ought to be safeguarded by the Minister of Health, but he had been browbeaten by the Chancellor of the Exchequer. Did the extension of the average age of the insured persons in the last decade account for the increase in the average rate of sickness? He wished to ask some questions on the work of the regional medical officer. Was it a fact that some panel doctors, who were in practice themselves, were also acting as regional medical officers? He took it for granted, of course, that a panel doctor did not become a judge of his own case. How many regional medical officers were there, and were they sufficient? How many regional dental officers were there? The work of these officers had been very good; were there sufficient to carry out

the task? The Minister of Health might consider the appointment of someone to act in the same capacity in relation to optical treatment and appliances as he had done in regard to dentistry.

Mr. Meller said that he was very glad to find that in his reference to the sickness experience of societies Mr. Davies had not alleged that there was unlingering among insured persons. Malingering in this country was very rare, and he believed that the malingering was made, and not born. If any unlingering had occurred in connexion with the sickness experience of societies in this country it had been due very largely to the lax methods which had been adopted by the medical practitioners. He joined with Mr. Davies in saying that, although the allegations which he had made with regard to doctors were extended only to a few, and although a very large proportion of them endeavoured to carry on their work quite fairly and properly, in the best interests of their patients, there were unfortunately many instances in which doctors had not paid that regard to the patient which they ought to have paid. They had been free enough to give medicine where medicine might not have been required, but slow in giving what he believed was very much better than many bottles of medicine—that was to say, to give a few healthy admonitions and send them about their business. The medical profession had said that their difficulty had arisen from the fact that they found it extremely hard to maintain the patients on their panel with the competition of other doctors in the neighbourhood. Many a man started to-day, not by buying his practice, but by putting up his plate and hoping that the number of insured persons would be fairly distributed in the district, and that he would get his share. It was not perhaps unnatural for him, when he was told that the patient was suffering from some complaint which he could not diagnose and which he could not disprove, to give him his certificate quite readily. There had been instances—and a good many, unfortunately—of medical men themselves saying that patients had come to them, and had said, “If you do not give the certificate I can get out down the street.” The medical man, in such a case, had found himself in the dilemma of either retaining the patient or seeing him go to another doctor down the street. In that way he might lose not only insured patients, but patients who were not insured persons. It was a difficult position, and unfortunately it seemed to be spreading. The best men in the medical profession were standing out against it, and wanted to stop it. He believed that the Ministry of Health was anxious to assist the strong doctor in resisting these unfair claims upon him and the unfair competition of certain men in the profession. He regretted very much the comparative ease of transfer from one panel doctor to another which had been allowed. Under the old system, when a period of six months or even a year was required, there was no hardship to the insured person, but it gave the doctor the opportunity of acting as firmly as he ought to act. The present practice, which gave the opportunity of transferring at any moment, with the consent of the late doctor and the proposed new doctor, or the other common practice that, with a fortnight's notice, a man or woman might transfer from one doctor to another simply because they might have been upset by something the doctor had said, was improper and ought to be stopped. Indeed, he believed that the medical profession was in favour of a longer period between the transfer from one doctor to another. The regional medical officers were set up some time ago because it was discovered that a very large number of claims were being made upon societies without any real grounds to justify them. Certificates of comparatively minor ailments, such as debility, continuing for some time, were given, and there was no satisfactory means of checking the doctor. Thereupon the Ministry set up regional medical officers. What had been the result? The report of the Ministry of Health for 1926 gave some figures with regard to the number of cases submitted for examination in that year. Some 420 cases were sent by societies to be examined by the regional medical officers, because the societies had some doubt as to the genuine incapacity of the insured persons concerned. There were 450,000 cases referred, and of that number about 60 per cent. either declared off before the examination or were found to be capable of work, while only about 40 per cent. of the people who had been referred by the societies were found to be incapable of work. It did seem that there was something wrong in a method of certification which allowed certificates to be issued in respect of 60 per cent. when they ought not to have been issued, and that only 40 per cent. of the cases were incapable of work. If it meant that further examination, further overseeing of the medical men, was needed, he hoped the request of Mr. Davies would be acceded to by the Ministry. Some reference had been made to the fact that certain of these examinations as part-time officers. In fairness to them it ought to be agreed that they did not examine within their own area, but medical referees entirely free from any suspicion, devoted only to the work of examining panel patients, and not having to bring by the apathy of the Ministry of Health.

Mr. Barker said that the condition of health in his constituency and in Monmouth generally was deplorable. There was more than quoted statistics from recent reports of the medical officers of health of Brynmawr urban district and of Nantyglo, and from more particularly for the county of Monmouth. Mr. Barker dealt in his opinion, partly due to lack of sufficient nourishment. The health of the working classes, he contended, was being endangered by the apathy of the Ministry of Health.

Dr. Vernon Davies said that there seemed to be in that debate rather a concerted attack upon members of the medical profession, which might to a certain extent have been justified, or might not.

One of the fundamental difficulties of the National Health Insurance Act was the question of certification and the free choice of doctor. The whole system of medical behaviour between doctor and patient had been altered. In the old days the doctor as a rule was the friend, helpmeet, and medical adviser of his patients, and his patients trusted and obeyed him. But the Insurance Act created a new state of affairs, and the medical man, instead of being the master, became the servant, and was now absolutely the servant of the insured population. They could take him on when they liked and dismiss him when they liked. Panel practitioners were human beings, and, in the majority of cases, had their living to earn. As a rule panel practitioners were as good or as bad as ordinary individuals, and they could be divided into three sections. There was the man who was conscientious, honest, and determined to do his best, and, at the other end of the scale, they had the man who was perhaps not so particular; he would not say that he was dishonest, but perhaps he was a little lax and careless. Between these two extremes was the man who wanted to do what was right, and was not able to do so. What was the reason? A patient came to the doctor to get a certificate. The doctor, if he was honest, as all doctors would like to be, gave a certificate if he thought that the patient was entitled to it. The difficulty did not occur at the onset of the illness, but towards the end, when the patient should go back to work. The doctor might think that the patient was fit for work, but the patient might think that he was not, and desire to draw benefit a little longer. The honest, conscientious doctor would cross the man off; but the doctor who was not quite so particular said to himself: “I might as well please my patient.” The other man perhaps said: “It is my object to have as many patients as I can, and if I can please my patients it does not matter about the national health certificate.” So long as they gave the patient the free choice of doctor they would be up against that difficulty. The difficulty did not always end there, because the man might have a family of five or six children who were private patients. The man might leave the doctor and not allow any of his family to go to him. Moreover, the same man might say to his friends that Dr. So-and-so was too particular and signed one off far too quickly.

The doctors undoubtedly were to blame in certain cases, and he had no desire to stick up unnecessarily for the medical profession. On the other hand, they must remember that they were putting very great temptations in the doctor's way. The doctor was in a very difficult position. He might be deceived by patients in certain cases if the patients wished to deceive him. On the other hand, the doctor was up against the approved societies, who were an extremely foolish body of individuals. An essential point in the administration of the Insurance Acts was that the medical man, the approved societies, and the chemists should work together, because their aims were the same—namely, to keep the insured persons healthy and to administer the funds to the best advantage. The approved societies did not like to pay benefit if they could help it, and when benefit was paid they were anxious that the patient should get off benefit as soon as possible. He would not say that they went spying round, but they sent their visitors, and if a poor woman happened to be lifting a kettle off the fire, or if she had a duster in her hand, or if a man happened to be out one minute after six o'clock, there was trouble. Instead of working with the medical men societies were too apt to send cases to the medical referee. He had found, over and over again, when he was in practice, that the majority of cases thus sent to the medical referee were the absolutely genuine cases, and the particularly doubtful cases had never been spotted at all. If the approved societies had asked his honest opinion they would have got it, and, in that event, they would have been able to send to the referee the proper cases. They had worked against the medical men because, in the old days of the club, they had the medical men under their thumb, and they had never forgiven the Ministry of Health and the Government for deciding that the doctors should not be put under the approved societies. It was absolutely necessary that they should make the right of free transfer very much more difficult than it was. No patient should be allowed to transfer without giving a specific reason. Mr. Rhys Davies had said that there had been a lot of over-prescribing. That was true; but again the doctor was in a very difficult position. If a patient said he was ill and wanted a bottle of medicine, and the medical man refused to give him one and told him to go home and do something that would do him good, the patient thought that he was not being properly treated, and that the doctor was no good. Such a doctor might find that a complaint had been made against him to the Medical Committee or the Insurance Committee, and that might cause him some trouble. Therefore, when a doctor had a discontented patient he gave a bottle of medicine. Fortunately, people were nowadays getting better educated, and recognized that medicine was not always necessary. At the same time there was in the industrial population the greatest belief in the efficacy of a bottle of medicine, and they could not afford altogether to neglect its psychological effect. He thought that a panel of 2,500 was far too many for any medical man. As a rule, doctors had private patients as well as panel patients. The danger was that a doctor might miss something, and then there was a scandal. But what was the doctor to do? If a doctor had 2,000 patients on his panel it meant about £800 a year. That sum did not go far, as the expenses of a doctor were appalling. The result was that a doctor must have a big panel to make it a paying proposition, and if they gave him a big panel he could not do the work properly. At some time or other he was bound to neglect it, and there would be complaints. “Touting” for patients was another curse of the Insurance Act. Since that Act came into force the standard of medical men had deteriorated, and there was not the same class of men coming into medicine to-day as there was fifteen or twenty years ago. Therefore they would get these

eases of "touting" where a young man anxious to make a practice would do something or other to get others in.

Mr. Whiteley said that there had been loose certification in Durham. There was a great desire in the county that there should be an inquiry. Something ought to be done.

Sir K. Wood, replying to the debate, said that the increase in the level of sickness had been pretty general, and was not characteristic of any particular industry. He wished to correct the view that had been put forward as to the number of insured people who were permitted to go on the panel of a particular doctor. The maximum number of insured persons permitted to a single panel doctor was 2,000. The average number of insured persons on doctors' lists up and down the country was not anywhere near 2,500, but about 1,000. It was a matter of considerable controversy and anxiety why the very large sum of money provided under the Insurance Act for sickness benefit should have been exceeded. It was true that the influenza epidemic did not wholly explain the persistence of high expenditure, and it might be that insured persons were looking more carefully to their rights under the Insurance Act, and that their claims for benefit were being made much more freely. The statements which he had made in that House twelve months ago had been very amply confirmed in all parts of the House that night. He found that the number of cases referred to the regional medical officers for a second opinion rose from 201,291 in 1921 to 377,180 in 1926, which was an abnormal year owing to industrial troubles, and was actually 313,011 in 1927. Comparing the figures of 1927 with those of 1925, he found that the number of persons referred to the regional medical officers had increased by 55 per cent. These were astonishing results, because the proportion of persons examined who were found to be capable of work had increased from 24 per cent. to 28.8 per cent. Another astonishing figure was that 44 per cent. of the people who were referred to the regional medical officers failed to attend the examination or declared off before the date of their examination, and the proportion of persons referred for examination who came off the fund, either by failing to attend or as the result of the medical examination, increased from 57.7 per cent. to 59.8 per cent. He was not going to endeavour to say who was responsible, whether it was the people who presented themselves for examination, or who failed to attend after notice had been given to them that their case was going before the regional medical officer, or whether it was due to faulty certificates by the medical profession. But these facts showed that the approved societies and the medical profession of the country had seriously to take this matter into account, because this excessive sickness was bearing on the approved societies, and the people who had to stand the racket in the end were the insured persons. It was only right that the greatest care and precaution should be taken in the administration of their affairs. The investigations into sickness ought to be of various kinds. In the first place, the Ministry had impressed on the approved societies their responsibility in the matter. In the second place, the Ministry had had a conference with the British Medical Association, which was engaged in an inquiry into this particular matter. Thirdly, the Ministry had advised the increased use of medical referees. The department was anxious to obtain, as far as possible, self-government by the approved societies, and that national insurance should be conducted by the societies themselves.

Mr. Rlys Davies: Is the right hon. gentleman aware that the approved societies have little control over the medical profession?

Sir K. Wood said that Mr. Davies knew the difficulties and delicate matters that obtained in a profession of this kind, but he thought that a very fair balance had been struck between the representatives of the approved societies on the one hand and of the great profession on the other. "You cannot," Sir K. Wood continued, "make the medical profession the servant of the approved societies, but, administering as they do an Act of this kind, they must be prepared to obey certain rules and conditions which I think are fair and sufficient. This discussion will serve a useful purpose in bringing these facts before the country, and the House has seen the serious state of affairs as far as sickness is concerned. The speech of Dr. Vernon Davies was a reasonable one, and did not disguise the seriousness of the position or the fact that there are a large number of people obtaining benefits which they ought not to obtain. Everyone who values the work of the approved societies must realize that these things must stop."

Dr. Watts remarked that he held no brief for the panel doctor; indeed, his personal opinion was that any man in the medical profession who accepted service under the National Insurance Act deserved what he got. The Act had had an ill effect on the health of the country generally. That Act was the greatest fraud ever perpetrated upon the country, and it should be repealed. In regard to certification, the panel doctor naturally took the line of least resistance, and accepted the statements of his patients, as it would be manifestly impossible to make a thorough and detailed examination in each case. Therefore it was unreasonable for members to blame panel doctors—foolish and misguided though they might be to take service under the Insurance Act. Unquestionably the approved societies had of late years been entirely wrong in their administration of the Act.

The Estimate was agreed to by 189 votes to 96.

#### Ministry of Pensions Hospitals.

The House of Commons, on February 20th, went into Committee of Supply on a Supplementary Estimate taken vote of £10 for expenditure in respect of sundry public buildings in Great Britain not provided for in other votes. Sir V. Henderson, Under Secretary to the Home Office (speaking on behalf of the First Commissioner of Works), explained that this token vote was really in connexion with the provision of hospital accommodation

in a new Ministry of Pensions hospital at Dunston Hill, Newcastle-on-Tyne. The new hospital would deal with general medical and surgical cases. The present hospital had been in use since 1920, but the accommodation there was more than was required. The present hospital accommodated about 450 patients, whereas the actual requirements at present did not exceed 120. The nurses employed at the hospital were quartered some distance away. It had been decided to re-house the patients and the nurses in one building, and arrangements had been made to take a lease for fourteen years of the old manor house and grounds known as Dunston Hill, five miles from Newcastle. The lease was determinable if necessary at the end of seven years. The cost of the alterations and works services would be £22,565. The building would house 120 patients and the nursing staff. The re-housing, so far as the nurses were concerned, would be complete by July of this year. It was estimated that there would be a saving on the new scheme of £6,800 a year. It was possible to deal with the matter by a token vote, the necessary money having been obtained from savings on certain other services.

Lieut.-Commander Keaworthy congratulated the Ministry of Pensions on deciding to remove this hospital out into the country. The lease of the new hospital, he said, was too short; it ought to have been for ninety years. After the hospital ceased to be necessary for the use of ex-service men it could be taken over by the Ministry of Health and used for the treatment of tuberculosis. There was a tremendous shortage of such hospitals on the North-east coast. He believed that the real solution of the difficulty would be to have Government hospitals in the future.

Sir V. Henderson said that it would be out of order for him to deal with the question of the future of the hospitals or the question of their control by the Ministry of Health. The Office of Works considered that a fourteen years' lease was sufficient. The new hospital would be well away from the road and the house stood in its own grounds. The House agreed to the vote.

Major Tryon stated, on February 16th, that the three Ministry of Pensions hospitals in Scotland—Bellahouston, Craigleith, and Edinbhall—held only 226 in-patients on February 10th, as compared with 557 on the same date in 1926. Arrangements had been made to close Craigleith hospital at an early date. The Ministry would retain hospital accommodation of the best quality in Scotland under its own control so long as it was needed.

Sir L. Worthington-Evans informed Colonel Woodcock that 3,454 beds were available in the military hospitals in this country; the maximum number occupied on any one date last year was 3,277, and the annual average occupied was 2,061.

#### Control of Venereal Disease.

Sir J. Gilmour, replying to Mr. Buchanan, on February 21st, said that since August, 1921, resolutions in favour of the general principle of compulsory notification of venereal disease, in one form or another, had been submitted to the Scottish Board of Health by twenty-nineburghal authorities, by combined venereal diseases authorities representing burghs in by the Convention of Royal Burghs at a deputation about a year ago, compulsory notification. In present sider that the exercise of such p... the Public Health (Scotland) Act, 1897, would be an appropriate method of dealing with the matter.

Mr. Buchanan asked whether, in view of the fact that certain corporations were approaching the House for powers, it would not be better, before anybody was granted any powers, that full inquiry into the subject should be instituted by the Department. Sir J. Gilmour: No, sir; much the best way would be to allow the matter to be discussed in the House. Mr. E. Brown asked whether the Secretary for Scotland had not also received a number of strong protests against the suggested course of action. Sir J. Gilmour said that he had received communications, both pro and con. Mr. Hardie asked if it was not against the best interests of government, either national or local, to do things by piecemeal, such as dealing with one town rather than another. Was it not better to have a full review, and then to legislate? The Speaker, inter-vening, said that that was a matter to be discussed on the bill itself. (See discussion on the Edinburgh Corporation Bill by the Parliamentary Medical Committee.)

**Dogs Act (Amendment) Bill.**—In this bill, introduced by Mr. Briggs, one subsection runs as follows: "Any person who takes possession of a stray dog shall forthwith either return the dog to its owner, or deliver the dog to a police officer of the police area in which the dog was found, and inform that officer where the dog was found." A fine not exceeding 40s. is prescribed for failure to comply with this subsection.

**Factory Inspectors in Scotland.**—Sir William Joynton-Hicks, on February 20th, told Mr. Buchanan that the staff of factory inspectors allocated to Scotland comprised nineteen inspectors and two inspectors' assistants. It was at full strength, except for a recent vacancy, caused by the death of an inspector, which would be filled shortly. The staff in 1914 consisted of sixteen inspectors and five assistants.

**Salaries of Medical Officers.**—In a reply to Captain Crookshank, on February 16th, Mr. Chamberlain said he had not consulted the law officers of the Crown about the refusal of his department to make grants towards the salaries of county medical officers and other medical persons unless such salaries were in accord with the schedule of the British Medical Association. He was aware that the Lindsey County Council was dissatisfied over such a case. Captain Crookshank asked whether the Minister would now modify his action seeing that the Trade Disputes and Trade

Unions Act, 1927, forbade local authorities to lay down the condition that their employees should be members of trade unions. Mr. Chamberlain said the Act contained such a provision, but he did not think it applied to this case.

**Wingfield Orthopaedic Hospital.**—In reply to Sir Robert Hamilton, on February 16th, Lord Eustace Percy said that on April 7th, 1927, the medical inspectors of the Ministry of Education, at the close of their inspection of the Wingfield Orthopaedic Hospital, Headington, Oxford, conferred with the house committee at the request of that body, and in the course of the discussion commented adversely on the efficiency and suitability of the secretary of the hospital and of the manager of the workshops. The inspection was under the Education Act and in accordance with the usual practice. Action subsequently taken by the managers was at their own discretion.

**Tinned Foods.**—The Minister of Health is advised that the nutritive value of tinned foods is, in general, comparable with that of other cooked foods. He has no evidence suggesting the necessity for him to set on foot expert inquiries into the effect of these foods on the public health.

**Infant Death Rate in County Durham.**—Mr. R. Richardson, on February 16th, asked if Mr. Chamberlain's attention had been called to the report made in December, 1927, by the medical officers for Chester-le-Street and Houghton-le-Spring, and again in January for Houghton-le-Spring, to the effect that the infantile mortality rate in Houghton-le-Spring was over 200 and in Chester-le-Street 147. Mr. Chamberlain said he had not officially received these reports, but would obtain them. Mr. Richardson asserted that medical officers in various parts of Durham had reported increases in the infantile mortality rate, and had expressed the opinion that it was largely due to lack of nourishment for mothers and children.

#### Notes in Brief.

Three out of the necessary seven signatures by members of the Council of the League of Nations are still lacking to the International Opium Convention, signed at Geneva in February, 1925.

On February 20th Sir Shirley Benn presented a bill to amend the law relating to the marriage of persons with their nephew or niece by marriage, and it was read a first time.

There were 1,224,140 lb. of opium exported from India in 1926, including 88,000 lb. of medical opium sent to this country. In the same year the produce of the acreage in British India was 1,682,700 lb. Figures for 1927 are not yet available.

Twenty-six nursery schools are at present recognized by the Board of Education. The provision of two others has been approved, one of which is now in course of erection.

## Medical News.

**THE Hunterian Oration** will be delivered before the Hunterian Society of London at the Mansion House on Monday next, February 27th, at 9 p.m., by Dr. Anthony Feilding, on "Sciatica: its varieties and treatment." The Hunterian Society of St. George's Hospital has invited the Hunterian Society to take part in a joint commemoration of the bicentenary of John Hunter. A special meeting will accordingly be held in the board room of St. George's Hospital on Thursday, March 1st, at 9 p.m. The meeting will be in the nature of a conversation, and short addresses will be delivered by Sir Humphry Rolleston and Sir Crisp English.

As a sequel to the conference on maternal mortality at the end of last October a further meeting will be held at the Central Hall, Westminster, on February 28th, at 3 p.m., when Mr. Arthur Greenwood, M.P., will speak, and the Hon. Mrs. Alfred Lyttelton will take the chair. It will be proposed that steps should be taken to obtain a medical inquiry into every maternal death due to childbirth; that further instruction in midwifery should be introduced into the medical curriculum; that an official committee should be appointed to consider the training and employment of midwives; that the provisions of the National Health Insurance Acts should be modified to make medical and midwifery services available for mothers, both for ante-natal care and during and after confinement; and that local authorities should be encouraged to make their maternity services adequate.

**THE post-graduate course of lectures and demonstrations at the Manchester Royal Infirmary** will be resumed on March 2nd, when Dr. A. H. Holmes will give a demonstration of medical cases. On March 6th Mr. Howson Ray will lecture on mucous colitis. The lectures and demonstrations, which are free to members of the medical profession, will begin at 4.15 p.m. each day, and tea will be served at 3.45.

**A COURSE of three post-graduate lectures on cancer** will be held at the Leeds Medical School on Wednesdays, March 7th, April 4th, and May 9th, at 3.30 p.m. Sir Berkeley Moynihan will deliver the first lecture, which will be of an introductory nature; Professor G. E. Gask will speak in April, on radium in the treatment of malignant disease; and Professor G. Grey Turner will deal with cancer of the rectum, in May. Those

who intend to be present are asked to inform the secretary of the British Empire Cancer Campaign, 47, Park Square, Leeds, at least two days before each lecture. The course is free to medical practitioners, and tea will be provided.

**THE Fellowship of Medicine** announces that Dr. Neill Hobbonse will give a lecture on aetiology in relation to cerebral disease and abnormality on February 27th, at 5 p.m., at the house of the Medical Society of London, 11, Chandos Street, W. There will be a demonstration in surgery by Mr. Aleck Bonrue at the Samaritan Hospital for Women on February 29th at 2.30 p.m., and Dr. Heald will demonstrate on cases treated by electro-therapy on the same day, at 5 p.m., at the Royal Free Hospital. The lecture and the two demonstrations are free to medical practitioners. From March 5th to 17th there will be three courses as follows: in diseases of children at the Queen's Hospital, taking up the whole of each day; in gynaecology at the Chelsea Hospital for Women, occupying some mornings and some afternoons; and in ophthalmology at the Royal Eye Hospital during the afternoons only. From March 19th to 24th there will be an all-day course in diseases of the chest at the Brompton Hospital. From March 19th to 31st a course in orthopaedics will be held at the Royal National Orthopaedic Hospital in the mornings and afternoons, and a practitioners' course in medicine, surgery, and the specialties in the late afternoons at the Hampstead General Hospital. The April courses begin on the 16th of that month. The general course of work, consisting of attendance at the ordinary practice of some forty London hospitals, continues without interruption. The programme for this course and the tickets, which may be taken for any period from one week to one year, together with the syllabuses of the special courses, may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

**A POST-GRADUATE course in recent advances in pediatrics** will be held under the auspices of the Paris Faculty of Medicine at the Hôpital des Enfants-Malades, 149, Rue de Sèvres, from April 2nd to 14th. The fee is 250 francs, and further information may be obtained from the secretary of the Faculty of Medicine, 12, Rue de l'École de Médecine, Paris.

**THE Council of Industrial Medicine** has arranged a meeting for Friday, March 2nd, at 5.30 p.m., at 12, Stratford Place, W., to discuss the treatment of industrial accidents and the value of adequate treatment of industrial rheumatism.

**THE Irish Medical Schools' and Graduates' Association** will hold its annual London dinner on Saturday, March 17th (St. Patrick's Day), at 7.45 p.m., at the Savoy Hotel, when the guest of honour will be General Sir Hubert Gough. The honorary dinner secretary is Dr. F. R. Holmes Meyrick (59, Kensington Court, W.8).

**ALMOST simultaneously with the appearance of Sir Leonard Rogers' paper on small-pox and climate in England and Wales in our present issue** there has been published by the Oxford University Press his Robert Boyle Lecture on "Climate and disease incidence in India: forecasting epidemics," delivered last June. The price of the pamphlet is 1s.

**This week's issue of the Autocar** is intended especially for new motorists; its contents include notes on learning to drive a car and a classified buyer's guide.

**THE Bishop of Willesden** preached at St. Andrew's Church, Holborn, on February 19th at the thanksgiving service for the centenary of the Royal Free Hospital; the Lord Mayor was present, together with the Mayors of Holborn, Finsbury, and Islington. The Bishop described the origin of the hospital, to which we referred on February 11th (p. 236), and commented on the valuable work it was now doing, particularly in the education of women for medical practice.

**THE first congress of the German Society for Researches on the Circulation** will be held at Cologne on March 5th and 6th, and the German Balneological Congress will be held at Baden, near Vienna, from March 28th to the 31st.

**THE medical visit to Prague and the Czechoslovakian spas last Easter**, of which some account appeared in our issues of May 14th, May 28th, and June 4th, 1927, is to be followed this spring by a tour through several Yugoslav provinces. We gather that it will be more of a pleasure party than a professional expedition, the only place with a special appeal to doctors being the Rockefeller Institute at Zagreb. The journey out and home will be by way of London, Harwich, the Hook of Holland, and Munich; apart from this all the travelling will be in motor cars. A most attractive itinerary has been arranged, and places in Yugoslavia will be visited which ordinary tourists rarely see. The party is due to leave on April 3rd and return on April 24th; the charge will be £41 16s., to include all travelling expenses, motor cars, hotels, and tips. Wives or daughters of medical men joining the tour will be welcomed. Typed particulars of the route, with information about passports, postal arrangements, and so on, may be had from Mr. Henry Baerlein (the Bath Club, 34, Dover Street, London, W.1), who organized so successfully last year's travel in Czechoslovakia.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Pacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

### QUERIES AND ANSWERS.

#### FIREMEN'S CRAMP.

**DR. R. S. MORSEHEAD** (Shoreham) writes: "Ship" (February 18th, p. 291) will find a most interesting account of "Firemen's cramp" in *Possible Worlds*, by J. B. S. Haldane.

"E. L. M." writes: An answer to the query of "Ship" will be found in an article by Dr. A. Vavasour Elder in the *Medical Press and Circular* of October 7th, 1925. The writer advises the addition of 3 drachms of common salt to the gallon of water for drinking, and the avoidance of lead water as much as possible. The recommendations are based on the researches of Sir Josiah Court and Professor K. Neville Moss on miners' fatigue.

#### CLEANING DENTURES.

"L. M." writes: I find that the deposit is all removed by leaving the dentures at night in half a tumbler of water, to which a small quantity, say half a teaspoonful, of concentrated ensoil has been added; "milton" will do as well. Of course, the dentures should be first washed with soap and water to remove any grease. With a nightly soak in ensoil and water there will be no further trouble; if the deposit is very thick it will take a few nights to remove it.

#### INCOME TAX.

##### Cash Basis for Gross Income.

"M. B." has hitherto been assessed for income tax on the basis of cash receipts; he has recently bought a new practice—the book debts have not been taken over—and the inspector of taxes now declines to accept the cash basis.

"M. B." cannot successfully appeal in such circumstances. The cash basis is admittedly incorrect in theory, but is accepted in practice where the circumstances are such as to create the assumption that the value of the year's bookings unpaid is about equal to the cash received for work done in previous years. He should, however, claim a reasonable amount as a deduction from outstanding debts in respect of the amount which he will probably not receive, and he should not pay tax on cash received for work done in prior years—for example, if he has given up his former practice the cash receipts therefrom no longer affect his income tax liability.

##### Subscriptions to Societies.

"A. A. C.," who writes from an infirmary, and whom we therefore assume to be assessed under Schedule E, inquires as to the allowance for subscriptions to the British Medical Association and scientific societies.

The point was before the High Court in 1925 in the case of *Simpson v. Tate*, when Mr. Justice Rowlatt declined to accept the argument that such expenses were necessary to obtain the periodicals requisite for professional work. In that case it was not a condition of Dr. Tate's employment as county medical officer that he should be a member of the bodies in question. If that condition can be shown to apply to "A. A. C.'s" employment he would be on stronger ground, and we believe that in such circumstances the Board of Inland Revenue would admit the claim to deduct the subscriptions.

### LETTERS, NOTES, ETC.

#### DRUG TREATMENT OF PNEUMONIA.

**DR. D. M. MACDONALD** (Ayrside, Westmorland) writes: In spite of Dr. Maddlow's clever satire (*JOURNAL*, February 11th, p. 238) on the absence of satisfactory drug treatment in pneumonia, I endorse the experience of Dr. Wiggins, which also appeared in that issue, with reference to the undoubted efficacy of the prescription containing creosote and potassium iodide. I cannot claim his 100 per cent. successes, and attribute the failure, first, to delay in seeing the patient in the early stage of the malady, and, secondly, to the presence of complications. If I remember rightly, the prescription was contributed to your columns by Dr. Mathison, who also furnished me with a modification of the mixture for the disease in children, as follows:

A child aged 12 would get one-half the dose of an adult.	
" 6 " "	one-third " "
" 4 " "	one-fourth " "
" 1 " "	one-twelfth " "

Dr. Mathison opens treatment with a dose of calomel; I have not used the saline mixture given at intervals between doses of the above prescription, but the use of Dover's powder at bedtime is extremely helpful. I have given increasing doses of the iodide alone, and creosote by itself, but in my opinion the results never equal the two in combination. I would suggest that Dr. Maddlow give the prescription a fair trial and report the results in a future issue of the *JOURNAL*.

#### RUNNING AS A RECREATION.

**DR. F. E. FREMANTLE, M.P.**, contributes to the February issue of the *L.A.C. News*, the official publication of the London Athletic Club, an interesting note on running as a recreation, in which he advocates popularization of this healthy and inexpensive form of exercise. He believes that breakdown in middle life may be prevented by cross-country running, and pleads for the opening up of the neglected bridle paths for this purpose. In the course of a life he—like the late Dr. H. in 1895—has found that heart and did not interfere with this form of sport. The possibility of ensuring the preservation of the heart and circulation in good order by even a short run every day certainly deserves consideration in these days as an economical form of recreation, and Dr. Fremantle looks upon it as "one of the surest means of enjoying and prolonging life."

#### DANGEROUS DRUGS.

**COLONEL W. G. FRIDMORE, I.M.S. (ret.)**, writes: Is anything being done to extend the utility of the Dangerous Drugs Act? It is not sufficient to obtain opium and its derivatives or its prescription, and then only with special licence; it should be, but almost anyone can go into a chemist's shop and buy euphonia, the quantity varying with the desire of the buyer and respectability of the chemist. Some will sell twenty-five tablets of 5 grains each without question: Some, whose sense of honour is a little higher, will say, "Of course, your doctor knows that you are taking this?" Some will refuse to sell any. But there are many chemists who will sell without a question, and all the drug addict has to do is to visit half a dozen chemists to collect the same number of bottles, each containing twenty-five tablets of 5 grains each. This I know is being done by a young girl patient of mine. Why are not the same precautions necessary with sulphonal and the barbitone group as with morphine and cocaine?

#### RECORDS OF CANCER CASES.

"L. S. A." writes: Dr. Grainger's letter in your issue of January 21st (p. 117) brings to mind a contribution by Sir D'Arcy Power to the *Cancer Number of the Practitioner* of April, 1893, p. 418, which, perhaps, I may be allowed briefly to epitomize. In a village, not named, so many cancer cases had occurred that he went down and investigated the neighbourhood as well as the cases. He found local circumstances in such marked relation to the houses where cancer had occurred that he ended his communication thus: "It will almost certainly prove that there is some intermediate host whose chance of detection will increase or diminish with the care which is taken to examine the fauna and flora of the districts where cancer is most prevalent." Is it not glaringly obvious that where the "causa causans" is in and of operation is the very place in which to seek for it, and that the presence of any accomplice may lead to discovery? Why is not this local clue thoroughly followed up?

#### MOSQUITO BREEDING AND POOL-PROOF GUTTERING.

**DR. F. G. CAYSTON** (Durban) writes in reference to the tapered guttering advocated by him in a letter published in our issue of January 7th (p. 38): "The model and plans . . . have been shown at a meeting at the Colonial Office of the Colonial Advisory Medical and Sanitary Committee, and have been presented to the museum of the London School of Tropical Medicine, where they will be exhibited."

#### VACANCIES.

**NOTIFICATIONS** of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 50, 51, 54, and 55 of our advertisements columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisements columns appears in the *Supplement* at page 67.

## An Address

ON

## THE PRINCIPLES OF DIAGNOSIS.\*

BY

ROBERT HUTCHISON, M.D., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL.

It is written that there abideth Faith, Hope, Charity, these three, but the greatest of these is Charity. And so in Medicine we have Diagnosis, which is a matter of faith; Prognosis, which is a question of hope; and Treatment, which is only too often an affair of charity; but the greatest of these is Diagnosis. For without accurate diagnosis it is impossible to forecast the course and outcome of a disease or to treat it satisfactorily. Indeed, as someone has truly said, "The first part of treatment is diagnosis, and the second, diagnosis, and the third, diagnosis." I need make no apology, therefore, for directing your attention to some reflections on such an important subject on this occasion.

Diagnosis is based on an accurate interpretation of symptoms and signs. I am aware that there has been in recent times an attempt to ignore any distinction between these and to speak of all the manifestations of disease as symptoms. I think there is an advantage, however, in keeping to the old division and to call "symptoms" all the subjective results of disease which are described to you by the patient, and "signs" all the objective phenomena which you discover on physical examination. It is true that there are some manifestations of disease which occupy an intermediate place between symptoms and signs—disorders of sensation, for instance—but this does not invalidate the general utility of keeping the subjective and the objective separate.

Symptoms are elicited by taking the history and by the cross-examination of the patient upon it. This is the patient's contribution to the making of the diagnosis, and its value cannot be over-estimated. The importance of the symptoms—and therefore of the history—in the diagnosis varies greatly in different cases, but it is perhaps greatest in cases of abdominal disease, and least in cutaneous diseases and organic disease of the nervous system. If you are dealing with a stupid, deaf, or confused patient, or one who has little power of expressing himself in words, your difficulty in eliciting symptoms may be very great. Inasmuch, however, as the whole diagnosis may depend upon your success it is worth while to exercise great patience and to spend much time in the cross-examination.

All symptoms are not of equal diagnostic importance, and in the case of voluble patients a good many of them may safely be ignored. There is usually one symptom, however, which troubles the patient more than any other, and to this the term "presenting symptom" is sometimes applied. Special attention should always be given to it. Although it is a good rule not to ask leading questions when taking a history, it is legitimate—once a preliminary diagnosis has been made on the presenting symptom—to ask for "corroborating" symptoms which the patient may not have specially observed or which he may have omitted to mention.

The detection of signs depends upon observation and training in clinical methods of investigation, both general and special. It may be doubted whether ordinary bedside observation of the signs of disease is as good now as it was a generation or two ago—in the time of such men, to mention only two who were at my own hospital, as Jonathan Hutchison and Hughlings Jackson. There is, I believe, a real danger lest the increased use of laboratory tests, x-ray examinations, and other short cuts to diagnosis should lead to a neglect of the information to be obtained by the skilful use of the unaided senses, and to a comparative atrophy of these from disuse. Most clinical teachers must be aware of this.

There are two sorts of error in diagnosis by signs—one

negative, the other positive. Negative errors are perhaps commonest, and arise from overlooking signs which are present; they are chiefly made by those ill trained in clinical methods. Positive errors consist in detecting signs which have no real existence—the discovery, in short, of mares' nests. They are chiefly made by those with observational zeal but little knowledge or experience. The apex of the right lung, the pulmonary area of the heart, and the right iliac fossa are the regions in which mares' nests are specially common.

Having elicited the symptoms and signs which are present, knowledge is necessary in interpreting them, for without knowledge one is "mind-blind." I remember well the first case of encephalitis lethargica which I saw, just when the disease was beginning to appear in this country. The symptoms and signs were obvious enough, but the assemblage of them meant nothing. I could not put a name to the disease, and it was only after the publication of cases by Professor Arthur Hall and others that I recognized, retrospectively, what I had been dealing with. Such mind-blindness may at times affect one even as regards a disease which one has seen before, as the result of temporary fatigue; for, as Dr. Samuel Johnson remarked, "Sudden fits of inadvertency will surprise vigilance . . . and casual eclipses of the mind will darken learning." Seen again next day, when one is fresh, the whole clinical picture at once falls into focus.

After observation and knowledge comes judgement as a factor in the making of a diagnosis; indeed, I believe it to be in some respects the most important factor of the three. Every doctor must be a judge. He has to weigh the evidence of symptoms and signs, and allot to each its proper value in making the diagnosis. Now we have Hippocratic authority for the belief that "judgement is difficult," and, indeed, medicine has been defined as "the art of coming to a conclusion on insufficient evidence," so it need be no matter for surprise that errors of judgement so often lead to erroneous diagnosis.

We can increase our powers of observation by training and practice, and we can extend their range by means of special instruments and methods. We can increase our knowledge by study and experience, but can we improve our powers of judgement? I greatly doubt it. Judgement seems to be an inborn faculty, the result of a union of mind and character, which a man either has or has not, and it is almost as difficult for him to increase it as to add an cubit to his stature. As Stephen has said:

"The one talent which is most worth all other talents put together in all human affairs is the talent of judging right upon imperfect materials, the talent if you please of guessing right. It is a talent which no rules will ever teach, and which even experience does not always give. It often coexists with a good deal of slowness and dullness, and with a very slight power of expression. All that can be said about it is, that to see things as they are, without exaggeration or passion, is essential to it; but how can we see things as they are? Simply by opening our eyes and looking with whatever power we may have. All really important matters are decided, not by a process of argument worked out from adequate premises to a necessary conclusion, but by making a wise choice between several possible views."—Stephen's *Liberty*, etc., p. 332.

What is sometimes called "clinical instinct" is, in truth, simply a power of rapid instinctive judgement, and it may be lacking in men of high intellectual ability and present to a marked degree in those who are in other respects mentally their inferiors. It seems to be much the same as "common sense" and closely allied to a sense of humour, which is the same thing as a sense of proportion. Those who lack it are apt, in making a diagnosis, to fail to see the wood for the trees.

If the natural powers of judgement are to be improved it is only, I believe, by general mental culture, and not by purely scientific training, that it can be done. The study of "humanism," by which is meant the philosophy of knowledge as opposed to its practical application, must be the means. As someone has said, sanity, humour, breadth of view, and powers of criticism are the distinguishing marks of the humanist, and it is at these that we must aim. It is for this reason that I regret the modern tendency to make the scientific studies of the

\* Delivered before the Midland Medical Society, October 27th, 1927.

Secondly, Don't diagnose rarities. Remember the saying of that wise physician Samuel Gee, "Common things of most commonly occur." I was associated for a time in my early days with a physician who had acquired a reputation in the diagnosis of unusual and rare cases, although, as a matter of fact, he was oftener wrong than right. I remember going round the wards with him one day when he pointed to a sudden elevation of temperature in a chronic case of pulmonary disease and inquired its cause. I replied that I believed it was due to the patient having developed an ischio-rectal abscess, as he had a tender swelling in the usual situation. "Well," he replied, "I have seen an empyema point there." When at a consultation I hear a doctor begin "I once saw a case," etc., I know he is going to make a bad diagnosis. Cases

so uncommon as only to be seen once are not likely to be seen again.

Thirdly, *Don't be in a hurry.* Wait till you have all the facts, remembering that a laboratory report (for example) may at the last moment upset all your calculations. Reserve your decision, therefore, in a difficult case; take it, as the Scotch lawyers say, "to avizandum." If you come to a premature conclusion it is difficult to alter it afterwards, not only because it involves awkward explanations to the patient, but because, by the mere fact of having made a diagnosis, you become insensibly biased and more impervious to the reception of fresh evidence. It is for this reason that all "snap-shot" diagnosis is to be condemned. It is impressive but perilous. "Life," as Dr. Johnson said, "is not to be sacrificed to an affectation of quick discernment, or of crowded practice, but may be required, if trifled away, at the hand of the physician."

Fourthly, *Don't be faddy.* This is the besetting sin of the specialist. He sees only what he is always seeing and what he wants to see. To the cardiologist few hearts are healthy; to the tuberculosis expert no lung is sound. The syphilographer sees disease only in terms of syphilis; the psycho-analyst only in those of sex. Beware, therefore, when you find yourself always diagnosing the same thing; beware also of the "stunt" of the moment—"avitaminosis," "foetal sepsis," "disturbance of endocrine balance," or what not. Try to see the case steadily and see it whole.

Fifthly, *Don't mistake a label for a diagnosis.* Such "diagnoses" as "gastritis," "neuritis," "influenza," "neurasthenia," are, more often than not, mere labels; they have no essential relation to reality. It may be necessary in the exigencies of practice, and in order to satisfy the patient's mind, to use such labels for a time, but don't let them deceive you into thinking that you understand the nature of the case. Be mentally honest.

Sixthly, *Don't diagnose two diseases simultaneously in the same patient.* Remember the law of "paucity of causation." Don't, for example, explain some features of a case by a diagnosis of cancer and others by assuming the presence of tuberculosis. There is, of course, no reason why patients should not run two diseases simultaneously, but as a matter of fact they rarely do. Make it a rule, then, if you possibly can, to account for all the clinical features of the case by assuming the presence of only one pathological process.

Seventhly, *Don't be too cock-sure.* "Think it possible," as Cromwell said to the Scotch bigots, "that you may be mistaken." On the other hand, don't hesitate too long between two alternative diagnoses, like the proverbial ass between two bundles of hay. Cock-sureness in diagnosis is the vice of the inexperienced; excessive caution that of the man who has seen too much.

Eighthly, *Don't be biased.* Avoid preconceptions. Approach every case with an open mind, and don't listen to the opinion of others, even that of the relations or nurse, till you have formed your own. This is the main reason for consultations: the consultant approaches the case, or should do so, with an open mind. It is also the justification for the layman's desire for "an independent opinion"—that is, for the opinion of one who is approaching the case fresh and without any preconceived ideas about it.

Finally, *Don't hesitate to revise your diagnosis from time to time in a chronic case.* Things may change, new signs may appear which put a totally different complexion on the matter, and the original and provisional diagnosis may no longer be able to stand. I was once told by a shrewd and experienced practitioner that he made it a rule always to re-examine his patient on the morning of a consultation. On the one occasion when he omitted to do this he was badly caught out.

In conclusion, let me say that it is quite impossible that you should always be right in your diagnosis, if only for the reason that disease does not always play the game. It is better, however, to be wrong on sound principles than right by chance. Guessing is to be avoided at all costs; for if you once get into the habit of guessing you are diagnostically damned.

## RAIN-BEARING WINDS AND EARLY PHTHISIS IN DERBYSHIRE.

BY

W. GORDON, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL;

AND

W. M. ASH, M.B., B.S., F.R.C.S.E., D.P.H.,

COUNTY MEDICAL OFFICER OF HEALTH FOR DERBYSHIRE.

THE county of Derby provides a remarkable proof of the effect of strong prevalent rain-bearing winds upon the course of early phthisis, amply confirming the recent evidence from Devonshire and West Shropshire. Incidentally it also furnishes interesting indications of an effect of subsoil on the course of phthisis which will not surprise those who have followed the work already published regarding the effect of subsoil on the prevalence of the disease. We shall set forth our findings as briefly as we can.

We have dealt with 306 first-stage cases, which had been treated at the County Sanatorium (near Chesterfield), and followed at their homes for four years after their discharge, as was done with the cases in Devonshire and West Shropshire. The results for the whole county of Derby, taken as a unit, are as follows: in respect of south-west, west, and north-west winds—

### Mortality.

Sheltered cases	...	...	...	...	6.96%
Exposed cases	...	...	...	...	14.13%

or, confining attention only to the indisputable cases—that is, deaths certified as due to phthisis and living cases in which tubercle bacilli had been discovered in the sputum:

Sheltered cases	...	...	...	...	14.05%
Exposed cases	...	...	...	...	28.72%

### Arrests.

Sheltered cases	...	...	...	...	68.69%
Exposed cases	...	...	...	...	63.87%

or, considering only indisputable cases, as above:

Sheltered cases	...	...	...	...	61.39%
Exposed cases	...	...	...	...	41.49%

These figures, significant as they are, do not, however, show the real extent of the contrast, because of certain peculiarities of the geology, configuration, and rainfall of the county, which we shall now explain.

### Access of Westerly Winds.

Derbyshire lies a little to the north of the centre of England, and so receives its westerly (chief rain-bearing) winds as follows.

The north-west wind arrives directly from the sea, with no outside intervening heights to break its force or abstract its rain. The west wind is also a direct sea wind for the extreme north of the county, but for the greater part of its surface comes across the mountains of Wales. The south-west wind, for the entire county, has crossed the Welsh mountains. Of these winds the south-west is the commonest, and the wind which most often blows as gales. Next in frequency, and in gale-frequency, is the north-west. At Buxton the west and south-west winds are rainier than the north-west.

### Natural Divisions of the County.

The geological formations of Derbyshire divide it naturally into three great areas, indicated on the accompanying sketch-map, and these areas differ conspicuously in respect of altitude, configuration, and rainfall. They comprise:

1. A north-western area, of high ground, highest in the north (where it culminates in the Peak—2,083 feet high), having a main plateau running nearly north and south, mostly over 1,000 feet in altitude, the whole area presenting pronounced contrasts of exposure and shelter. It has

a rainfall of from over 40 inches in the north (50 inches at Buxton) to 35 inches in the south. The subsoils are mainly millstone grit, carboniferous limestone, and carboniferous limestone shale, but there is a patch of coalmeasures at the extreme north-west.

2. A north-eastern area, of much lower altitude, with an undulating surface, which slopes from west to east and from north to south, with much less decided shelters (so much so, indeed, that the assessment of some of them is doubtful), having a considerably lower rainfall than the north-western area—namely, generally between 30 and 25 inches. The subsoil consists mostly of coalmeasures, but there is also a considerable stretch of magnesian limestone in the north-east.

3. A southern area, which contrasts strikingly with both of the former. Nearly all of it is relatively low-lying, much of it below 200 feet above sea-level, and a little of it along the Trent even under the 100 feet level. There is hardly any actual shelter, but all winds reaching it do so across much higher country. It has a low rainfall, mostly rather over 25 inches, but, along the north of the Trent valley, slightly under 25 inches. The area consists almost wholly of trias, a subsoil which former work by one of us showed to be associated with some of the lowest phthisis death rates in England. There is some alluvium along the Trent, a small patch of millstone grit at Melbourne, and a larger patch of coalmeasures in the south-east.

#### The Elimination of Subsoil as a Conflicting Influence.

To judge fairly, therefore, of the relations of phthisis and rain-bearing winds we must disentangle the influence of subsoil. This can easily be done by considering the effect of the rain-bearing winds over each geological formation separately. The same procedure also eliminates the influence of differences of rainfall and exposure; for millstone grit and the carboniferous limestone series (formations upon which phthisis mortality in England is relatively high) have here the heaviest rainfall, and the most pronounced exposure; whilst trias (on which phthisis prevalence in England is relatively low) has here the lowest rainfall and lies in a sort of hollow. The coalmeasures have been divided by us into north and south, on account of the different heights and rainfalls; we do not think that grouping the very small patch of north-western coalmeasures with the large area of north-eastern can lead to any error. The trias and coalmeasures of the southern area are considered separately. Melbourne, the only millstone grit locality in the south, must be taken with millstone grit generally, as it must not be confused with localities on the contrasting soil of trias. Most of the cases on alluvium are in the southern area; the exceptions are only a little to the north of it under very slightly heavier rains; they may therefore fairly be considered together.

We have satisfied ourselves that no other conflicting influences exist.

#### Results.

Taking, then, the effect of these winds over each subsoil separately, we reach the striking results shown in the following tables.

SUMMARY I.  
Percentages of Mortalities on Different Subsoils.

	(1) All Cases.		(2) All Deaths, but only Positive A and L Cases.	
	Sheltered.	Exposed.	Sheltered.	Exposed.
Millstone grit ... ..	3.45	21.10	5.0	30.80
Carboniferous limestone series	8.33	33.33	16.0	50.0
Northern coalmeasures ...	13.65	16.06	27.27	43.34
Magnesian limestone ...	0	25.0	No cases	No cases
Trias ... ..	No cases	9.10	"	17.66
Southern coalmeasures ...	"	4.35	"	5.56
Alluvium ... ..	"	5.55	"	12.50

Note.—Throughout these tables A=arrested; L=living, but not arrested and D=dead, certified from phthisis.

SUMMARY II.  
Percentages of Arrests on Different Subsoils.

	(1) All Cases.		(2) All Deaths, but only Positive A and L Cases.	
	Sheltered.	Exposed.	Sheltered.	Exposed.
Millstone grit ... ..	82.76	36.84	80.0	30.8
Carboniferous limestone series	58.34	33.33	52.0	16.7
Northern coalmeasures ...	68.15	65.42	45.46	33.33
Magnesian limestone ...	66.64	62.50	No cases	No cases
Trias ... ..	No cases	69.7	"	41.17
Southern coalmeasures ...	"	73.50	"	72.22
Alluvium ... ..	"	77.78	"	50.0

SUMMARY III.  
Totals.

Percentages ... ..	61.39	24.55	14.05	41.49	29.79	28.72

Thus in Derbyshire, as in Devonshire and West Shropshire, there is a remarkable body of evidence showing that patients with early phthisis die more often and recover more rarely when residing in exposure to strong prevalent rain-bearing winds than when residing in shelter from them, and this to a degree which cannot be considered negligible.

It is obviously important that phthisis sanatoriums should be located in shelter from these winds, and even more important that phthisis patients, on leaving their sanatoriums, should be advised to reside for some years in such shelter.

## ON IRRADIATED ERGOSTEROL AS A DRESSING FOR WOUNDS:

WITH SUGGESTIONS AS TO ITS MODE OF ACTION.

BY

C. J. BOND, C.M.G., F.R.C.S.,

HONORARY CONSULTING SURGEON, LEICESTER ROYAL INFIRMARY.

AN inquiry undertaken four years ago into the effect exercised by irradiated and non-irradiated cholesterol and some other unsaturated fatty substances on the cellular constituents of the blood (recorded in a communication to the Physiological Section of the British Association last September) had previously demonstrated the fact that blood incubated in a closed cell on a film of cholesterol crystals deposited from ether on a slide showed increased leucocytic activity and also agglutination, followed by haemolysis of the red cells, and that these changes were much more marked in the irradiated than in the non-irradiated film. It was this fact which led to the use of cholesterol, dissolved to saturation point (about 3½ per cent.) in liquid paraffin, as a dressing for ulcers and granulating wounds.

In 1925 a very extensive wound of the upper limb, in which, as the result of a machine strap accident, the entire skin surrounding the elbow had been stripped from the limb, and in which two unsuccessful attempts at autogenous skin grafting had been previously made, was dressed daily for some weeks with this cholesterol paraffin mixture, and later, when the sloughs had separated and granulations began to appear, the surface of the wound was irradiated through the cholesterol paraffin coating every other day with the ultra-violet rays from a mercury vapour lamp. After nearly six months of this treatment the wound eventually healed without cicatricial contraction, and the lad recovered with a functionally useful arm.

Following the discovery by Rosenheim and Webster in England, and Windaus and Hess in Germany, that irradiated ergosterol contained a much higher content of antirachitic or vitamin D substance than irradiated cholesterol, irradiated ergosterol, dissolved in the same way in liquid paraffin, was used in the place of the cholesterol as a dressing for varicose ulcers and for infected and granulating wounds. Good results were obtained both in the reduction of infection and in the promotion of healing.

Latterly "radiostol" in oil, diluted with liquid paraffin and soaked in gauze, has been found to be a convenient form of dressing. In two cases in which healing had been delayed by *B. pyocyaneus* infection it was noticed that the infective process was arrested in the part of the wound in contact with the irradiated ergosterol dressing, although it was still present in the area dressed by liquid paraffin, used as a control.

These observations showed that irradiated ergosterol so applied to wounds not only reduces infection and promotes healthy granulations; it also stimulates the ingrowth of epithelial cells from the margin, and so favours the healing process.

Experiments have also been carried out to test the bactericidal effect of irradiated as compared with non-irradiated ergosterol. Films of ergosterol were spread on the under surface of glass slips, some of which were irradiated and the remainder used as controls. The irradiated and the non-irradiated films were then inoculated with a suspension of *Staphylococcus aureus* in normal saline and placed film downwards on agar or blood serum

jelly, and incubated in Petri dishes. The colonies were found to be more numerous and larger on the non-irradiated than on the irradiated films.

These experiments require, however, to be repeated with other types of organisms, both aerobic and anaerobic.

### Mode of Action.

The first suggestion I wish to make is that the beneficial effect of irradiated ergosterol, when used in solution in liquid paraffin as a dressing for wounds, may be due to a further continued irradiation effect on the wound tissues after the primary irradiation of the sterol by the ultra-violet rays from the mercury vapour lamp has ceased. The question of the physical and chemical action of the irradiated substance still remains.

In the BRITISH MEDICAL JOURNAL of October 8th, 1927 (p. 637), I described a colour test for distinguishing irradiated from non-irradiated ergosterol, which depends on the oxidation of potassium iodide by liberated oxygen, and the formation of a pink or a blue coloured iodide of starch when a solution of boiled starch dissolved in potassium iodide solution is applied to such an irradiated film. This and similar colour tests with ammonium ferrous sulphate and potassium thiocyanate solutions, and the haemolytic effect of the irradiated sterol on a suspension of washed red cells previously described, and the fact that ergosterol can be activated by ozonized air, all suggest that the taking up of oxygen during irradiation and the subsequent liberation of the oxygen may be the mechanism by which the irradiated sterol acts upon the blood and tissue cells and epithelial cells in the wound.

According, however, to Rosenheim and Webster (*Lancet*, September 17th, 1927) the conversion of ergosterol and the formation of vitamin D is brought about equally well in an atmosphere of nitrogen, the supposition perhaps being that the change consists in a molecular rearrangement only.

Experiments carried out by myself, in which thinly spread ergosterol films were irradiated through water covering the film, and also with films spread on the under surface of quartz slips, placed film downwards on mercury, and then irradiated through the quartz (atmospheric oxygen being thus excluded), showed that no activated substance had been formed capable of liberating iodine when tested by the starch potassium iodide and other colour tests.

These and other observations suggest the conclusion, either that ergosterol when treated by ultra-violet radiation takes up oxygen which can be subsequently liberated and is itself vitamin D, or that two substances are formed from the sterol during radiation—one a vitamin, which does not take up and subsequently liberate oxygen, and the other a substance of a peroxide character, which does take up oxygen and gives the starch potassium iodide colour reaction, and which haemolyses the red cells. If two substances are formed then the further question arises which of these substances exercises the stimulating and healing effect on wounds.

The fact that the activated substance which forms during irradiation is a fat-soluble material is of considerable importance; for, unlike a water-soluble material, a fat-soluble substance can transmit oxygen through the lipid coatings of the cell and its nucleus, and if it is also an oxygen carrier, soluble in fats, it may exert its influence on red cells, leucocytes, and tissue cells in the way described.

In support of this view it is interesting to find that when large and well-formed crystals of ergosterol, deposited slowly from solution in tetrachlorethane (Westron) on a slide, are viewed with polarized light after irradiation only the very small crystals become completely isotropic or non-polarizing. The larger crystals still contain a luminous core surrounded by a non-luminous non-polarizing layer of resinous material, which appears to protect the central core from further change.

If we assume that only one fat-soluble oxygen-absorbing and oxygen-discharging substance is formed during irradiation, then such an assumption seems also to imply that it is in virtue of this fat-soluble character, in conjunction with its capacity for liberating oxygen, that vitamin D exerts

its physiological effect on both general and local metabolism.

The further fact that irradiated ergosterol ("radiostol") after long exposure to atmospheric oxygen (especially in a warm temperature) is found to lose its antirachitic value, and also its capacity for liberating oxygen, and no longer oxidizes potassium iodide, as shown by the starch test, is also important. It may perhaps be explained on the assumption that the oxygen additive compound undergoes rearrangement, in consequence of which the oxygen is no longer easily liberated, the final product being the inactive resinous material.

My object in putting forward these suggestions is, first, to point out the value of certain irradiated sterols when used as a dressing for wounds, and secondly, to indicate certain directions in which, as it seems to me, further research would be very useful in throwing light on the mode of action of vitamin D.

Put shortly, the present position is this: we know from the brilliant work of a number of observers that irradiation will convert ergosterol and other unsaturated sterols into a substance having antirachitic qualities—that is, vitamin D. We have now shown that irradiation will also produce from the ergosterol a fat-soluble substance containing oxygen, some portion of which can be readily liberated. We also know that ozonization (and possibly other methods) will convert ergosterol into an oxidizing substance, but we do not yet know whether ozonization will produce an antirachitic substance. Neither do we yet know whether the vitamin D and the oxidizing substance are one and the same thing.

## AUTOGENOUS RESIDUAL VACCINES:

THE THERAPEUTIC RESULTS OBTAINED IN A SERIES  
OF 360 CASES.

BY

C. E. JENKINS,

PATHOLOGIST TO SALFORD ROYAL HOSPITAL.

THE method of preparation of these vaccines was described in this JOURNAL six years ago. On that occasion the results obtained by the treatment of cases of chronic bronchitis in the out-patient department of Salford Royal Hospital were presented and compared with cases treated by a similar stock vaccine prepared according to the older and usual method. The conclusion was drawn that the residual vaccine was superior.<sup>1</sup>

The original technique for the preparation of residual vaccines has been slightly modified. One washing, combined with the use of hydrogen peroxide as introduced by Deau,<sup>2</sup> is found to be sufficient. This paper contains the results obtained when autogenous vaccines are used, and the whole of the cases now described were treated with that type of vaccine.

Detailed comment is best made under the separate group headings, but it is necessary to draw particular attention to the means employed for assessing the benefit or otherwise of the treatment. Almost without exception the result has been assessed by some other medical practitioner, usually the patient's private doctor. A minority of the records were upon hospital case sheets, and where I have been compelled to pass an opinion upon them myself I have classed as successful only those cases which showed a marked improvement obviously related to the administration of the vaccine; cases which showed a slight improvement or no change are failures, and those cases which, from inadequacy of notes or some other reason, showed an obvious benefit not attributable with certainty to the vaccine therapy, are classed as "Not traceable." Cases which slowly improved after vaccine therapy had ceased a month or so previously are deemed to be failures. The remainder of the untraced cases are so owing to disappearance of the patient or to my failure to establish contact with the patient's doctor.

It will be seen that the standard of assessment is of a simple order—succeeded or failed. Obviously such a classifi-

cation must be considered in relation to the disease. Thus the successful treatment of furunculosis means a complete and lasting cure. On the other hand, an advanced case of rheumatoid arthritis cannot be expected to yield so completely to vaccine therapy that all bony deformity disappears; in this case one looks for freedom from pain, disappearance of the swelling of the soft tissues, increased mobility of the affected joints, cessation of periodical acute attacks, and the patient's restoration to a more active life. An early case may be expected to clear up completely. Every case, however, is susceptible to analysis by means of a simple question—Was the vaccine therapy really worth while considering the results and the nature of the case?

I wish to offer my thanks to all the medical practitioners whose time I have taken up and whose memories I have racked in my efforts to assemble these records.

The results now published comprise all the autogenous residual vaccines made between January 1st, 1924, and December 31st, 1926.

Total vaccines prepared ... ..	448
Results not traceable ... ..	53
Still under observation ... ..	35
Results now recorded ... ..	360

The cases still under observation will be mainly, but not necessarily, the most recent. A vaccine for chronic nasal catarrh requires some time before its result is apparent so far as prophylaxis is concerned, whereas the result to be obtained in a case of rheumatoid arthritis may, and frequently does, declare itself after two doses.

It will be convenient to consider the results in seven groups.

### GROUP A.

Disease.	Total Cases.	Success.	Failure.	Percentage of Success.
Furunculosis ... ..	45	40	5	88.9
Pyogenic abscess ... ..	4	4	0	—
Sycosis ... ..	3	2	1	—
Total of group ... ..	52	46	6	88.5

The failures in furunculosis include a diabetic who refused to limit his diet in any way, and a patient in whom a large carbuncle had already spread to the cord and produced myelitis when I first saw him. The three cases of sycosis barbae show two-thirds of successful results, which is probably unduly flattering.

### GROUP B.

Disease.	Total Cases.	Success.	Failure.	Percentage of Success.
Rheumatism and rheumatoid affections ... ..	63	50	13	79.3
Gonococcal arthritis ... ..	3	3	0	—
Total of group ... ..	66	53	13	80.3

In the gonococcal cases the organism was isolated in pure culture from the affected joint. The rheumatic group require explanation and comment. Before a vaccine is prepared a preliminary bacteriological examination is always undertaken. Cultures are made from the throat and faeces as a routine. When pyorrhoea or some other suppurative lesion is present the appropriate cultures are made. The predominating organism I have found to be a streptococcus—*haemolyticus*, *salivarius*, or *faecalis*—or the enterococcus. I have never seen anything to suggest that these streptococci concerned in the rheumatoid group are in any way different from the standard types of these varieties; it is, of course, quite possible that in a susceptible case certain strains do produce toxins which have rather more affinity than usual for the joints and heart valves.

The majority of the vaccines in this group were made from the faeces, and an arbitrary standard of suitability

for vaccine treatment is therefore necessary. The normal proportion of streptococci and enterococci in the faeces is from nil to 2 per cent.; a vaccine is not prepared unless the proportion is greater than 20 per cent. A pure culture is not uncommon. Two specimens separated by a twenty-four-hour interval are obtained, as it is found that the proportion is apt to vary a little from day to day. The standard medium for all routine examinations in the Salford laboratory is nutrient beef broth agar containing 2 per cent. of ox serum. It is possible that a higher percentage of streptococci is thus found than would be the case on "plain" nutrient agar, which is never used.

Other organisms that have been found in the faeces in high proportions and which have given satisfactory results in an autogenous vaccine—and therefore presumably have a causal relationship to the disease—are *Staphylococcus aureus*, *B. lactis aerogenes*, Friedländer's bacillus, *B. proteus vulgaris*, and various diphtheroid bacilli. Approximately one-half of the rheumatoid cases examined show these bacterial abnormalities or foci of infection. Where no abnormality is found a vaccine is not administered, and the results of stock vaccines in such cases have not been impressive. This probably explains why the vaccine treatment of the rheumatoid diseases is the subject of such conflicting opinions. The cases for which a vaccine is proposed must be bacteriologically examined first.

GROUP C.

Disease.	Total Cases.	Success.	Failure.	Percentage of Success.
Intestinal toxæmia ... ..	21	16	5	76.2
Erythema and urticaria ...	12	9	3	75.0
Mucous colitis ... ..	4	2	2	—
Total of group ... ..	37	27	10	73.0

The cases of intestinal toxæmia are a mixed group that showed wide variations of blood pressure, vague skin eruptions, dyspepsia and diarrhoea, anaemia, and in a few instances a mental complex that had been dismissed by various observers as neurasthenia. The improvement in these cases was frequently dramatic. It may be thought that the results obtained were largely produced by suggestion, but several of the patients had had treatment far more spectacular than a bottle of vaccine, and it is difficult to see how suggestion could cure anaemia.

The second section in this group comprises cases which were found to have an infection, usually in the bowel or throat. Where no bacterial abnormality was found a vaccine was not prepared, and about two-thirds of the cases sent for examination were rejected on this ground as being unsuitable for vaccine therapy.

The organisms isolated were varied, and no one organism seemed specially prominent as a cause. The bacteria found comprised *B. lactis aerogenes*, *B. acidilactici*, *B. diffluentis*, *B. proteus vulgaris*, *B. coli communis*, Morgan's bacillus, streptococci, and *Staphylococcus aureus*.

GROUP D.

Disease.	Total Cases.	Success.	Failure.	Percentage of Success.
Cystitis ... ..	33	27	6	81.8
Pyelitis, pyonephrosis, and pyelonephritis ...	13	9	4	69.2
Vaginitis (not venereal) ...	3	2	1	—
Total of group ... ..	49	38	11	77.5

The remote results of treatment of this group appear to depend upon the age and sex of the patient. Young women and most men remain clear when they have once been cured, but middle-aged and elderly women, particularly if married, show a decided tendency to relapse after

about two years' freedom from trouble. A further course of vaccine treatment will put them right again for another period of about the same length.

GROUP E.

Disease.	Total Cases.	Success.	Failure.	Percentage of Success.
Sepsicæmia ... ..	2	1	1	—
Pyæmia ... ..	1	0	1	—
Osteomyelitis ... ..	3	2	1	—
Chronic cellulitis ... ..	2	1	1	—
Erysipelas ... ..	1	1	0	—
Ulcerative endocarditis ...	1	0	1	—
Total of group ... ..	10	5	5	50

The only inference that one can extract from the above figures seems to be the folly of waiting for an autogenous vaccine when a stock one, ready on the spot, could have been given several days earlier for a set of conditions in which time is all-important. It is probable that better results would have been obtained by the use of one of the two special types of stock residual vaccine, designed for the purpose, and given the moment the condition was diagnosed or even suspected. They could have done no possible harm.

GROUP F.

Disease.	Total Cases.	Success.	Failure.	Percentage of Success.
Chronic and recurrent acute catarrh of the respiratory passages, including bronchitis	101	92	9	91.1
Asthma accompanied by bronchitis	15	12	3	80.0
Ulcerative tonsillitis and "septic throats"	10	8	2	80.0
Localized infections of nasal sinuses and antra	6	4	2	—
Total of group ... ..	132	116	16	88.0

The first section of this group is the largest and the most satisfactory in its results. The average period of protection given by the vaccine is about two years—two complete winters. All the usual causal organisms have been found; the only point of interest is the connexion of the pneumococcus with a certain type of catarrh. In the course of routine work it has been observed that cases of nasal catarrh with a blood-stained discharge or a tendency to catarrhal deafness are more commonly associated with the pneumococcus than with any other organism. At the same time, the association is not as complete as that between bronchitic asthma and the streptococcus.

The asthma cases were interesting inasmuch as they showed the clearest division of the disease into two types—the purely "neurotic" and the type in which the asthma is secondary to chronic bronchitis; that is, asthmatic attacks occur only during or immediately after an attack of the former disease. The organism invariably present is a streptococcus, usually of the *salicarius* variety. It is customary to find this organism forming at least 95 per cent. of the total organisms present in the sputum. A pure culture is not remarkable.

It will be seen that the results of treatment of bronchitic asthma are gratifying. On the few occasions when I have been persuaded to supply a stock streptococcal vaccine for a patient suffering from the other type of asthma I have never seen any result that could be called successful. The benefit in the bronchitic type cannot be due to the action of a non-specific protein. If it were so, the vaccine should benefit both types indifferently. A survey of the facts indicates that the role of the streptococcus could hardly be more specific.

## GROUP G.

Disease.	Total Cases.	Success.	Failure.	Percentage of Success.
Pyorrhoea ... ..	2	2	0	—
Chronic septic ulceration ...	2	1	1	—
Suppurating sinuses (not tuberculous)	3	2	1	—
Septic thrombo-phlebitis ...	1	1	0	—
Hepatic abscess (not amoebic)	1	0	1	—
Aene vulgaris ... ..	3	2	1	—
Unna's ulcerating inguinal granuloma due to <i>B. pyocyaneus</i>	1	0	1	—
Total of group ... ..	13	8	5	61.5

This last group does not call for comment at length. The two cases of pyorrhoea were similar—young women who wished to save their own teeth. Pyorrhoea cases associated with rheumatism are placed in Group B.

## Grand Total of all Cases.

Total cases ... ..	360
Success ... ..	294
Failure ... ..	66
Percentage of success ... ..	81.5

## CONCLUSION.

I would again draw attention to the fact that the benefit in the vast majority of these cases has been appraised by independent observers, which fact is rendered doubly important by the nature of the results. The high proportion of success obtained is attributable to two factors. In the first place, selection of suitable cases by bacteriological examination provides one with clinical material that offers a rational basis for the use of vaccine therapy. The results are influenced accordingly. The second factor is the residual vaccine itself, which has an inherent therapeutic efficiency greatly superior to that of the older "whole" type of vaccine.

In recent years the production of improved types of antigens has engaged the attention of a number of workers. The most recent paper on the subject is by Arkwright,<sup>3</sup> and deals with typhoid and paratyphoid vaccines. Amongst other facts elucidated he shows that a heat-stable antigen is more efficient than a heat-labile one obtained from the same organism, and notes the interesting detail that a heat-stable antigen that had been heated to 100° C. gave slightly better results than the identical antigen unheated. Precisely the same result is revealed in the tables published in my original paper on residual vaccines.

Holder and Ferry<sup>4</sup> have produced antigens that differ in the mode of preparation, and almost certainly in their composition, from those of Arkwright and myself. At first sight such results may appear contradictory, but that is not necessarily so. The improvement upon heating the heat-stable antigens can be explained in one of two ways. It may be supposed that the antigen itself is actually improved by heating, which is improbable. The alternative is more feasible: it is that some substance inimical to antibody formation is destroyed by the heat.

The aggressins have not received much attention in recent bacteriological studies, but it has been shown by Bail and subsequent workers that their action is to paralyse the tissue resistance against bacterial invasion, although the aggressins themselves are not toxic, and that immunity can be created against aggressins or against bacteria. When a mixture of bacteria and their aggressins is administered the host experiences increased difficulty in the production of an adequate resistance.

This experimental evidence indicates two methods of producing immunity, and it is conceivable that the immunogens of Holder and Ferry depend in part at least for their efficiency upon the small quantities of aggressin present in the washings. The heat-stable antigens are probably freed from their aggressins when heated, and are therefore capable of stimulating to the fullest extent the resistance appropriate to them.

If this conception of the action of these different bacterial substances be correct, it follows that a mixture of bacteria and their aggressins, such as is represented by an ordinary "whole" vaccine, cannot be as efficient as some of the fractional types of vaccine. Further experience with many of these fractions may show that they are not in opposition to each other as potential remedies, but will perhaps be used most effectively at different stages of the same disease.

## HAIR-BALLS IN THE ALIMENTARY TRACT:

WITH THE  
RECORD OF A CASE OF INTESTINAL OBSTRUCTION DUE TO  
FOUR HAIR-BALLS.

BY

CHARLES NOON, F.R.C.S.,

ASSISTANT SURGEON, NORFOLK AND NORWICH HOSPITAL.

HAIR-BALLS occurring in the gastro-intestinal tract are not often met with. When found the stomach is the commonest situation for their development, but they may be rarely present in any part of the intestinal tract. The literature contains a few accounts of masses of hair situated in the ileum giving rise to intestinal obstruction, of which the case here recorded is an example.

A woman, aged 30, was admitted to the Norfolk and Norwich Hospital on October 15th, 1925, complaining of abdominal pain. She was married at the age of 24, and had one child, aged 4 years. She had been in good health up to December, 1924, when, on visiting her husband's relatives, she became strange in her manner and difficult to manage. Her mental condition became worse, and she was admitted to the Norfolk County Mental Hospital on January 5th, 1925. On admission her condition was diagnosed as recent mania.

From January to June, 1925, she was difficult to manage, irritable, and destructive. She then began to improve mentally, but at the same time her physical condition deteriorated; she rapidly lost weight, and suffered from constipation, followed by diarrhoea, abdominal pain, and distension. The stools became very offensive. On October 15th, 1925, she was discharged from the mental hospital, and the same day was admitted to the Norfolk and Norwich Hospital.

## Condition on Admission.

The patient was a tall, pale, emaciated woman. Her mental condition was fairly good; she could answer questions intelligently, although she was very ill and in pain. Temperature 99°, pulse 100, respirations 18. The tongue was furred and the breath foul. There was no evidence of any disease of the lungs. The abdominal wall was very thin and the abdomen distended, especially below the umbilicus. There was tenderness all over the abdomen. A fairly well defined swelling could be felt in the region of the caecum. Its surface was smooth and its margins clearly outlined. It was irregular in shape, and measured about 3 by 4 inches. It was painful to touch. The rectum was ballooned, and a bimanual examination was impossible because of the pain and tenderness. The diagnosis of chronic intestinal obstruction was made, owing to the swelling felt in the abdomen being possibly of inflammatory nature arising in connexion with the appendix.

An exploratory operation was advised and performed soon after admission to hospital.

## First Operation.

The abdomen was opened by a mid-line incision below the navel. The lower part of the ileum was found to be much distended, red, and inflamed, and one loop was adherent in the pelvis. On freeing this a small perforation in the intestine was visible. The caecum and the lower part of the ileum were drawn out of the abdomen and packed off. The wall of the lower two feet of the ileum was found to be much thickened, and its lumen contained soft bodies which could be separated one from another. The small bodies which could be separated one from another. The small perforation in the bowel was examined, and a piece of hair was seen projecting through it. The intestine was then opened, and very extensive ulceration of the mucous membrane of the intestine. A large collection of offensive fluid was removed by irrigation, and the intestine drained by a rubber tube stitched in place by Witzel's method. The intestine was then stitched to the abdominal wall.

After the operation the patient's mental condition deteriorated for a time and she was difficult to manage, but she gradually improved, both mentally and physically. The enterostomy worked satisfactorily, although it was difficult to keep the skin of the abdominal wall round the opening free from superficial ulceration. From time to time the patient passed motions by the rectum naturally.

## Second Operation.

On December 10th, 1925, two months after the first operation, it was decided to close the opening in the small intestine by a second operation. This was done by resecting 8 inches of small

intestine and joining the intestine by an end-to-end anastomosis. The patient made a good recovery from this second operation. She improved rapidly, and six weeks later was discharged from hospital. She has been heard from frequently since, and is now enjoying good health.

In 1779 Bandamant described the first reported case of hair-ball; since then over 100 cases have been recorded. The condition is frequently found in animals in the season when the hair is shed, but rarely gives rise to symptoms, as the hair-balls are usually expelled by vomiting or passed in the faeces. In human beings the hair-eating habit is generally confined to young females, occurring usually in individuals of nervous constitution with perverted appetites, or in patients who have definitely exhibited symptoms of insanity.

Hair-balls may be multiple or single; those developing in the stomach are usually single. The hair is gradually worked up into a mass by the gastric movements until at length it entirely fills the organ and forms a cast of the stomach, with a prolongation in some cases through the pylorus into the duodenum. In the small intestine, in which they are very rare, the hair-balls are not infrequently multiple; they take the shape of the intestinal tube, and may be, when closely pressed together, faceted.

The clinical symptoms caused by the presence of a hair-ball in the gastro-intestinal tract depend on its position, its size, and the development of obstructive and inflammatory conditions to which it may give rise. Ledra-Henzl states that the stomach is exceptionally tolerant of foreign bodies, but eventually rebels when the limit is reached. Ultimately symptoms appear, such as pain, vomiting, and attacks of diarrhoea alternating with constipation, and there is much wasting. The breath becomes foul, and the stools are offensive. In the case here recorded these typical symptoms were present. The development of obstinate constipation was first noticed; this was followed by occasional vomiting; later on the constipation alternated with attacks of diarrhoea. There was marked wasting, and an abdominal tumour was discovered. It has been alleged that the patient's hair may be deficient in the frontal region, but this is unusual in cases in which hair-balls are found in the stomach. In cases in which complications have not developed a marked feature is the very slight disturbance of nutrition. In the rare cases in which hair-balls have been found in the intestine the lower part of the ileum is the site where they have usually lodged.

The clinical picture presented has usually been one of chronic intestinal obstruction associated with wasting, abdominal distension, and vomiting; in addition, an abdominal tumour is usually present. As the hair-ball usually occupies the stomach the tumour, when present, is generally situated in the epigastric region, and may extend from one hypochondrium to the other. Its outline is well defined, and its surface is smooth and hard. It is usually movable. These were the characteristics in this case, with the exception that the tumour was situated in the right iliac fossa and reached to the mid-line of the abdomen. Occasionally the sensation of crackling, or deep-seated crepitation, is made out on palpating the swelling.

The x-ray appearances of hair-balls in the stomach have been carefully studied and described by Thurstan Holland. It has been observed that the first mouthful of an opaque meal spreads out to form a cap over the upper end of the tumour. The shape of the tumour is very characteristic when covered by the opaque meal.

#### Treatment.

The treatment consists in removing the foreign body by operation. A carefully thought-out technique is necessary during the removal of the hair-ball as the discharges surrounding the mass are often foul and septic. In the case here recorded it was necessary to drain the intestine for a considerable time. A second operation was performed later to close the faecal leak, and this necessitated resection of a segment of small intestine, about 8 inches in length, and an end-to-end anastomosis.

## THE SCOPE OF SURGERY IN THE TREATMENT OF CHRONIC RHEUMATOID AND OSTEO-ARTHRITIS.\*

BY

C. MAX PAGE, M.S., F.R.C.S.,  
SURGEON TO ST. THOMAS'S HOSPITAL.

COMMUNICATIONS on the treatment of chronic rheumatoid infections may almost be regarded as chestnuts in the programmes of medical societies. I take it that this tendency to discuss the various problems connected with these diseases is an index of our failure to arrive at any generally accepted solution of them. The subject is certainly one of exasperating complexity, and the average late results of the more severe examples of rheumatoid arthritis may well discourage the most optimistic of clinicians. The issue on this occasion is, at any rate, clearly defined, being limited to the surgical aspect. I shall not attempt or consider any classification beyond that in the title, nor do I propose to consider the surgical treatment of what may be the primary focus of infection. I think the simple subdivision is sufficient to guide us in radical local treatment, and the surgery of the presumed primary focus would carry us too far afield.

For the purposes of surgical treatment it will, I think, be sufficient to accept the chronic rheumatoid group as including several infective conditions, the results of which on individual joints may vary within wide limits. This statement is as true of the late results in individual joints as of the earlier clinical course. In the late stages of joint change, due to what has been called rheumatoid arthritis, we may meet with extreme capsular fibrosis associated with varying degrees of destruction of the articular cartilage. Ankylosis may be fibrous or bony.

Osteo-arthritis may be accepted as a change in a joint initiated locally by some biochemical reaction; the association with injury is no doubt in many cases an important factor in the production of the process, but it does not materially affect the question at issue in the treatment of the condition. The local changes may be clearly separated from the first-mentioned variety by the fact that ankylosis never occurs, although absorption of articular cartilage may be complete, and that periarticular fibrosis is never a prominent feature.

It must be admitted at the outset that both conservative and radical treatment of joint disease of the character under consideration can at the best ameliorate the condition, and seldom, if ever, restore the state to normal.

In chronic rheumatoid arthritis it is generally agreed that no drastic treatment to the joints can be applied while the infective process is still active, on account of the risk of producing a local or distant extension of the condition. A few authors have advocated synovectomy of several of the affected joints at an early stage; but I think there is little support for this method. Evidence of activity is given by the presence of fever and the signs of local inflammatory reaction about the joints. While this is present surgical treatment will be limited to the avoidance of contractures and to holding the parts affected in such a position that function will be interfered with as little as possible should ankylosis of the joint ensue. This is not a dramatic part of surgical treatment, but it is, none the less, a very important one, and one that is perhaps insufficiently recognized, if we are to judge by the serious and disabling deformities which come to hand for treatment in late stages. The reason for this is perhaps partly because the treatment of rheumatoid arthritis in the active period is considered a medical matter. The comfort of the patient is bound to influence the practitioner, and attitudes of maximum comfort or minimum discomfort assumed during periods of active inflammation of a joint may be progressively exaggerated till they lead to extreme flexural deformities. I do not propose to describe in detail what may be regarded as the ideal positions which should be maintained for all the important joints during an acute or subacute arthritis. They

\* Abstract of a paper introducing a discussion at the Medical Society of London on February 27th.

are well recognized and hold good for any process liable to leave a stiff joint. I should like to draw attention to a few deformities which are too commonly met with, and which can, as a rule, be avoided by suitable splintage or support. In the lower extremity an acute and painful effusion into the major joints will lead to the adoption of the flexed position of the thigh and knee in the first attempt to relieve pain. The hip-joint can be ankylosed in flexion to 20 or 30 degrees without interfering seriously with function, provided there is no adduction. Fixed flexion of the knee-joint beyond 5 or 10 degrees should be avoided. Extension in a Thomas's splint of a light weight without any splint will prevent this deformity being excessive.

In the upper extremity one of the most disabling deformities often seen after a polyarthritis is flexion at the wrist-joint. This joint can be kept straight or slightly extended in a light plaster casing, which leaves the fingers free without discomfort to the patient. The position of the shoulder and elbow should also be considered.

The next stage of polyarthritis in which surgical measures may apply is in the chronic phase. All signs of the infection should have died out, ankylosis or contractures are established, and the problem becomes essentially an orthopaedic one. It is not always easy to settle when this time has arrived, and it undoubtedly varies with the nature of the infection. It is most undesirable to operate if infection is still latent, and the matter may be tested by mobilizing a small joint under anaesthesia, and observing the local and general reaction. Operations undertaken at this stage will be of two types: first, to correct the disabling deformity, and secondly, to restore the movements in stiff joints. The two conditions may be dealt with at the same time in some cases.

In order to correct deformity one of three methods may be employed—namely (1) manipulation under anaesthesia, (2) graduated extension, (3) open operation.

1. Manipulation under anaesthesia is often sufficient to correct contracture of short standing. It is clearly valueless in those cases in which bony ankylosis has occurred. Against the use of the method it must be admitted that the procedure is more likely than anything else to light up any latent infection. I do not think, however, that this is sufficient reason to cut the method out. It should be approached with caution, and with due observance of the condition of the patient. In some cases it will not only correct a faulty position, but may restore a considerable degree of movement to a joint previously stiff.

2. Graduated extension may be employed on special joints, as the knee and hip, for similar purposes. It has the merit of involving no risk of causing a flare-up, but it must be admitted that it is not alone likely to be effective in those cases in which there has been much destruction of articular cartilage or fibrosis in and around the joint.

3. An operation designed only to correct position will be in the nature of an excision of the joint, coupled with the division of contracted capsular structures and even tendons in the neighbourhood. In some instances in which there is bony ankylosis a simple osteotomy may be sufficient. This operation is most often used for ankylosis of the hip-joint. It should, however, be noted that osteotomy is a delusive operation in those cases unless the ankylosis is sound. If it is only fibrous there will be a tendency for flexion and adduction to recur.

Operations undertaken to restore movement have not much vogue in relation to chronic rheumatoid arthritis, but in most instances in which ankylosis of several major joints has occurred it should be considered. There is no doubt that after many of these infections an arthroplasty, though it appears satisfactory in the first month or so, tends to stiffen up. The technique of the subject will be gone into further when considering the surgery of osteoarthritis.

The surgical problem in relation to the treatment of osteoarthritis is simpler. We are dealing here with a relatively common disease in which no question of any local bacterial infection arises. The chief difficulty is in the selection of cases suitable for surgical treatment. Pathological changes vary in degree in a remarkable way, and to an extent unexplained by any recognized etiological factor. Though the disease in its advanced form may be

practically monarticular, cases occur in which many joints are involved, and the problem then presented is not unlike that of chronic rheumatoid arthritis. The severity of pain experienced by the patient is usually the reason which decides him to seek radical treatment. Its degree is remarkably variable in its incidence, and bears no direct relation to the extent of the anatomical change. It would appear that it is the result of changes in the capsule of the joint, rather than in the articular surface. In view of the fact that bony ankylosis does not occur in this disease when it is allowed to run its natural course, freedom from pain cannot be assured at any stage.

The incidence and chronic nature of the disease naturally leads to a trial in sequence of conservative measures, such as drugs, vaccines, diet, baths, and various forms of physiotherapy. The search for focal infection and attempt to eradicate it must be regarded as essential in all early cases; I confess that in the late stages it does not appear to me to be of such crucial importance. In the early stages surgical measures will be limited to the provision of rest from weight-bearing for the affected joint. This is clearly of most importance in the lower extremity. The weight-relieving calliper or ambulatory splint will often be of service, and if properly fitted will certainly arrest the progression of the articular change.

Manipulation, as in the case of rheumatoid arthritis, is the simplest surgical procedure which can be applied. It aims at breaking down adhesions, or, rather, stretching fibrosed or capsular structures which limit movement or are the source of pain. When the disease is advanced and associated with gross osteophytic outgrowths, I do not think much good can be obtained by the method. In my experience the benefit received has generally proved only temporary in nature. I do not wish to suggest that the method should not be employed regularly. It is of striking value in early cases of chronic arthritis in the knee and shoulder in which the changes are mainly capsular.

When we come to the disease in its advanced form the direct indications for a radical operation may be clearly defined as two in number—namely (1) progressive deformity in relation to the joint affected, (2) persistent pain. These indications hold good whatever anatomical form the disease assumes, and whether the probable causative factor appears to be trauma, toxic absorption, or bacterial infection.

The character of the operation selected will be influenced by the number of joints involved and the life expectation of the patient. The operation may take the form of what may be termed (1) speculative arthrotomy, (2) an operation aiming at ankylosis, or (3) an arthroplasty, an operation planned to restore movement at the affected joint. The decisions as to which of these procedures is suited for any particular case must, as stated above, depend on several factors.

1. Speculative or exploratory arthrotomy has its most important field in the knee-joint. It will generally be undertaken in those cases in which there is pain without deformity, or recurrent attacks of effusion into the joint associated with symptoms of internal derangement. Good exposure of the joint is obtained by a vertical lateral excision; action is then taken in accordance with the state found. Loose bodies may be removed, pedunculated and hypertrophic villi may be excised, marginal osteophytes removed, or the articular cartilage trimmed or shaved where it appears diseased. In those cases of so-called "lipoma arborescens" a complete synovectomy may be carried out. The operation is a conservative one, and should not materially interfere with the subsequent normal range of movement at the joint; it does not involve a prolonged period of incapacity. In my experience the results are often much better than would be expected from the limited nature of the operation. I do not know whether such results are to be attributed to the mechanical measures adopted or to the period of rest and careful after-treatment usually involved.

2. Arthrodesis, if effectively attained, clearly is the most radical and final operation; it cures the pain for good and all, its only drawback being the mechanical disability entailed by the stiff joint. I am inclined to think that it is the operation of choice in the hip-joint in a patient with

a good expectation of life, provided that the disease is monarticular. It is generally accepted as being the most effective procedure when the knee is seriously involved, and when deformity is developing in relation to that joint. In many cases the operation undertaken to secure bony ankylosis may fail to produce this, leaving in some cases fibrous ankylosis, and in others a false joint. This failure to secure bony union does not seriously prejudice the result in the upper extremity, and even in the lower pain will be relieved by the measure, though some deformity or contracture may develop. Failure to secure bony ankylosis results from either an incomplete operation or inadequate or insufficient fixation afterwards.

3. Formal arthroplasty, or operations designed to leave a movable joint, are naturally in favour if they are effective in curing symptoms and in giving a sufficiently stable joint. In the case of the metatarso-phalangeal joint of the great toe an operation of this character is carried out as a routine by many surgeons for conditions of hallux rigidus or valgus. The good results obtained in this operation cannot, however, be employed as an argument in favour of a similar procedure for the major weight-bearing joints, the knee and the hip. In these articulations it is clear that there is risk of the new-formed joint undergoing in course of time the same pathological changes that were responsible for the primary condition. This risk is so definite in the case of the knee that I think an arthroplasty should only be aimed at here in exceptional circumstances. In the hip-joint operations aiming at mobility appear to be coming more into vogue, being generally based on Whitman's method of reconstruction. Membrane or fascia, after the method of Baer or Putti, is often interposed to secure a movable joint. My own view is that the operation should be limited to the elderly and to those cases in which, on account of disease in the opposite hip or of other joints in the same extremity, mobility is particularly important in order to secure reasonably good function.

This survey represents a brief sketch of a complicated problem. It will be noticed that I have not referred in detail to the treatment of osteo-arthritis of the spine and sacro-iliac joints; this has not been done because the technical methods employed in these areas must still be regarded as on trial. I have not entered into the surgical technique of the different methods discussed, as a full account of these can be found in the literature. My aim has been to indicate the importance of surgical supervision from an early stage in all cases of chronic arthritis, and to demonstrate the possibilities of radical treatment of the more advanced forms.

## CONGENITAL DISLOCATION OF THE HIP: A METHOD OF CONTROLLING THE PELVIS DURING REDUCTION.

BY

F. WILSON STUART, M.Ch.,

SURGEON TO BIRMINGHAM CRIPPLES' UNION AND ROYAL ORTHOPAEDIC AND SPINAL HOSPITAL (AMALGAMATED), AND TO MANTFIELD ORTHOPAEDIC HOSPITAL, NORTHAMPTON.

To every orthopaedic surgeon with experience of a considerable number of cases of congenital dislocation of the hip-joint in patients of varying ages it must be apparent how inadequately control of the pelvis can be carried out by an assistant during attempts at reduction. The chief reason for this is that in pressing downwards on the opposite side of the pelvis in an attempt to fix it, the assistant is converting the pelvis into a short-armed lever, the effect of which, when pressed down, is to raise up the opposite side of the pelvis from the table, carrying the vacant acetabulum with it. The manipulator is at the end of the long-armed lever—namely, the knee of the dislocated femur—and his efforts to lever the head over the posterior lip of the acetabulum are really aiding the assistant in raising the pelvis from the table, and therefore a great deal of energy is wasted as the result of their applied forces acting in the same direction.

This action of opposing levers is very evident when dealing with the older cases—patients aged 5 years and upwards.

Some time ago I was faced with the problem of reducing a case of bilateral dislocation in a child aged 6, big for her age, muscular, and with strong femora. The femoral heads were unusually high above the acetabula. An attempt to reduce the left hip failed completely and was abandoned till a future date, after a considerable range of telescopic movement had been obtained by alternate extension and relaxation. Meanwhile both hips were to be subjected to daily stretching.

A fortnight or so later a second attempt was about to be abandoned when, on considering ways and means, it occurred to me to make use of the roller towel which had been employed for counter-extension purposes, and, passing the left limb through one loop, the two strands were crossed on themselves and continued over both anterior superior iliac spines, being well spread out so as to cover the whole pelvic front: the assistant put his foot in the other loop as it hung down towards the floor. A triangular block was then placed between the pelvis and the great trochanter, against which the towel passed. This enabled me at once to apply extension at the femoral condyles with both hands, the limb being in the abducted position, and to lever the head into the acetabulum at the same time.

I have since employed this method successfully in three other cases—one a child aged 9 years—and have found that the adductors stretch easily without any kneading or hacking with the hand. The amount of force applied is under the complete control of the surgeon, the action of the towel converting the pelvis into a very efficient fixed point.

The accompanying illustration should make my meaning quite clear.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### HEMIHYPERTROPHY.

THE case recorded below is, I think, of sufficient interest to warrant publication.

The patient, a boy, was 12 years of age when first seen. The left leg, it was said, was short, and the right sometimes "pained." The father, mother, and seven other children were healthy. There had been a suspicion of inequality at the age of three weeks, and shortening of the left leg was definitely noticed when he started school at the age of five years: it was corrected by a boot. For the past five years there had been intermittent attacks of intense oedema of the right leg extending to the top of the thigh, starting with pain in the groin and accompanied by pyrexia, anorexia, and signs indicating toxæmia, but no vomiting. During the attack pain in the whole leg was extreme: the urine was scanty and dark (probably febrile), the face swelled as with toothache, and the arm throbbled and swelled. These attacks occurred irregularly and subsided with rest, lasting about ten days to a fortnight.

The right side of the body, including face, arm, and hand, was bigger than the left, but the enlargement was most marked in the lower limbs. There was oedema of the soft tissues, which increased on standing or walking, but subsided after two or three days in bed. The right leg was 2 inches longer than the left, and resulting scoliosis and limp were present. The right calf was 2 inches greater in circumference than the left, and the right thigh  $1\frac{1}{2}$  inches. On x-ray examination the bones were found to be normal, but the right was larger than the left. The urine was normal, and the Wassermann reaction negative.

The interest of this case centres, I think, round the intermittent attacks. It has been suggested that the enlargement might be due to a pituitary, a sympathetic, or suprarenal anomaly. I think this would be hard to reconcile with the condition, and feel that it is in all probability a diffuse unilateral lymphatic or reticulo-

endothelial hypertrophy. The attacks would then correspond to the intermittent inflammation which occurs in other lymphatic overgrowths, such as cystic hygromata.

B. L. McFARLAND, M.D., M.Ch.(Orth.),  
Assistant Honorary Orthopaedic Surgeon, Royal Liverpool  
Children's Hospital.

### POLYMASTIA.

Accessory nipples are common enough; bilateral accessory mammae are comparatively rare, and still more so when normal lactation occurs in them.

The subject of the accompanying illustration, aged 25, has just given birth to her first-born female child. Below each mamma is an accessory organ, that on the left

being a complete breast, with prominence, nipple, and small areola; whilst on the right side is a full-sized nipple with practically no areola and no mammary prominence—quite distinct, however, from the main gland. The accessory mammae are not visible ordinarily, being hidden by the overhang of the main organs. All four are secreting milk abundantly, though the accessory ones are not being used.

Is the condition purely accidental—that is, a congenital abnormality? If so, they should occur anywhere on the body, whereas they always, in my experience, appear in the "mammary line"—that is, anterior border of axilla, just below the main breast, or over the rectus sheath, though some authorities state they have been found on the outer side of the thigh. Or has man evolved from an originally polymastic type? If so, why are there so few "throw-backs"? The child has not inherited the condition.

Penzance.

G. B. RICHARDSON, F.R.C.S.Eng.

### GALL-STONES WITH ACUTE PANCREATITIS AT THE AGE OF 16.

The association of gall-stones and cholecystitis with the great majority of cases of acute pancreatitis has been recognized for a good many years, although there is still some controversy as to the method by which these conditions may cause pancreatitis. The principal rivalry lies between two views—either that the pancreatitis is due to a spread of some infection from the gall-bladder through the lymphatics, or that infected bile regurgitates into the pancreatic ducts from the common bile duct, this process occasionally being due to the impaction of a gall-stone at their common opening at the ampulla of Vater. The following case appears to be a good example of the latter sequence of events, and, occurring at the remarkably early age of 16, is sufficiently unusual to be recorded.

A girl, aged 16, was admitted to the Wolverhampton and Staffordshire Hospital in October, 1926, with the history that thirty-six hours previously there had been a gradual onset of pain in the upper abdomen, with nausea, loss of appetite, and, later, vomiting. In the last twelve hours the pain had settled to the lower abdomen, and was then more marked on the right side. The bowels had not been open for three days, but she stated that this was not unusual. There was no history of any previous abdominal trouble.

She did not appear to be very ill; the temperature was 99°, and the pulse 116; there was no cyanosis. All over the abdomen rigidity and tenderness were present, though not very marked; the point of maximum tenderness lay over the upper part of the right lower quadrant, while the left lower quadrant was the part least affected. I made the not unusual diagnosis in such cases of "acute appendicitis," and operated for this condition.

#### Operation.

On opening the abdomen through a right pararectal incision I found the peritoneal cavity contained a large amount of straw-coloured slightly turbid watery fluid. The appendix was normal. Four or five small spots of fat necrosis were found on the mesentery and the omentum, whilst a mass could be felt in the upper part of the abdomen. A drainage tube was placed suprapubically by a stab wound, and the first wound was closed. A

right paramedian incision made above the umbilicus exposed a soft mass, about 4 by 2 inches in size, of a dark, almost black colour, lying between the stomach and the transverse colon, and arising from the head of the pancreas. This mass was incised freely, showing necrotic tissue. The gall-bladder was felt to be slightly distended and to contain a number of small gall-stones. Two tubes were left in to drain the necrotic area, and the wound was then partially closed. The gall-bladder was not drained as the condition of the patient was not good towards the end of the operation.

The patient survived for five days after the operation, her appearance during the last three days being that of a case of diffuse post-operative peritonitis. Glycosuria appeared for the first time twenty-four hours after the operation. There was no cyanosis, except in the last thirty-six hours, when the circulation was failing.

#### Post-mortem Examination.

The subcutaneous fat was soft and friable. There was peritonitis with free pus bathing the coils of small intestine in the lower abdomen. In the pancreas all normal tissue had disappeared from the head, which was replaced by a sloughing mass with extensive areas of fat necrosis around it; this was almost black in appearance, but had no haemorrhage of any size. The ducts in the pancreas could not be identified in the necrotic area. There was no sloughing in the body and tail of the pancreas, which were firm and contained occasional bright yellow spots of fat necrosis. Considerable fat necrosis was found around the tail of the pancreas and in the fat around the left kidney. The gall bladder contained a large number of small yellow faceted stones, but was of normal size, with only a slight degree of inflammation of the wall. The common bile duct was slightly dilated and contained about twelve small gall-stones, whilst one stone about  $\frac{1}{4}$  inch in diameter was found in the ampulla of Vater.

I am indebted to Mr. W. F. Cholmeley, under whose care the patient was admitted, for permission to publish these notes.

BASIL M. TRACEY, M.B., B.S., F.R.C.S.,  
Late Resident Surgical Officer, Wolverhampton  
and Staffordshire Hospital.

Norwich.

### FRACTURE OF THE NECK OF A RIB BY INDIRECT VIOLENCE.

We are unable to find any record of this accident in the literature, though, by the courtesy of the librarian of the Royal Society of Medicine, we append references to similar fractures of the bodies of ribs by muscular action.

A man, aged 60, but appearing ten years younger than his declared age, spare, wiry, and athletic, reported on September 2nd last that eight days earlier he had suddenly experienced severe left lumbar pain whilst driving at golf. This had almost disabled him at the time and had persisted. Examination disclosed a round, soft, tender swelling, about the size of a florin, in the left lumbar region, three inches from the middle line and two inches below the twelfth rib. It was unattached to the skin, which moved freely over it, and it became more pronounced and was more tender when the lumbar muscles were put into action. Support gave immediate partial relief. It was evidently due to muscular herniation through a tear in the fascia. There was then no indication of any other injury, though the patient, from a previous experience, several years earlier, of fractured ribs in another situation, expressed his belief that a rib had "gone." Repeated external investigations directed to this point failed to elicit any confirmation. In spite, however, of the relief given at first by strapping, and later by a broad Churton's bandage, the pain continued to cause much disability, and in course of time became more definitely centred round the area of distribution of the tenth left dorsal nerve rather than in the lumbar muscles. This localization being difficult to explain by the muscular injury three segments below, a radiograph was taken by Dr. Brailsford on September 17th. This disclosed "a fracture of the neck of the tenth left rib and osteo-arthritis of the lumbar spine." The fracture is transverse, midway between the tubercle and the head, with very slight disturbance of alignment.

The arthritic changes are probably due to a marked gouty diathesis.

The simultaneous production of two such lesions as the result of muscular action is remarkable. The special points of interest are two: (a) that the acme of the strain fell on two points some four inches apart; (b) that the strongly supported neck of the tenth rib (rather than the body) should have been fractured, presumably by torsion.

## British Medical Association.

## CLINICAL AND SCIENTIFIC PROCEEDINGS.

## LEEDS DIVISION.

*Difficulties in Cardiac Diagnosis.*

A MEETING of the Leeds Division, to which all members of the medical profession in Leeds and district were invited, was held in the board room of the General Infirmary at Leeds on February 17th. The chairman of the Division, Dr. A. HAWKARD, presided, and a British Medical Association Lecture was given by Dr. JOHN PARKINSON, physician in charge of the cardiological department at the London Hospital, on common difficulties in cardiac diagnosis.

Dr. Parkinson said that the time at his disposal would permit of a brief description of only a few of the numerous points in cardiac diagnosis. Palpitation was a clinical entity, common to many conditions, but most frequently met with apart from organic heart disease. Its basis had often to be looked for in hypersensibility of the nervous system, and in toxic and dyspeptic conditions. In simple tachycardia the heart rate was normal when the patient was undisturbed, but the response was excessive on exertion or emotional excitement. It was not a heart affection, but occurred under various conditions, such as pulmonary tuberculosis, exophthalmic goitre, and neurasthenia. The attacks began and stopped gradually. The trouble might be lifelong, and might not be due to any definite cause; it might interfere with the amount of exertion possible. In simple paroxysmal tachycardia the attack began and ended quite suddenly. Change of posture, exertion, and emotion did not alter the pulse rate. The condition was compatible with long life, and no definite cause might be obvious. In ventricular extra-systoles the pulse tracings showed intervals between two normal beats of exactly the length of two normal periods with the extra-systole intervening. The venous pulse showed a normal *a* wave and an abnormal *c* wave corresponding to the ventricular extra-systole. Extra-systoles might disappear; they might be a lifelong complaint, and might not always be traceable to any definite cause. The pulse tracings in auricular fibrillation never showed a regular pulse; the contractions were entirely irregular in time and force. This irregularity was the real difference between the pulse tracings of this and of other cardiac irregularities. In a tracing, for instance, showing extra-systoles there were portions of the tracing quite regular. The term "regular" as applied to pulse tracings did not convey definite knowledge.

The diagnosis of cardiac pain was of the utmost importance. Cardiac affections unattended with pain were the more numerous, diagnosis was admittedly difficult, and mistakes were common. As to the site of cardiac pain, the term "precordial" was vague and conveyed no definite meaning. The term "sternal" was more descriptive, and it might be any part of the sternum. Pain at the apex or below the left breast and down the left arm did not necessarily mean angina pectoris, but might be neuralgic in character. The pain in angina pectoris commonly ran across the chest above the breasts to the right shoulder or to the left shoulder, and down the inner side of the arms; the area of distribution of pain might include the neck and the lower jaw. If the right arm and the neck were affected the condition was very likely to be true angina pectoris. Recently a variety of angina pectoris had been separated off due to coronary thrombosis and cardiac infarction. In this condition there was, with the patient at rest and apart from any stress, a sudden onset of pain across the sternum extending to both arms, neck, throat, and back, in which the patient was collapsed, with vomiting and sweats, suggestive of acute abdomen, referable to the stomach or liver regions, with low temperature, low blood pressure, and lasting for hours or days. Such a seizure differed from angina pectoris, in which the onset was during exertion, the duration short, and the patient immobilized, but in which there was no vomiting or alteration of temperature and blood pressure.

The morbid condition in cardiac thrombosis was usually arterio-sclerosis; other morbid conditions, such as syphilis

and high blood pressure, caused a small proportion of the cases. In arterio-sclerosis there was a loud aortic second sound. Arterio-sclerosis might result in angina pectoris, or be a complication of it. In regard to enlargement of the heart, if the heart was really enlarged this meant a serious and dreaded condition, and great care should be taken to avoid the use of this expression unless the diagnosis was certain. For the determination of cardiac hypertrophy percussion was only roughly correct; an x-ray examination was necessary for definite diagnosis.

The lecturer showed a large number of lantern slides illustrative of his subject, and particularly laid stress on the presence, in arterio-sclerosis, of enlargement of the ascending aorta and a prominent knuckle in it on the left side near the clavicle.

In the discussion which followed Professor WARDROP GRIFFITH agreed about the doubtful value of percussion. He illustrated the point by the true story of two eminent professors who, when blindfolded and set to percuss a heart, failed ignominiously. He mentioned the value of palpation in estimating the size of the heart, and the necessity, in the case of a small thorax, of recollecting the relative size of the heart and the chest. Dr. BARNES inquired about the prognosis in reduplication of heart sounds, and Dr. PARKINSON replied that in many cases there was no prognostic significance, but that oedema indicated a grave prognosis.

The lecture was listened to with great interest and much appreciation, and a hearty vote of thanks was accorded to Dr. Parkinson on the motion of the CHAIRMAN, seconded by Professor GRIFFITH.

## Reports of Societies.

## THE SCOPE OF SURGERY IN CHRONIC ARTHRITIS.

A MEETING of the Medical Society of London, with the president, Mr. H. W. CARSON, in the chair, took place on February 27th. An interesting ceremony was the bestowal of the honorary fellowship of the society upon Sir Thomas Barlow.

Mr. MAX PAGE opened a discussion on the scope of surgery in the treatment of chronic rheumatoid and osteoarthritis. A full abstract of his paper is published at page 343.

Mr. HARRY PLATT (Manchester), continuing the discussion, said that the classification of the various types of chronic non-specific arthritis could not be better made than under the two headings rheumatoid arthritis and osteoarthritis. This classification offered a sound basis for a consideration of the role of surgery in such affections. In rheumatoid arthritis surgical measures, and more especially reconstructive operations, had a limited application. It was unnecessary to consider in detail the correction of deformities by such well-recognized methods as gradual stretching, cautious manipulation under anaesthesia, open division of contracted joint capsules, osteotomy, or arthrodesis. The speaker's experience of the operation of synovectomy, occasionally practised in the major joints, was disappointing. Pseudarthrosis operations were also unsuitable, except for bilateral ankylosis in important joints, such as hip or elbow. In osteoarthritis a more promising field was available. Osteoarthritis of the hip-joint—a definite clinical entity—presented most opportunities for surgical intervention. The patient sought relief, either because of intolerable pain or because of the disability of lameness due to increasing joint stiffness. Four methods were worthy of consideration, each having its definite indication. The first was forced movements under anaesthesia. This was often followed by temporary relief from pain and the restoration of a fair range of movement. The procedure could be recommended in younger patients where the joint change was in an early stage. The second method was excision of osteophytes, thickened capsule, and other formations. Such operations were based on the procedure known as cheilectomy; their scope was very limited. The third method was arthrodesis, which was the pivotal operation in osteoarthritis of the hip. This was eminently suitable in the younger and more

robust patients. Ankylosis was not easy to obtain owing to the extreme sclerosis of the joint surfaces. There were certain drawbacks to arthrodesis, one being the abnormal strain thrown on the lumbar spine, expressed in terms of backache, but that should not dissuade surgeons from regarding arthrodesis, with all its limitations, as the method of choice. The fourth method was reconstructive excision of the femoral head, an operation which gave good results in older patients. A comfortable joint with a limited range usually resulted. The operation competed to a certain extent with arthrodesis. It took a shorter time to carry out, at least in his own hands, and it gave the patient perhaps a movable or at least a comfortable hip. Finally, he mentioned that the combination of spondylitis deformans with bilateral ankylosis of the hip-joint (*spondylose rhizomélique*) was by no means rare. The condition took many years to develop, and before the stage of ankylosis was reached little could be done. After the hip-joint had fused it was urgently desirable to mobilize one side by carrying out a pseudarthrosis below the level of the joint.

Mr. HERBERT FRANKEL (Harrogate) said that the hip-joint cases which he had had to tackle had been practically all of them cases of the osteo-arthritic variety in elderly subjects. The three cardinal indications for operation were relief of pain, restoration of mobility, and correction of deformity, but it was the first of these almost always that brought the patient to the surgeon. Most patients were very clever with a hip which was merely stiff, but pain drove them to seek relief. The operation best suited for this condition was remodelling or reconstruction of the head of the femur. He had found in practically every case on which he had operated that the capsule, instead of being a thinish membrane allowing a certain amount of movement, was very much thickened, contracted, and actually adherent to the articular femoral head. As to the results of this operation, the pain had been removed and a few degrees of added mobility secured, but even a small amount of extra mobility to these people was well worth having. The alternative was arthrodesis, extremely difficult to do, requiring a good deal more prolonged after-fixation, and offering no advantage in respect to mobility. Certainly in the cases he had tackled—mainly those of older people—the operation of arthrodesis would not have been an improvement on the one described. With regard to the knee-joint, an arthroplasty had been in some cases sufficiently successful to please the patient, if not to satisfy the surgeon.

Mr. McCRAE AITKEN said that the cases in which he had seen successful results had been mainly those in which the patient's disability was due to adduction and external rotation. Of these two he would place more emphasis on the latter as a straining factor in walking and in maintaining pain in the affected joint, more particularly the low backache pain from which these patients suffered. It was when the external rotation got corrected by the freeing of adhesions that these patients were made comfortable for a considerable time. More attention should be paid, both in the early positional treatment and in the after-treatment, following any operation, whether extensive or limited, to the position in which the patient was going to balance and carry weight afterwards. Postural balance was a very important factor to the patient.

Dr. WARREN CROWE complained that although the announced subject was the scope of surgery in arthritis, no speaker had defined that scope. In fact, there was no scope for surgery (he was not speaking of advanced orthopaedics) in arthritis at all. The disease must be extinct before the surgeon came on the scene. The surgeon was dealing with end-results, and if he confined himself to end-results he would have a certain proportion of successes, but the more he meddled with the disease when it was active the less successful would his total results appear. The scope of surgery proper, therefore, was limited to deciding at what stage it was safe to operate. In the treatment of arthritis three people were involved—namely, the general practitioner, the physician, and the surgeon. The two latter seldom came into the picture at all; the general practitioner was the man who treated

arthritis, and what it was necessary to do if possible in all public discussions was to try to impress on general practitioners the early results of simple orthopaedic surgery so as to avoid the "wheeled chair" deformity which was so very difficult to deal with afterwards.

Mr. GORFNER HOLMES said that there were some surgeons who maintained that no self-respecting physician should ever handle a splint. If that was so the surgeon came early into demand in the case of arthritis. The point as to when surgical treatment should be started was very important. In the spa hospitals patients were seen in all stages of arthritis, but the more he saw those cases the more he sympathized with the difficulties the general practitioner had to contend with in the early stages. There was nothing more humbling to the man who had handled the late stages of arthritis with some freedom and success than to be called upon to handle the early and most difficult stage, and know when to splint and when to manipulate.

Dr. C. W. BUCKLEY (Buxton) quoted the case of a patient who had been suffering from arthritis for a period of fifteen years. Within the last two years one knee—the worse of the two—had been arthrodesed, and on operating the marrow of the bone was found to be soft and absolutely of the consistency of butter. The bone, however, was placed in position, and the patient kept in plaster-of-Paris for three months. Since the operation there had been no trace of pain, and the whole condition of the patient had improved to an extraordinary extent. That was an indication that it was sometimes desirable to operate for relief of pain even if the disease had not completely subsided. Many of the knee-joint cases which were beginning the chair-life were doing so through habit which had led to a spasm of the hamstrings and a contraction of the capsule of the joint. He was disappointed not to have heard more of the application of manipulative surgery to conditions of that kind.

Mr. MAX PAGE, replying to the discussion, said that the remarks of the various speakers had emphasized the fact that, at any rate, the surgeon could relieve the final stages of advanced joint change. With regard to the value of all these operations it must be a matter of several years before the merits of arthroplasty and arthrodesis on the major joints could be exactly assessed; the results were yet young. No mention had been made in the course of that discussion of the very useful part played by surgery in relieving arthritic conditions of the smaller joints—for example, of the fingers—but that was a field in which much good could be done.

### CHRONIC APPENDICITIS IN CHILDREN.

At a combined meeting of the Sections of the Study of Disease in Children and of Surgery of the Royal Society of Medicine on February 24th a discussion was held on chronic appendicitis in children. Mr. G. E. WAUGH, president of the first-named Section, was in the chair.

Dr. ROBERT HUTCHINSON, opening for the Children's Section, raised the question whether there was such a condition as chronic appendicitis in childhood. He did not agree with the statement that in childhood appendicitis was either acute or non-existent; it was, however, rare to meet with the chronic condition. He asked whether chronic appendicitis always arose out of an acute attack, or might it be chronic from the start. If an acute attack necessarily preceded the chronic disease, then the history should reveal some such event; it was not always discernible, though it might have been too mild to have received much attention. There seemed to be no reason why the disease should not be chronic throughout, as in the case of tonsillitis. He did not think "appendix dyspepsia" occurred in the child; it was rather an affection of the colon than of the stomach which was apt to be simulated. In the child recurring episodes of abdominal pain were more common, with or without vomiting and slight fever, lower abdominal pain being the most constant. If the patient was only seen between attacks there might be no physical signs. If there was no tenderness elsewhere, pain on pressing over McBurney's point was significant, especially if it was referred to the epigastrium. Pain confined to the

right iliac fossa was rarely due to chronic appendicitis, but if it came on after exertion rather than after meals it suggested that condition. Inflamed glands might give pain on palpation of the right iliac fossa. Radiography could not determine the diagnosis; indeed, it might only add another element of doubt. Many conditions might simulate chronic appendicitis in childhood; enlarged glands, kinking of the ileum or appendix, a mobile caecum, and an adherent Meckel's diverticulum could not be certainly distinguished from chronic appendicitis, nor from each other, except by exploration. Ureteral obstruction by stone should be distinguishable by x rays and by examination of the urine and urinary passages. Pelvic affections in girls could be detected by bimanual rectal examination, if necessary under an anaesthetic. Ovarian pain without a discoverable organic basis might occur in girls at about puberty, and ceased with the establishment of regular menstruation. It might be impossible to distinguish pain arising in the colon from the pain of appendicular origin; the former was very common in childhood, and was sometimes accompanied by vomiting. The more frequent the pain and the closer its relation to meals, however, the less likely was the condition to be chronic appendicitis; in intestinal colic a long retrocaecal and adherent appendix might be the cause. Slight attacks of appendicitis of acute form were often mistaken for bilious attacks. Some surgeons seemed to believe that appendicectomy could cure cyclical vomiting; his own view was that true acidosis attacks, with repeated vomiting and the presence of acetone bodies in the urine, were of hepatic origin, but the child with acidosis attacks was likely to have appendicitis. His own practice, when brought into contact with a child who had recurrent abdominal pain, with or without fever and vomiting, and in whom chronic appendicitis was likely to be the cause, was to advise exploration of the right iliac region—not appendicectomy; this advice was the more readily given if the child was going abroad to school, or if the parents were anxious about the possibility of appendicitis, or if there was a strong family history of the disease. He did not promise a cure of the symptoms; he stated merely that the fears of an attack of appendicitis might now be set at rest. In the majority of such cases within his experience the symptoms had not been caused by appendicitis, yet in only a few cases was the result of the exploration entirely negative. In some a kinked appendix was found, in some there were enlarged glands or a band of some kind; very generally there was some condition which justified the exploration.

Mr. A. J. WALTON, speaking from the surgical side, said that his view was that chronic appendicitis in the adult rarely occurred as a primary disease; it resulted usually from an acute attack. Most patients with so-called chronic appendicitis had atonic conditions of the caecum associated with vaginal ptosis. In the acute variety of appendicitis he included cases having gangrenous, perforated, and seriously inflamed conditions. In his category of chronic cases were those without active symptoms, even though the condition was a late sequel of an acute attack, and also those with distension, fibrosis, and stricture formation, or external dense adhesions. Perhaps the category might include cases in which the appendix was not diseased, but showed senile atrophy or was involved in a Jackson's membrane. In 906 cases of appendicitis uncomplicated with other lesions 601 were classified as acute, 305 as chronic; there was about an equal incidence in the sexes. Of the patients 186 were under 14 years of age, and so came into the present discussion, but only 33 of them were chronic. In 17 the chronic condition had followed acute attacks which had subsided after careful medical treatment. Acute appendicitis still showed an alarmingly high mortality in children, hence any short illness associated with severe pain and vomiting should be regarded with grave suspicion. In his series there were five cases with enlarged mesenteric glands, especially those at the ileo-caecic angle. In these five there were short "colicky" attacks, though sometimes there was also a dull aching pain. In five cases of viscerotaxis in girls aged 13 there had been frequent attacks of pain in the right iliac fossa and lower abdomen; the attacks had been of only a few days' duration, and a significant differentiating point was that there was no accompanying inflammatory mass. In four of his

cases there were threadworms; the mild attacks had suggested appendicitis, and at the operation the appendix seemed to be slightly inflamed. The threadworms were found in the lumen. About 33 per cent. of cases of appendicitis occurred in children under the age of 14, and in them it was a more serious condition than in adults, probably because children were less likely than adults to notice earlier symptoms. He did not find any cases in early life which had been chronic from the beginning.

Mr. HERBERT W. CARSON referred to a paper which appeared five years ago in a medical journal in the United States suggesting that chronic appendicitis was a myth. He did not doubt, from his experience, that chronic appendicitis in children did occur, but in certain respects it differed materially from the condition in adults. With Dr. Hutchison he agreed that "appendix dyspepsia" did not exist in children, neither did they have the symptoms of viscerotaxis, though occasionally they had a mobile caecum. In children it was common to find the appendix in the dangerous "five o'clock position"—that is, hanging over the pelvic brim. He agreed with Mr. Walton concerning the occurrence of threadworms in the appendix; he thought they caused chronic appendicitis rather than an acute perforative lesion. Enlarged glands in the ileocaecal mesentery he did not consider were tuberculous from the outset; rather they were chronically inflamed glands upon which tubercle bacilli were easily implanted subsequently owing to low resistance. In distinguishing these enlarged gland cases from appendicitis he relied more on the character of the attacks than on either temperature or tenderness. In the former condition there were many attacks, but pain was not continuous between them, as it was in appendicitis.

Dr. G. A. SUTHERLAND was still of the opinion that chronic appendicitis did not exist in children. He criticized one reason given by Dr. Hutchison for advising surgical exploration of the right iliac fossa—that, namely, of relieving the parents' fear lest the condition might be appendicitis; this he regarded as an instance of treating the parents instead of the child—a sort of conspiracy against the child's physical well-being. He would deal with such a child on much the same lines as a doubtful heart case—by letting it play about and carefully observing the result.

Mr. V. WARREN LOW deprecated the ideas expressed by Dr. Sutherland, and thought that to allow a child with such symptoms to run about would invite such a disaster as perforation.

Dr. A. P. CAWADIAS recommended that the terms "acute" and "chronic" in respect of appendicitis should be abolished; this would lead to a great clarity of conception, what was now spoken of as the acute disease being regarded as a paroxysm. Temporizations based upon the idea that a case might be only chronic had led to many disasters. It was better to risk an occasional operation for which there was proved to be small justification than to let a patient die, but the number of unnecessary explorations would be much reduced if a thorough examination were made, not only of the abdominal region, but also of the thoracic, and of the nervous system.

Mr. L. E. BARRINGTON-WARD did not think there was danger of any surgeon mistaking acidosis for appendicitis. Many cases showing symptoms such as had been described were due to alterations in the relation of the ileum to the caecum.

Mr. MAITLAND JONES admitted uncertainty as regards the diagnosis of chronic appendicitis in children, and desired more minute guidance as to symptoms. He agreed with Dr. Hutchison that in some cases it was quite good practice to "treat the parents."

The CHAIRMAN (Mr. Waugh) said that the pathologist could not give much practical help in this condition; it was necessary to weigh the probabilities in a symptom-complex which might be very varied. He drew particular attention to the primary tuberculous appendix, more common when the appendix was in a hernial sac than when in the abdomen, and also to the primary streptothrix appendix; he reviewed the subject in a general way from the surgical standpoint.

## RHEUMATIC INFECTION IN THE YOUNG.

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on February 24th, the president, Dr. S. MONCKTON COREMAN, in the chair, Dr. REGINALD MILLER read a paper on some public health aspects of juvenile rheumatism.

Dr. Miller dealt first with the prevalence of rheumatism in the young, and mentioned that in no country was rheumatic infection more common than in Great Britain, where it affected the elementary school children most seriously. Heart disease seemed to be more frequent among children leaving school than among new entries, and more common in urban than in rural schools. In secondary schools information about the prevalence of rheumatism was scanty, but the speaker quoted some figures supplied by Dr. Pearso Williams with regard to the Polytechnic Secondary School, which indicated that whereas the proportion of boys with rheumatic heart disease was 1.53 per cent. this was distributed unevenly, so that among scholarship boys from the elementary schools the incidence was 2.57 per cent., and among the fee-paying boys only 0.98 per cent.; this class incidence was an important point. Dealing next with mortality Dr. Miller mentioned some of the difficulties in estimating the death rate due to rheumatic infection, and after discussing various published figures concluded that the number of deaths due to rheumatic heart disease in this country was about 20,000 in each year. With regard to the invalidism caused by rheumatic infection in London it had been estimated that about one-quarter of the children absent from the elementary schools for long periods were those affected by rheumatic infection. Dr. Miller then dealt in some detail with the age and class incidence of the disease. Most of the first attacks occurred between the ages of 7 and 8, while at puberty the type of the disease changed to the adult variety. There appeared to be three reasons for the age incidence: chronic tonsillar infection, the beginning of school life, and the diminished resistance to infection shown during the years of childhood. Dr. Miller emphasized the point that rheumatism was a disease of the hospital class and was rare in private practice; but investigation of the lower limit of its incidence suggested that it was less common among the very poorest. He said that this view had been criticized, and he dealt with certain pieces of evidence, including some recently published work; a map of Birmingham with the incidence of rheumatism marked upon it did not resemble at all closely another map defining the areas of poverty. The deductions from this peculiar class incidence of the disease were that rheumatism was not altogether governed by poverty, nor did it spread by infection. Dr. Miller went on to affirm that juvenile rheumatism was essentially an environmental disease. He quoted the report of the Medical Research Council, which indicated that in Poor Law residential schools rheumatism was very rare, and yet these children came from homes where they would certainly have contracted rheumatism had they not been removed. The absence of overcrowding, the provision of good food, the short distance necessary to get to school, and the prevention of sitting in damp clothes were no doubt important, and there was evidence to show that the housing of children of this class was an important consideration. Dr. Miller mentioned the association between tonsillitis and juvenile rheumatism, adding that chronic tonsillar sepsis was present in about 85 to 90 per cent. of rheumatic cases. He emphasized the importance of damp dwellings in the production of rheumatism, and said that rheumatic infection attacked children through the tonsils; cold and damp dwellings predisposed children to recurrent attacks of catarrhal colds. The disease was commonest in cold, damp countries, and some unpublished work by Mrs. F. G. Shrubbsall showed that the sites of the homes of rheumatic children tended to be in low-lying areas and to follow the watercourses. Other evidence quoted included the report of the Committee on Rheumatic Heart Disease of the British Medical Association (SUPPLEMENT, July 3rd, 1926, p. 3), which showed that 62 per cent. of all rheumatic children investigated were found to be living in obviously damp homes; a recent series of cases in West London

investigated by the speaker gave much the same results. The reason why the very poorest families escaped rheumatism was that the overcrowding of many people into one room tended to keep it warm and dry. Dr. Miller then dealt with the organized effort against juvenile rheumatism, and said that the difficulty of obtaining the support of the public in the work of prevention and the task of providing dry and warm homes for the poor classes seemed very great. Notification had been tried in Paddington for some months, and despite the legal limitations of the type of case which could be notified the speaker thought this procedure was well worth while. The supervision of rheumatic children, especially by the children's hospitals throughout the country, was rapidly increasing and Dr. Miller mentioned the importance of calling such centres "rheumatic" rather than "cardiac" if they were to perform their true function of preventing heart disease. He referred also to the need for further accommodation for cardiac patients requiring prolonged rest in bed, and urged that such facilities should not be too far from the metropolitan hospitals. Dr. Miller dealt finally with the role of the school medical service, which, he urged, should secure the warming and drying of all children arriving damp at school; he also asked that certificate stating that a child should not attend on wet days or only for half-days should be allowed. Dr. Miller stated that in his opinion the ordinary routine of school medical inspections failed to discover the rheumatic child or the victim of heart disease in the great majority of cases. Treatment should be undertaken only by those who had the facilities for dealing with every possible rheumatic emergency; it should not be conducted at minor ailment centres.

Dr. J. TERTIUS CLARKE, in a paper on the pathogenesis of rheumatic fever in its climatological relationship to a possible insect carrier, said that during thirty years' service in the Malay Peninsula he had never seen a case of rheumatic fever, chorea, or subcutaneous nodes, and he had never found mitral stenosis at *post-mortem* examinations. Rheumatic diseases appeared to be very much less frequent in the tropics, and yet inflamed tonsils were as common in these parts as in England. He discussed the geographical distribution of rheumatic fever, mentioning first some of the difficulties in diagnosis. He quoted figures in support of his own observations that rheumatic fever did not occur in the tropics: Coming next to the question of the rat-flea *Ceratophyllus fasciatus*, the speaker showed that its distribution was in the temperate climes, corresponding closely with that of rheumatic fever. The flea required a high but not excessive degree of humidity for all its life phases, in its larval and most delicate state a wet skin killed it almost at once. Its host, the brown rat, lived in out-of-door burrows and under dwellings. The flea was essentially a town flea, and would only bite certain persons, which might perhaps explain the rheumatic diathesis. Dealing with environmental conditions, Dr. Clarke said that damp town houses were favourable to rats, and therefore encouraged rat-fleas. Since the flea had a very long life, sometimes more than 600 days, it might be the meteorological conditions of the earlier months of the year which produced the peak of rheumatic infection in the late autumn months. Dr. Clarke then discussed the similarity between the lesions of rheumatic fever and those produced by other protozoal infections, and summarized the evidence against the streptococcal origin of the disease. He believed that the disease was caused by a protozoon or spirochaete which was carried by the flea *Ceratophyllus fasciatus*.

The president, Dr. COREMAN, mentioned some of the difficulties of accepting Dr. Miller's deductions, remarking that in many rural districts the conditions with regard to damp were quite as bad as in the towns. Dr. J. A. GROVEN dealt with some of the evidence which Dr. Miller had brought forward. He thought that the class incidence which appeared in the figures quoted was due to the fact that most of the investigation on rheumatism had related to children coming from the better parts of the towns and not from the very poorest neighbourhoods. Close analysis of figures obtained at St. Thomas's Hospital did not support the hypothesis that the very poorest classes escaped; what evidence there was pointed the other way. Dr. F. G. SHRUBBSALL discussed the question of the sites of the houses

from which rheumatic cases came. It was a curious fact that aliens living under the same conditions appeared to escape the rheumatic infection which afflicted English children. He replied vigorously to Dr. Miller's criticisms of the school medical service. Dr. J. NANN DONNIE emphasized the very careful nature of the examinations made by the school medical service. He mentioned a special investigation he was making on 100 rheumatic children, and he described the type of pre-rheumatic child for which he was constantly looking among the entrant children.

### HYSTERECTOMY IN PUERPERAL SEPSIS.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on February 17th, the president, Mr. COMYNS BENKELEY, in the chair, Dr. BERNHARD SOLOMONS showed specimens of two uteri which had been removed for puerperal sepsis.

Dr. Solomon emphasized the difficulty of determining the optimum time at which a hysterectomy should be performed in cases of puerperal sepsis. He regarded a continued raised temperature and pulse rate in spite of treatment, an arrest of involution, the presence of irregularities on the surface of the uterus, and an offensive discharge as cardinal signs that this treatment might be adopted. The first patient had a prolonged illness, and it was not until the twenty-fifth day that it was decided to remove the uterus. At the operation this was found to be in great part necrotic, and Dr. Solomon showed a drawing of the uterine wall. The patient died soon after operation. In the second case, after a very difficult delivery owing to a complicated presentation, there was continuous pyrexia. A fortnight after the labour his manual examination suggested the formation of a uterine abscess, and a hysterectomy was performed. This patient made an almost uninterrupted recovery.

### Multiple Myomas in Young Patients.

Mr. J. ELLISON read a communication entitled "Two extreme cases of multiple myoma in sisters under 25 years old." The first patient was 24 years old, and was first seen when two months pregnant. She was complaining of severe pain, and the uterus was much larger and more irregular than the duration of pregnancy would suggest. Mr. Ellison opened the abdomen and found a very large number of fibroid growths scattered over the surface of the organ. A subtotal hysterectomy was performed and the patient made an uninterrupted recovery. Her sister was seen by Mr. Ellison soon after and was found to have an enlarged, retroverted uterus of irregular shape, suggesting the presence of multiple fibroid tumours. She had complained of abdominal pains for a considerable time, and curetting did not relieve them. Mr. Victor Bonney operated, as he was doubtful about the condition of the appendix. He removed ninety-five fibroids by multiple myomectomy, and the patient made a good recovery. When Mr. Ellison last saw her she was well and had no return of abdominal pain.

### Pregnancy and Epidemic Encephalitis.

Mr. FREDERICK ROQUES read a paper on pregnancy and epidemic encephalitis based upon twenty-one cases, of which he had full notes, and upon some 200 other cases collected from the literature. He considered the influence of pregnancy, labour, and the puerperium upon acute epidemic encephalitis. He believed that pregnancy exerted no untoward influence upon the disease. He also found that the process of delivery did not produce any marked improvement in patients suffering from encephalitis. With regard to the influence of the disease upon labour, there seemed to be no tendency to miscarriage or premature labour. The process of labour itself seemed to be exceptionally easy in cases complicated by acute epidemic encephalitis. It appeared that the senses of such patients were dulled, and their capacity for perceiving pain abolished or diminished. After labour retention of urine occasionally occurred, and might be due to central paralysis, resulting from the disease. Mr. Roques's study suggested that the encephalitis had little effect upon the child, though he thought that epidemic encephalitis neonatorum

was a rare but definite clinical entity. The author then considered the question of Parkinsonism and its relation to pregnancy. He discussed the diagnosis of encephalitis as a complication of pregnancy, and in conclusion drew attention to various points in the treatment.

### HISTOLOGY OF THE GLOBUS PALLIDUS.

The usual quarterly meeting of the Royal Medico-Psychological Association was held on February 16th at the City Mental Hospital, Fishponds, Bristol, the chair being occupied by the president, Dr. HAMILTON MARR. A resolution of appreciation of the good work done for many years by Sir Frederick Willis as chairman of the Board of Control was carried with acclamation.

Dr. E. BARTON WHITE read a paper entitled "Some points in the histology of the globus pallidus." He said that among the changes in this body in different diseases various authors had referred to striking changes in the walls of the blood vessels, manifested as a deposit of an amorphous material in their outer walls which was often sufficient to obliterate their muscular and elastic fibres. The process simulated calcification. One-half of the hundred cases examined by Dr. Weston Hurst at Queen Square Hospital showed this change in the vessels, sharply limited to the anterior half of the globus pallidus; the ages of those patients ranged from 20 to 81. Hurst had shown that the material was not calcium, but a large portion of it was easily stainable iron; the material was also detected lying free in the corpus striatum. Hurst found that the deposit did not represent a senile change, that it was not related to arterio-sclerosis, and that in some of the cases no pathological change could be seen in the nerve cells of that nucleus. These deposits seemed to indicate, in that worker's view, a proclivity for the globus pallidus to degenerate in the second half of life. Dr. G. Hadfield had shown that acute bilateral necrosis might affect the part of the globus pallidus in which the vessel change was found, and that a rich deposit of iron salts was present in the walls of the vessels of the pallidus in half the persons examined who had no chronic nervous disease, their ages being over 50. Dr. Barton White's figures corresponded with these. The paper was supported by the exhibition of a series of very convincing slides, and the speaker submitted, as his conclusion, that the deposition demonstrated was as frequent in all forms of mental disorder as in chronic neurological cases and as in normal brains, and that therefore it could not be regarded as pathognomonic of any particular nervous disease, as some had previously contended.

Dr. GEOFFREY HADFIELD said the deposit was not a minute microscopical quantity, but that it could be easily detected with the aid of a hand lens. Many had concluded that the change in the vessels was pathological and that it caused, or largely contributed to, neurological signs and symptoms; it had, for instance, been suggested as a cause of post-encephalitic Parkinsonism, also as playing a large part in the causation of paralysis agitans. The change must be related to the fact that the globus pallidus was very rich in iron salts, as could be readily seen by putting a slice of brain into potassium ferrocyanide and hydrochloric acid, when it rapidly became a deep blue. An investigation led him to the conclusion that the iron which appeared in the vessel wall came from the nucleus itself, and was therefore intrinsic iron; he also considered that it was derived from a precursor in the nucleus which did not stain. The site of the deposit in the nucleus strongly suggested that the process was actually a degenerative one. It was, he said, tempting to think that perhaps the globus pallidus was a vestigial structure which was undergoing evolutionary atrophy. There seemed to be no specific association with diseases. It was a possibility that this deposition of iron might predispose to disease; it certainly would alter the permeability of the vessels. The condition always seemed to be absent in children, but in old people it was frequently found.

Professor E. FAWCETT agreed that the globus pallidus was one of the oldest parts of the encephalon, and thought that Dr. Hadfield's suggestion that a degenerative process

resulted in these depositions seemed fairly sound. Dr. J. R. LORN mentioned the importance to psychiatrists of the basal ganglion as being probably the seat of the central mechanism of the emotions. Dr. Brander at Bexley had investigated the presence of iron in cases of general paralysis, and had discovered it in large quantities. Dr. Barton White, however, did not appear to have arrived at the same conclusion. The presence of the iron in the globus pallidus might indicate a regression of function, and indeed that the structure was a dying one. The extent of regression would vary in individuals. Dr. G. E. PRACUMEL asked whether the author had investigated the brain of a patient who died of pernicious anaemia, and, if so, whether iron was found in that case. He inquired also whether there was any analogy between the reaction found in the globus and the staining and pigmentation discovered in the brain after haemorrhage.

Dr. BARTON WHITE, replying, said that in one case of four persons dying of general paralysis there was certainly no iron deposited.

Dr. HADFIELD, replying, stated that he had not examined any cases of pernicious anaemia, but that in that disease the pigment was taken out of the blood by a phagocyte. In the cases which had been examined there was no reason to suppose that there was any excess of iron in the circulating blood, nor in the pathological series as contrasted with the normal. He believed that the deposit occurred apart from any phagocytic cell action. He thought haemorrhage could be eliminated as a cause of the pigmentation or the change in the globus pallidus, since in the majority of these cases there was no sign of a pathological lesion.

#### *The Mental State in Cardiac Disease.*

Dr. CAREY COOMBS read some notes on the mental state in cardiac disease. He said he had reviewed about 2,000 cases of cardiac disease, and from them he had drawn certain inferences as to the connexion between such disease and mental disorder. He suggested answers to the following questions: (1) Was there evidence that mental disorder caused cardiac disease? (2) Did the circulatory disturbances arising from cardiac disease often upset the mental functions? (3) How far were both cardiac disease and mental disorder, when they occurred together, due to a common cause? In the war mental disturbance was often the chief factor in causing functional tachycardia, and mental stress and worry were appreciable factors in producing high arterial tension. He did not believe there was any form of heart disease which arose out of mental disorder. As to whether cardiac disease could be directly responsible for mental disorder, he had been impressed by the absence of unimpeachable evidence in support of such a view; still, severe cardiac disease was so terrible to contemplate that it might well upset the mental equilibrium of the person concerned, and also the deficiency in the cerebral circulation might result in mental trouble. It was rare to find insanity as a sequel of rheumatic heart disease. The incidence of insanity in uncomplicated heart disease was not higher than that of insanity in the general population. There were some conditions in which mental and cardiac symptoms appeared together and might be ascribed to a common cause. In persons with senile heart disease, for example, the failure of the heart to supply blood adequately to the periphery was only one of many factors concerned.

The PRESIDENT (Dr. Marr) thought there would be general agreement that heart disease *per se* seldom caused mental disorder; when mental disorder followed heart disease it could usually be ascribed not to cardiac conditions, but to the circumstances which brought about the diseased state—namely, the autotoxin or microbic effect on the blood. With regard to heart conditions affecting the mind, it was usually the mental condition which caused the functional aberration. This was certainly so in very many of the cases of shell-shock during the war; the heart condition usually came on after mental exhaustion.

Dr. LORN agreed with the president; the action of the heart was very much involved in the psychoneuroses and the neuroses. Insanity was so closely associated with the toxæmias that it was difficult in a given case of acute

insanity to decide whether the heart condition was due to the mental state or to the accompanying toxæmia.

The readers of both the papers were cordially thanked and, at the invitation of the hospital visiting committee, members and visitors lunched together, Mr. JOHN CURLE, J.P., mayor of Bristol, presiding.

#### HIGH BLOOD PRESSURE.

At a meeting of the Manchester Pathological Society held on February 8th, the president, Mr. F. H. WYRMACOTT, in the chair, communications on the subject of high blood pressure were made.

Dr. J. CRIGTON BRAMWELL and Dr. R. ELLIS in a joint paper referred to the difficulty in defining the upper normal limit of blood pressure. In common with many other physical attributes the range of variation followed the ordinary type of normal frequency curve. A systolic reading of 150 mm. Hg should not be regarded as necessarily pathological even in young people. There was little tendency for the systolic pressure to rise between the ages of 20 and 40, and even in healthy old people a systolic reading of under 150 was common. The high pulse pressure in old age was a compensatory mechanism to overcome the loss of elasticity in the arteries. Even apart from any structural change the elasticity of the arterial walls might be greatly impaired by a high diastolic pressure. Hence a relatively small rise in diastolic pressure would entail a much greater rise in pulse pressure if the heart was to maintain its output. In this respect a high diastolic pressure was just as important as a stiffened arterial wall in determining the limitation of exercise tolerance. The sphygmogram in cases of hyperpiesis resembled that of aortic stenosis, the maximal pressure in the aorta being attained relatively late in systole. With regard to prognosis in these cases, the condition of the kidneys was of the first importance. In primary hyperpiesia, though the pressure might be higher, the outlook was not quite so grave as in the renal cases; in these the age incidence was lower, and they generally ended in uræmia. The diastolic pressure was of special significance in relation to the ultimate prognosis, because it represented the liability which the heart was called upon to undertake. The systolic pressure, on the other hand, was more closely related to the immediate issue, since it indicated the capacity of the heart to meet its liabilities. A falling systolic associated with a rising diastolic pressure was always a very bad omen, in that it signified heart failure.

Professor J. SHAW DUNN said that an account of the morbid anatomy of persistent hypertonus might still very well start with a reference to the long-established fact that chronic nephritis, primarily a disease of the kidneys, commonly produced a high blood pressure. The available evidence, including the temporary rise of pressure in acute nephritis, pointed to the circulatory change being a reaction to impairment of excretory function. It might be that some potent but hitherto unrecognized pressor substance was retained in the body owing to impaired excretion, and so acted in excess on the vessels. Another explanation, no less likely, was that in accordance with Cushing's view all excretory substances were eliminated from the blood stream by filtration under pressure of the blood, and that where the field of filtration was limited a greater pressure was required to secure adequate elimination. In the more mysterious group of non-renal cases, or essential hypertonus, many of the morbid changes in the organs were of secondary character and of late development. These were degenerative phenomena such as cerebral haemorrhage and cerebral softenings, atheroma in arteries, and shrinkage of the kidneys. Local softening and patches of tissue atrophy seemed to depend at times on the blood pressure, though high, being inadequate to perfuse some of the vessels, the contraction of which helped to raise it. These degenerative changes varied markedly in degree in different instances; they appeared to be most marked in cases where death occurred from cerebral haemorrhage. In other instances, a smaller group where death was due to failure of cardiac compensation the arterial intima was frequently healthy and the kidney were smooth and of normal size or even larger. The

structural changes which might be said to occur in all cases of essential hypertension, or at any rate which were found even in the earliest cases at the *post-mortem* examination, were (1) hypertrophy of the left ventricle of the heart; (2) hypertrophy of the middle coats of the arteries generally, in Professor Dunn's experience invariably accompanied by some fibrosis of the media, a degenerative feature, but an earlier stage of pure hypertrophy might be presumed; and (3) changes in minute arterioles of the size of the afferents to renal glomeruli. An affected vessel showed thickening with fatty degeneration of its intimal coat, starting exactly at its origin from the parent trunk and extending throughout its length. From its distribution and character this lesion hardly suggested the action of a toxin in the ordinary sense; if such was concerned it was difficult to see why the parent vessel should escape damage so completely as it often did. The morbid condition seemed on the whole more likely to be due to a poor blood supply in the smaller vessel, resulting from contraction of the larger one. If this explanation of the change could be supposed to hold good then all the earliest structural changes in hypertension were mostly evidence of the mechanism for maintaining it, or of defects arising from the operation of that mechanism; the ultimate causal agency remained quite obscure. If this agency was an abnormal pressor substance it had still to be demonstrated. Other possibilities might be imagined on lines of analogy with chronic nephritis—such, for example, as the presence in the blood of a substance of low solubility which demanded excessive filtration for its elimination even by normal kidneys; lead and perhaps uric acid might suggest this type of action. Increased osmotic pressure of the blood colloids would also require a greater filtration pressure.

Mr. GEOFFREY JEFFERSON dealt with blood pressure readings in the course of operations, especially on the central nervous system. The systolic blood pressure and the pulse rate were recorded every five, or in some cases ten, minutes regularly, and the curves so obtained gave valuable information as to the condition of the patient, and some indication, at any stage, of his ability to undergo prolongation of the operation. In more than one instance patients whose systolic pressure had fallen as low as 45 or 50 mm. of mercury had made uneventful recoveries.

### FORCEPS DELIVERY AND PROPHYLACTIC GYNAECOLOGY.

A MEETING of the Edinburgh Obstetrical Society was held on February 8th, with Dr. HARC FLETCHER, the president, in the chair. Dr. LINDSAY (Glasgow) read a paper on the reduction of forceps delivery as a basis for prophylactic gynaecology.

Dr. Lindsay first described the various causes of intra-natal trauma affecting the birth canal, and suggested that this was often due to the application of forceps. The trauma might be visible to the naked eye, or might be almost microscopical, and in many cases was due to the over-stretching of the para-cervical tissue or pubo-cervical fascia. Ante-natal supervision should make it possible to minimize materially the number of forceps cases, and in Dr. Lindsay's opinion the only case which would require forceps delivery was the one where there was a moderate amount of overlapping of the foetal head at the beginning of labour. Forceps delivery would also be advisable in cases of occipito-posterior presentations which could not be rotated by hand, and in those difficult instances where there was resistance of the pelvic floor, and narrowness or tenseness of the introitus of the vagina was marked. He therefore emphasized the necessity for the careful teaching of ante-natal supervision to students. With regard to the standard indications for forceps delivery he thought that they could be very much reduced, since he did not believe, for example, that forceps were warranted in cardiac cases, Caesarean section being much more satisfactory. Foetal signs of distress were certainly definite indications for intervention, but such was only permissible when the labour had progressed sufficiently to make delivery a matter of safety for the mother; he saw no benefit in delivering a debilitated child quickly when such a rapid delivery would

entail a degree of maternal injury. In his opinion the mother should be the first consideration. In primary uterine inertia he was opposed to the use of forceps, since delivery could often be effected by emptying the bowel and the bladder, and by giving a hot vaginal douche. In secondary uterine inertia the uterus required a rest; morphine was indicated in such cases, and not forceps. Perineal rigidity should be treated by the administration of light anaesthesia, when relaxation usually occurred. If rigidity persisted anaesthesia, and such expedients as fundal pressure or administration of pituitary extract, would often evoke the necessary power. Until these simple methods had been tried forceps should not be employed for this minor indication. If forceps were necessary they should be employed in such a way as to prevent serious birth injuries; it had been proved that they were safe only when applied in the biparietal diameters. Dr. Lindsay considered the axis-traction forceps a dangerous instrument, for, when applied with the head in the oblique diameter of the pelvis, the vagina was pulled taut and forcibly twisted as rotation of the head progressed. This often caused extensive vaginal lacerations. In Dr. Lindsay's opinion the best instrument to-day was the Kielland modification, which was a long forceps and practically straight, the pelvic curve being almost negligible. This instrument was always applied to the biparietal cephalic diameter, no matter what the position of the head; it was smaller than the Milne-Murray forceps, and had no fixation screw or axis-traction apparatus. It remained under the control of the operator, who knew the amount of force he was expending. There was much less compression of the child's head, and, what was more, the compression was always maintained in the safest cephalic diameters. If the high forceps operation was to remain at all in obstetric practice then the Kielland forceps was the ideal instrument. Dr. Lindsay condemned the use of forceps as a lever and as a rotator, and concluded that it should be employed as a tractor and considered as a compressor, the latter action being only utilized in the planes where it would be most efficient and where the compression would least damage the child. He added that if this line of practice were followed it would be realized that the only safe forceps delivery which one could complete in those unfavourable surgical circumstances usually found in working-class areas was the low forceps operation.

### THYROIDECTOMY IN TOXIC GOITRE.

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on February 10th, the president, Professor A. FULLERTON, in the chair, Mr. D. KENNEDY read a paper on the operation of thyroidectomy for toxic goitre.

Mr. Kennedy advocated the standardization of the operation so as to lessen its dangers, shorten the convalescence of the patient, and improve the results. He recommended ligation of the vessels before they entered the gland tissue, whether the whole or part of a lobe was to be removed; in this way there would be no haemorrhage, the danger of shock was greatly lessened, and the post-operative condition of acute thyroid poisoning would not occur, at all events in a degree to endanger the patient's life. The steps of the operation should be thought out beforehand and performed with deliberation. Open ether well diluted with air was the most satisfactory anaesthetic, and 1/4 grain of morphine and 1/100 grain of atropine were administered about thirty minutes before the operation, the patient being always carried to the operating table. Local anaesthesia was not satisfactory, and combined local and general anaesthesia was useless and a waste of time. To expose the thyroid vessels fully, and to free the recurrent laryngeal nerve and the parathyroid glands from any danger of injury, the gland should be dealt with inside the capsule. The cut muscles should be accurately sutured to prevent scarring. Lugol administered in preparing the patient for operation helped to lessen the severity of the symptoms and to improve the condition of the patient, but its utility ceased after administration for a few weeks. Mr. Kennedy said that the results of operation had been gratifying; in suitable cases the mortality was nil, and complete

recovery was assured. No operation was advisable if the heart muscle was degenerated or where a pathological condition such as kidney disease had developed.

The PRESIDENT referred to the difficulties met with in operations for toxic goitre in connexion with the recurrent laryngeal nerve, which was often surrounded by the branches of the inferior thyroid artery, and thought that the question of shock following this operation was not so simple as Mr. Kennedy had made out.

Mr. S. T. LWIN suggested that Mr. Kennedy had failed to distinguish between exophthalmic goitre and toxic goitre; he believed that any surgeon who operated indiscriminately on cases of exophthalmic goitre would encounter fatalities. Every case of exophthalmic goitre should be admitted first into medical wards, and an operation should not be undertaken until a physician had recommended both the time when it should be performed and its extent.

Mr. R. A. STONEY agreed that ligation of the vessels was an essential preliminary to thyroidectomy, but if the thyroid was much enlarged the isolation and identification of the vessels were by no means simple. It was sometimes very difficult to reach the inferior thyroid vessels, and when there had been prolonged medical treatment, and especially x-ray therapy, so many adhesions were formed that it was almost impossible to free the gland. It might be hard to invert the lower pole of the gland and expose the inferior thyroid artery; in these cases he approached the inferior thyroid vessels from the inside, and it was thus possible to avoid the trachea, which often caused difficulty in respiration. He had tried local anaesthesia, but had not found it satisfactory. He always used rectal ether supplemented by a certain amount of open ether on the mask, which gave rise to no difficulty.

Mr. KENNEDY, replying, said that he would never hesitate to operate on any case of exophthalmic goitre, provided that the cardiac muscle was not affected. He looked upon the difference between exophthalmic goitre and toxic goitre as being one of degree. In operating on these patients difficulties were encountered with adhesions, but these had to be dealt with as in other operations. He did not ligature the pole, but tied the vessels directly; after ligation he divided freely and opened the lower pole.

#### *Obstetrical Fractures of the Femur.*

Mr. R. A. STONEY read a paper on two cases of obstetrical fractures of the femur.

An infant, 2 days old, was admitted to hospital with a fracture of the right femur at the junction of the middle and upper thirds, which had been produced in attempting to bring down one leg in a breech presentation. The child was treated by extension of the thigh in the vertical position. One month later the extension was taken down and the leg was x-rayed; the photograph showed malunion with considerable overlapping and backward displacement of the lower fragments, both fragments being surrounded by a large mass of callus. Two years later the child was again seen; she was able to walk and run perfectly, and the x-ray showed a femur which appeared perfectly normal except for a slight thickening of the compact tissue over the outer side of the bones in the region of the fractures. The medullary canal had been perfectly reproduced.

The second case was that of an infant, 8 days old, admitted with a fracture of the left femur at the same level, produced in the same way as in the former case. Though the limb was in a Thomas splint, the x-ray examination showed marked displacement. The case was treated with extension in the vertical position, and an x-ray photograph taken a month later showed union with abundant callus in excellent position.

Mr. Stoney said that according to some authorities the treatment of these cases was simple, merely folding the thigh on the abdomen and holding it there by a broad swathe. Plaster-of-Paris from the thigh to the ankle, with the thigh at right angles to the abdomen, was also said to give good results. One writer on surgical diseases of children had suggested that good results were obtainable in all cases by almost any treatment. From the experience of his two cases it would seem that extension in the vertical position was in every way satisfactory; the results were good, it was easy to nurse the patient, and the infant did not object to the position. Care should be taken to apply the extension plaster to the thigh as well as to the leg, and to see that the weight was sufficient to keep the buttock off the bed. It was advisable in these small infants to sling both legs, since if only the broken one was slung and the other was left on the bed, it was impossible to control the movements. The probable cause of the bad

result in the early stage in the first case was the fact that the sound leg was merely tied to the crossbar and was not counterpoised with a weight and pulley. It would appear, however, that at this early age a good first result might be confidently expected, even if the x-ray showed that the union was not automatically perfect.

#### VITAL STATISTICS OF WEALTH AND POVERTY.

At the meeting of the Royal Statistical Society on February 21st Dr. T. H. C. STEVENSON of the General Register Office read a paper on vital statistics of wealth and poverty.

Many attempts, he said, had been made to estimate the influence upon health of prosperity and the lack of it, but the extent of our ignorance of the subject attested the difficulties of its investigation. His paper described a method of dealing with it employed in the recently published report of the Registrar-General on occupational mortality during 1921-23, and discussed the degree of success attained in the light of the results arrived at. The method most commonly employed had been the comparison of returns for complete populations selected as representing wealth and poverty; but the samples so secured were far from pure or free from influence by other factors. If the contrasts in wealth and—what was probably quite as important in its influence on health—culture were to be obvious the numbers available for examination would be limited; and, on the other hand, if the field of investigation were extended the difficulty of assessing degree of local wealth and culture became formidable. Classification of individuals by income was not possible under present conditions in this country, though it had been employed on a very limited scale in America. Estimation of poverty by housing conditions was very unsatisfactory, as bad housing was only one of the handicaps of poverty, so that it was impossible to determine how far the excess of mortality associated with bad housing was due to poverty and how far to the direct effects of overcrowding, etc. Even if full details of income were available, these in themselves would not provide an ideal basis of classification, as it was probably the cultural associations of wealth which promoted longevity rather than wealth itself. The clergy, for the most part poorly paid, were singularly healthy. The method advocated for meeting the conditions to be considered was that of inferring social position from occupation. By this means regard could be paid to (average) culture as well as income, and the total occupied population could be included in the inquiry. The results attained by a scheme based on these lines had been described in the report referred to, and the regularity and consistency of the graduation so obtained of mortality from various causes appeared to be in itself evidence of the success of the social classification so arrived at. Instances of such regularity were quoted by Dr. Stevenson, mortality from many forms of disease increasing without interruption from a minimum in the highest to a maximum in the lowest social class. Respiratory diseases, including phthisis, furnished the most pronounced examples of this type of distribution, which tended to be reversed for diseases of the digestive system, and for diabetes in later life, mortality from appendicitis increasing without interruption from a minimum for the lowest to a maximum for the highest of the five social classes distinguished. The case of cancer was especially interesting. Mortality from this cause followed the usual type of social distribution, being lowest in the highest and highest in the lowest section of society. But this graduation was found to apply to cancer of certain sites only, mortality from the remainder being much the same for all classes. The graded sites, which were responsible for about half the total deaths (in males, for whom alone the requisite occupational information was available), alone the requisite occupational information was available, included the upper alimentary canal from mouth to stomach, inclusive, the skin, and the larynx. It appeared, therefore, that cancer of these sites was largely preventable, though the factors determining its differential incidence would first have to be recognized.

## Reviews.

### GAS POISONING.

THE publication in the Monograph Series of the American Chemical Society of a treatise on a problem in industrial hygiene by two well-known physiologists seems to us to be an event of real significance. It is a practical expression of that liaison between the laboratory and our social organization which many advocate in theory, but too seldom are at any great pains to realize in practice. The book which occasions this comment is by Professor YANDELL HENDERSON and Dr. H. W. HAGGARD, and is entitled *Noxious Gases and the Principles of Respiration Influencing their Action*. It will be agreed at once that the authors are well qualified to instruct us in the principles of respiration, and, further, that the sympathy towards questions of applied physiology which is betrayed in much of their work will incline us to listen to what they have to say on this grave problem of industrial gas hazards.

Readers of the *BRITISH MEDICAL JOURNAL* may recall two lectures by Professor Henderson which we had the privilege of publishing during his recent visit to this country. The substance of those lectures is the foundation of this book, and the same lucid argument and forcible persuasion will be encountered again. It is surprising that in the enormous library of toxicology there does not appear to have been any earlier book dealing specifically with the problem of the special nature of poisons which find entrance to the body through the lungs. It is well that the omission is now repaired, for, if we accept the statement of the authors, it is "almost the only field in the whole range of modern sanitation in which fatalities throughout the civilized world are increasing from year to year."

Four introductory chapters summarize those principles of respiration and of the behaviour of gases and vapours which are fundamental to the consideration of the absorption and elimination of volatile substances. As the authors acknowledge, the discussion goes much further than that in any current textbook in representing a vital function as a mechanism. For the practical problem in hand physiologists will not be inclined to quarrel with this adventure. The succeeding chapters are devoted to the classification of the chief groups of gases of social importance upon the basis of their physiological action. This leads to the separate consideration of asphyxiants, irritants, anaesthetics, and inorganic and organo-metallic gases. The general action, symptoms, and sequelae of each group are discussed, and a description follows of the special characteristics of individual members. The chemical field covered is comprehensive. A final chapter discusses the prevention and treatment of poisoning by noxious gases. A selective but adequate bibliography accompanies the text.

The authors write for chemists and engineers rather more than for medical men, because "in general chemists are in immediate contact and control, and are increasingly responsible for the human portion of the machinery of production, and for the determination and prevention of the poisonous aspects of the products which they manufacture." They believe that in this subject popular education has so far outstripped medical instruction that "police-men, electric linemen, and boy scouts frequently save lives that a physician cannot." Unless members of the medical profession are familiar with the matter of the book under review it will be difficult for them to challenge this statement.

### DISEASES OF NOSE, THROAT, AND EAR.

THE well-known work on *Diseases of the Nose, Throat, and Ear*<sup>2</sup> which, under the editorship of Dr. LOGAN TURNER, may be taken to represent the work and teaching of the Edinburgh School of Medicine has now achieved the well-

<sup>1</sup> *Noxious Gases and the Principles of Respiration Influencing their Action*. By Yandell Henderson and Howard W. Haggard. American Chemical Monograph Society Series. New York: Chemical Catalog Co., Inc. 1927. (Med. 8vo, pp. 220; 12 figures. 4.50 dollars.)

<sup>2</sup> *Diseases of the Nose, Throat, and Ear for Practitioners and Students*. Edited by A. Logan Turner, M.D., LL.D., F.R.C.S. Ed. Second edition, revised and enlarged. Bristol: John Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. 1927. (5½ x 9, pp. xxiv + 410; 234 figures, 11 plates. 20s. net.)

merited success of a new edition. From a modest origin it has developed into a comprehensive textbook, although it retains its previous character. Each section has been expanded where necessary, so that it is not merely brought up to date, but it is scarcely possible to discover any point about which useful information is lacking. The editor has evidently been a wise guide to his associates, and has so arranged the sections that the whole is well balanced, while there is a sober restraint and an absence of fads and fanciful ideas. This plain statement of the case, however, in some places is associated with a style so crude that improvement is really needed, and frequently some literary polish would be welcome, though this does not apply to all the sections. Opportunity has been taken to remedy some minor defects, and the illustrations have been improved, but it is sad that such an important group, as those depicting the stages of the mastoid operations are not more realistic, for as they are they would give but little help to an inexperienced operator. There is, however, no other book which includes laryngology and otology with such success, for there is no undue stress laid upon any particular section, which is the common failing of such books. Although it has reached its present size it is not unwieldy; but is packed with information, and has attained the right proportion between an elementary textbook and a work of reference. The present edition should surpass the previous issues in popularity.

Progress during the seven years which have elapsed since Dr. DAN MCKENZIE produced his *Diseases of the Throat, Nose, and Ear*<sup>3</sup> has induced him to enlarge the second edition, which is now issued, though time does not appear to have modified his views in any important details. The size to which this new volume has been expanded must give serious concern to the reader, although Dr. McKenzie has eluded the vigilance of his publisher; this great increase might have been avoided by a judicious selection of material and condensation of language, without omitting anything the least important. The author, as before, freely acknowledges the work of his colleagues and many others, although he gives comparatively few references, and these in no systematic fashion; throughout he makes it clear that the book is based on his own personal experience and opinions. The expansion is due, however, chiefly to the desire of the author to give acknowledgement to the observation of others—in such matters, for example, as tuberculosis of the larynx and meningitis. Valuable as the book is as the expression, not only of his own matured judgement, but that of the teaching school he represents, yet it does not attempt to be the book of reference and authority which a volume of this size might well have claimed to be. It must, however, be judged by the standard of the first edition, and the reader will certainly find here full information and advice on every point which can possibly be held to come within the provinces of otology and laryngology. There are various debatable topics upon which it would be easy to challenge the views of the author, and herein there is but little change from the first edition; but he has the courage of his opinions, and supports them with sound logic and argument. This edition, therefore, more than deserves to repeat the success of the previous one—to which it is certainly superior in its breadth of view—as a comprehensive work on the subject. It should be added that the book is published in a generous style and is magnificently illustrated.

Dr. SYME has enlarged the second edition of his *Handbook of Diseases of the Nose, Throat, and Ear*<sup>4</sup> to something like double the size of the first, and he has been wise to follow this policy of decompression, for the contents were so tightly packed that their utility was impaired. Even now the author attempts to cover a wide field in such a way that he is compelled to touch very

<sup>3</sup> *Diseases of the Throat, Nose, and Ear*. By Dan McKenzie, M.D., F.R.C.S. Ed. Second edition. London: William Heinemann. 1927. (Sup. roy. 8vo, pp. vi + 677; 254 figures, 3 plates. 45s. net.)

<sup>4</sup> *Handbook of Diseases of the Nose, Throat, and Ear*. By W. S. Syme, M.D., F.R.C.P. and S. Glas, F.R.S. Ed. Second edition. Edinburgh: L. and S. Livingstone. 1927. (Cr. 8vo, pp. xv + 400; 26 figures, 21 plates. 12s. 6d. net.)

briefly on many points. The book, however, gives a general representation of his own practice, without attempting to follow any orthodox lines. It is presumably addressed primarily to the students and post-graduates of his own teaching school, but it will be found a useful guide to any house-surgeon or during a short course of post-graduate instruction. If Dr. Syne has not put forward the full capacity of otology and laryngology at the present time—and indeed he has not attempted this—yet he will be found a safe guide in all conditions and maladies that commonly occur. He nearly always writes from experience, and seldom from authority, and the whole book is expressive of his own personality. The superficial treatment of some subjects rather indicates that he considers them of minor importance, and the book is not one in which to search for information on obscure points or rare diseases, but there are many flashes of wisdom and much practical advice. Not only has the text been improved, but also the illustrations and the general style, so that the new edition deserves a prominent place among the smaller books on these subjects.

### TONIC HARDENING OF THE COLON.

*Tonic Hardening of the Colon*,<sup>3</sup> which forms the subject of a volume by Dr. STACEY WILSON, is a condition which has been well known for several years. It is, however, hardly recognized as a well-defined ailment, and references to it in medical literature are scanty. It leads to a train of symptoms, often of a serious nature, which may be puzzling to the practitioner who is unaware of the underlying cause, and which are readily curable by a simple line of treatment if the true nature of the ailment has been detected in time. Dr. Stacey Wilson has given a full account of the condition from his own long experience, and his book will doubtless be appreciated by general practitioners. The lesion is usually localized to the region of the caecum or sigmoid colon, and consists in a prolonged over-activity of a segment of the colon of the type described by Sherrington as "postural muscular activity." The segment becomes like a hard rubber tube and necessarily causes increased contractile activity of the colon muscles, which in its turn intensifies the reflexes originated by the normal activities of the bowel, producing symptoms having a very wide range. The only certain evidence of the ailment is the presence of abnormal hardening and tenderness, and in the absence of a systematic examination of the colon there is nothing in the symptoms to demonstrate to any medical man the existence of the ailment. The author admits that some may suspect that the disease he describes exists nowhere but in his imagination, and these he advises to palpate the colon in the left iliac fossa in a series of a score or two of cases, and, where hardening is found, look for the symptoms and try the effect of the treatment he describes.

The reflex circulatory disturbances associated with hardening of the colon are shown in such symptoms as lassitude and inability to work and deadness of the fingers from generalized contraction of the arterioles; and a more local effect occurs as swelling and cyanosis of the fingers, such as is seen in Raynaud's disease. In a few cases vasomotor angina pectoris has been met with. The connexion between tonic hardening of the colon and mental symptoms appears to be important, and it is not generally recognized. The author states that it is by no means unusual for a degree of mental depression to arise, of sufficient severity to induce suicidal tendencies, and cases are cited in which treatment of the colon has restored the mental balance in these and other forms of emotional instability. The intimate reflex relationship between the stomach and the colon explains the frequent occurrence of gastric disturbances, of which the most important are pyloric spasm with a certain amount of dilatation, reflex vomiting, and occasionally hardening of the muscles of the stomach, associated with tenderness and severe vomiting. As regards the function of the colon itself, no recognizable disturbance may be present;

constipation, however, is very liable to occur, and at times there may be considerable dilatation above the contracted segment. Other symptoms mentioned are brachial neuralgia, giddiness, and palpitation; and a case is cited in which the pain in the colon appears to have been intensified at the menstrual periods, leading to the diagnosis of dysmenorrhoea, relief being obtained by treatment directed to the colon. The prognosis is, as a rule, good when the condition is recognized early and receives adequate treatment on the simple lines laid down by the author. Where, however, neurasthenia has resulted from the ailment, the outlook may be far from satisfactory.

### ACTINOTHERAPY.

*Actinotherapy for General Practitioners*,<sup>4</sup> by Dr. H. G. FALKNER, bears a strong family resemblance to a number of other works previously published on the same subject. There is a semi-technical introduction dealing with the physics and history of the medical uses of ultra-violet light, which is the only department of actinotherapy dealt with, and a somewhat lengthy section describing the various types of apparatus put on the market by enterprising manufacturers, and copiously illustrated from their catalogues; further on a considerable portion of the book is devoted to an enumeration of the various diseases treated, fortified by cases illustrating the wonderful results obtained. Speaking generally, ultra-violet therapeutists are nothing if not optimists. Perhaps the most interesting and novel parts of the book are the chapters in which Dr. Falkner describes the results he has obtained from tests of the various sorts of goggles on the market as regards their impermeability to ultra-violet and also infra-red radiation, and those in which he shows how lamps fitted with different electrodes vary enormously in their output of ultra-violet rays from time to time. The same pair of electrodes, working apparently under constant conditions, will at one moment produce a copious supply of ultra-violet rays, while within a few minutes the output will fall off to a small fraction of its former quantity. The best and most uniform results, he finds, are given by electrodes made of a substance called "metallium," but the composition of this material is not given. Confidence in Dr. Falkner's electro-physical experiments, however, is not increased by reading the observation which convinced him that ultra-violet light is closely allied to x rays—the observation that his "big raying lamp" (no doubt an extremely powerful illuminant) could throw a shadow of the bones of the hand and forearm on a white wall. It might have been thought that any medical student would have known that this was caused by the fact that the flesh is to a certain extent translucent, while bones are much less so, and the shadow cast by the latter has nothing whatever to do with x rays. Nevertheless, although this book is often open to a certain amount of criticism, its perusal will enable a beginner to get a fair idea of the methods and practice of employing ultra-violet radiations in therapeutics.

### PHARMACOGNOSY.

*Pharmacognosy and Materia Medica*,<sup>5</sup> by H. C. WASHBOURN and W. H. BLOME, is a textbook for students in pharmacy and a handbook for practising pharmacists. One of the authors is a professor of pharmacy and the other is a director of the laboratories of a chemical firm, and hence together they possess a first-hand knowledge of the needs of both the student and the practising pharmacist.

Pharmacognosy is one of the most difficult subjects on which to write a readable textbook, because most of it must necessarily be composed of detailed descriptions of the appearance and characters of plants and drugs. The authors of this volume have reduced their material to manageable dimensions by eliminating descriptions of the

<sup>3</sup> *Tonic Hardening of the Colon*. By T. Stacey Wilson, M.D. and B.Sc. Ed., F.R.C.P. (Lond.). Oxford Medical Publications. London: Milford, Oxford University Press. 1927. (Demy 8vo, pp. xxiii + 210. 8s. 6d. net.)

<sup>4</sup> *Actinotherapy for General Practitioners*. By H. G. Falkner, L.R.C.S.L., L.R.C.P.L., L.M. Rot. Hosp. Dub., O.B.E. London: Baillière, Tindall and Cox. 1927. (Demy 8vo, pp. x + 152; 26 figures. 7s. 6d. net.)  
<sup>5</sup> *Pharmacognosy and Materia Medica*. By Homer C. Washbourn, Ph.C., B.S. (in Phar.), and Walter H. Blome, Ph.C., M.S. With a chapter on Vitamins and one on Insulin by Walter Flitz, M.S. New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1927. (Med. 8vo, pp. ix + 585; 110 figures. 25s. net.)

microscopic characters of drugs, and also by making what they have to say about the physical characters of drugs fairly short and concise. It is profusely illustrated, and contains an account of the history, habitat, properties, and uses of each of the vegetable and animal drugs in the *United States Pharmacopoeia* (tenth edition) and in the *National Formulary* (fifth edition), and of a limited number of other non-official drugs; the total has thus been restricted to a moderate number.

As a result of these restrictions and limitations the authors have been able to produce a very interesting volume, and one that will serve as a handy work of reference in respect to all the more important drugs. In addition to the usual information many interesting scraps of history and descriptions of the methods of cultivation of drugs have been included. The volume concludes with two chapters by Mr. W. Pitt, giving a short account of the vitamins and of insulin.

### AN ECONOMIST ON STIMULUS.

In his Rede Lecture last year at Cambridge, which has recently been published in a small volume, Sir JOSIAH STAMP gave his views on *Stimulus in the Economic Life*<sup>9</sup>; he began by distinguishing stimulus from incentive, and went on to examine the increment in incentive. After describing methods of stimulating capital, and laying down a provisional classification of stimulus according to its results, the author said that "the economic life is a complex reaction between a physical world, obeying the laws of physics and chemistry, and living organisms obeying more elusive biological and physiological principles, the whole relationship being worked upon by individual and mass psychological and 'spiritual' forces." Various stimuli are then passed in review, especially those which have been made the subject of physiological and psychological investigation in labour tasks. Sir Josiah Stamp is doubtful whether Knoepfel's view, that an ideal attained by a piece-worker is automatically replaced by one still higher, is true as a rule. General experience, he says, points to a standard amount of earnings which the worker will exert himself greatly to reach, but will not exert himself greatly to exceed. It is pointed out that the change in the value of money has meant that business enterprise has been unconsciously subsidized by the slow unseen robbery of past accumulations of capital. The fallacy of "the standard of life," "the living wage," and "the motive of adequate profit," in that they are all relative conceptions, is pointed out. Sir Josiah Stamp thinks that while a time of depression is a forcing ground for reorganization and the elimination of non-essentials, prosperity, not necessity, is the mother of invention. He is not convinced, apparently, that the cash nexus is the chief bond between the worker and his work; but he is uncertain whether a new or substituted incentive may be found, or whether, "in an environment with a higher sense of duty, or a different ethical bias, the response to an extra-profit stimulus, or to a higher wage stimulus, may be entirely different."

### NOTES ON BOOKS.

To Sir KENNETH GOADBY has fallen the happy experience of being called on for a third edition of his work on *Diseases of the Gums and Oral Mucous Membrane*<sup>9</sup> within five years of its first publication. The book is the outcome of years of laboratory and clinical work, informed always with the spirit of research, and its popularity is a tribute to the pioneer in dental bacteriology, both as a clinician and as a laboratory worker. In this edition the chapter on general diseases of mouth origin has been recast with good effect, and some fresh cases have been recorded of uncommon affections originating in the same region; the disease, indeed, must be rare which has escaped the author's personal observation. As might be expected, the value of the book lies largely in a constant correlation

of bacteriology with clinical symptoms, but the advice on actual treatment is often of equal value. The author makes an important clinical observation (p. 131) when he says: "Chemical examination of the stomach in cases of chronic oral infection invariably gives a large excess of lactic acid together with a diminution in the normal hydrochloric acid present"; and very justly draws attention to his observation, published in 1911, that slow and progressive joint infections followed injection into rabbits of a special type of mouth streptococcus. The book, however, suffers from serious blemishes. Chapter I should be rewritten—or even cut out; there is a tendency to redundancy, and often the author's style leaves the reader perplexed. Nevertheless, it is a work we can recommend to all interested in mouth conditions.

Why should American babies from the age of 5 months require a special manual of graduated exercises? Most babies one sees here are eager to kick and push and stretch in that delightful interval between the bath and redressing. Apparently Dr. WILKES of the New York Nursery and Child's Hospital does consider that a daily course of systematized exercises would benefit all infants. He has therefore drawn up a series of twelve exercises, and collected them into a book called *Baby's Daily Exercises*.<sup>10</sup> They are very clearly set out and very well illustrated. No doubt such exercises, if carefully and intelligently performed, would increase the infantile musculature. The necessity is a matter of opinion. The author does give warning that "babies who have had kidney trouble should be exercised very cautiously."

The *Minutes of the General Medical Council and of its Various Committees*<sup>11</sup> for the year 1927 have now been published, with twenty-one appendixes, in a volume which includes the customary detailed reports of the two sessions of the General Medical Council and its Executive Committee, and those of the English, Scottish, and Irish Branch Councils. The longest of the appendixes comprises the final report (nearly 200 pages in length) of the Education Committee on the progress made throughout the country towards the readjustment of the medical curriculum in accordance with the resolutions adopted by the Council on May 26th, 1922, which came into force on the first day of the following year. The *General Index* to the minutes of the General Medical Council and of its Executive and Dental Committees, and of its three Branch Councils, from 1903 to 1927, has also been published. It relates to volumes xl to xlv of the *Minutes*. The plan of previous editions has been followed, and each subject is fully indexed, the references being arranged chronologically, with appropriate sub-headings.

<sup>9</sup> *Baby's Daily Exercises*. By Edward Theodore Wilkes, B.S., M.D. New York and London: D. Appleton and Co. 1927. (Sup. roy. 10s. 6d., pp. xi + 77; 14 figures, 4s. 6d. net.)

<sup>11</sup> *Minutes*, 12s.; *Index to Minutes*, 7s. 6d. London: Constable and Co., Ltd. 1928.

### PREPARATIONS AND APPLIANCES.

#### "SEPTICEMINE" AND "IODASEPTINE"

*Septicemine* (Cortial) has the chemical constitution of iodo-benzon-methyl-di-formine and contains 33 per cent. of iodine. It also contains 45 per cent. of formaldehyde in organic combination. This drug is given intravenously; the adult dose is 1 to 2 ampoules. Favourable results have been obtained by French clinicians with this drug in septicæmias of various forms. Vaucher and Uhrig (BRITISH MEDICAL JOURNAL, *Epitome*, January 21st, 1928, para. 63) state that the drug causes no toxic symptoms. The drug is also recommended for a wide variety of acute infectious diseases. It is supplied in ampoules of 4 c.c.m.

*Iodaseptine* (Cortial) has the chemical formula of iodo-benzon-methyl-formine and contains 42 per cent. of iodine. This compound was discovered in 1910 and has been used extensively by French clinicians. The drug can be given by mouth in the form of tablets and can also be injected intramuscularly, or, preferably, intravenously. The intravenous dose is from 0.5 to 2.0 grams in the form of a 10 per cent. solution. The drug has been favourably reported on in the treatment of chronic rheumatism, pulmonary tuberculosis, and syphilis. It is supplied in the form of tablets (0.2 and 0.3 gram) and in ampoules containing 5 c.c.m. of a 10 per cent. solution.

Both drugs are supplied by the Anglo-French Drug Co., Ltd., 238a, Gray's Inn Road, London, W.C.1.

#### CONCENTRATED TETANUS ANTITOXIN-GLOBULINS.

Messrs. Burroughs Wellcome and Co. are now supplying concentrated tetanus antitoxin-globulins containing 2,000 units in each cubic centimetre. Concentration is effected by elimination of proteins of no antitoxic value from the serum. A considerable reduction in volume is secured, and the administration of high unit doses is therefore facilitated. "Wellcome" concentrated tetanus antitoxin-globulins is prepared at the Wellcome Physiological Research Laboratories and is issued by Burroughs Wellcome and Co., Snow Hill Buildings, E.C.1, in phials containing 20,000 international units in 10 c.c.m.

<sup>9</sup> *On Stimulus in the Economic Life*. By Sir Josiah Stamp, G.B.E., Hon. Sec.D., LL.D., F.B.A. London: Cambridge University Press. 1927. (Cr. Evo. pp. 68, 3s. net.)

<sup>10</sup> *Diseases of the Gums and Oral Mucous Membrane*. By Sir Kenneth Goadby, K.B.E., M.R.C.S., L.R.C.P., D.P.H. Cantab. Third edition. London: Oxford University Press. 1928. (6½ x 9½, pp. xvi + 412; 118 figures, 10 plates, 22 2s. net.)

## RADIUM TREATMENT IN DENMARK.

In a paper read before the Danish medical society Medicinsk Selskab, and published in *Ugeskrift for Læger* on January 5th, Dr. E. Collin describes the work of the radium station in Copenhagen during the five-year period April, 1920, to April, 1925, in which a fairly uniform technique was employed: 1,650 patients were treated, of whom 384 were gynaecological cases. Among the non-gynaecological benign new growths there were 285 cases of angioma, 54 of keloid, 67 of callosities, and 159 of warts.

*Superficial Radium Therapy.*

The results in the cases of benign superficial tumours were excellent. Inquiries into the subsequent fate of these patients showed, in the case of angioma, recovery in 80 per cent. and marked improvement in 20 per cent. The corresponding figures for keloid were 37 and 60 per cent. respectively. All the cases of callosities were cured, and 85 per cent. of the warts. In 15 per cent. the patients treated for warts could not be traced. Only 50 per cent. of the patients treated for corns were cured, but the remainder were much improved. Discussing in detail the treatment of angioma, Dr. Collin states that complete recovery could be obtained in almost every case in which the size of the new growth was no larger than that of a walnut. He had found unsuited for radium treatment the perfectly flat naevi, which are more fitted for other methods of treatment, such as freezing, and the pedunculated angioma, which are better treated by excision. On the other hand, the red, or cyanosed, raised, or deep-seated haemangioma of the skin or mucous membrane reacted satisfactorily to radium treatment, which often succeeded after other methods had failed.

Almost all the cases of keloid benefited from radium treatment, the skin becoming flatter and paler and a soft and hardly visible scar being left. At the same time relief from the pain and itching, which often complicates this condition, was obtained. But in a large proportion of cases some trace of the keloid remained, preventing the claim of a complete recovery. While radium treatment was given to the cases of keloid of old standing, with the formation of pale, cartilaginous tissue, the more recent and still pink keloid was found to react satisfactorily to x-ray treatment, which was also available at the radium station. The tender and most troublesome plantar callosities were found to react satisfactorily both to radium and to x-ray treatment, and the successes achieved in this class of case were the more gratifying as many of the patients had been unsuccessfully treated by other methods. Although ordinary warts of the hands disappear as a rule under skilled x-ray treatment, and nearly always under radium treatment, the practice was adopted of passing on these cases to dermatological clinics. The radium station has also paid little attention to corns, for radium treatment is apt not only to be ineffective, but often even injurious, since a periosteal reaction frequently occurs about the bone lying immediately under the corn. But, if other methods of treatment fail, skilled x-ray treatment may be given, since it is often beneficial and does no harm. In a class midway between the benign and malignant new growth Dr. Collin places naevus verrucosus and pigmentosus, which he had found responded most satisfactorily to radium treatment.

*Treatment of Malignant Growths.*

Among the 600 cases of malignant new growths treated in the period under review there were 84 during the first three years in which the disease involved the face or lips, and the subsequent fate of the patient was investigated after an observation period of five to seven years. In practically all these 84 cases the diagnosis of basal-celled carcinoma was verified by a microscopic examination, the exploratory excision for which never did harm. No correlation (such as described by French workers) could be established between the microscopic picture on the one hand and the reaction of the new growth to treatment on the other hand. Many of the patients had previously been operated on once, or more often, or had relapsed after x-ray treat-

ment. It was observed that a carcinoma of the skin which had become resistant after repeated courses of x-ray treatment might well still be sensitive to, and disappear as the result of, a single radium treatment, and it was this observation which induced the Copenhagen radium station to abandon almost completely the x-ray treatment of carcinoma of the skin in favour of radium, except in the small and easily operable cases in which the cancer was excised. There were many patients in whom the disease had become resistant to x rays as the result of skilled or unskilled treatment of this kind elsewhere. With regard to the latter class, Dr. Collin deplores the attempts of x-ray amateurs to tinker with malignant disease. Both x-ray and radium treatment must be in skilled hands if the best results are to be obtained.

In the three-year period 1920 to 1922 recovery was effected in 72 per cent. of the cases of carcinoma of the skin. In 13 per cent. the fate of the patient could not be ascertained, and in 15 per cent. failure to cure the patient was recorded. In every case in this latter class the patients had already undergone protracted x-ray treatment, which in some cases had lasted for years. These patients reached the radium station in a hopeless state, and the lesson to be learnt from them is that when an epithelioma recurs after one, or at most two, x-ray treatments, it should be operated on or given radium treatment. On the other hand, it cannot be regarded as a mistake to give x-ray treatment to a case of cancer of the skin hitherto untreated, but to give one x-ray exposure after another for the same case is a mistake.

*Radium and X-ray Treatment Compared.*

In addition to being successful in cases which have become resistant to the x rays, radium possesses the advantage of leaving, as a rule, a hardly visible scar—a matter of considerable importance in cases of cancer of the face. While the x rays provoke a certain degree of cicatrization and retraction of the tissues treated, the scar formed under treatment with radium is soft and often invisible, being covered by normal-looking skin if the dosage and technique have been correct. Relapses after radium treatment of cancer of the skin are most rare, and when they do occur, they are usually to be found in the margin of the original patch, where they are, in most cases, amenable to treatment. In the overwhelming majority of cases a single radium treatment was sufficient to cure cancer of the lip locally, but in this class of facial cancer the cosmetically successful results were often marred by distant metastases. For this reason the practice has been adopted at the radium station of giving preventive x-ray treatment of the glands in the neighbourhood, and this measure appears already to have reduced the frequency of metastases. Of the 26 cases of cancer of the lip treated in the three-year period under review, 19 could be said to be cured, an observation period of five years having existed in 15 cases, and one of four years in 4 cases. Of the remaining 7 patients, 2 were not traced, and in 5 cases the treatment failed to arrest the disease. Considering that large operation statistics show a recovery rate of only 40 to 50 per cent. in this class of case, these results of treatment with radium must be regarded as encouraging, both from the cosmetic and the functional point of view; it is doubtful whether they could be achieved by other means. In the case of small, strictly limited cancers of the lip it may, indeed, be just as well to excise them as treat them by radiotherapy, but if the growth recurs, it should always be treated with radium, supplemented by preventive x-ray treatment of the local glands.

Much less encouraging were the experiences of the radium station in the case of cancer of the mouth, tongue, larynx, and oesophagus; none of the 8 patients with cancer of the oesophagus who were treated was still alive. As for cancer of the mouth and tongue, local healing, which was apparently complete, was effected in most cases; but in two or three years there was a recurrence of the disease elsewhere. Dr. Collin gave details of a case of inoperable cancer of the tonsil and palate in which four years were added to the life of a man who would otherwise have been prematurely doomed. There were only 32 cases of

cancer of the breast and thorax—that is, cases of recurrence of the disease after an operation for cancer of the breast—treated; all were inoperable from the outset, and terminated fatally. Dr. Collin still recommends combined x-ray and radium treatment as a palliative measure in such cases. Of the 6 cases of cancer of the penis, 2 showed freedom from recurrence after an observation period of three years and one after five years. For such cases, particularly when the patient is young, the best method would seem to be radium treatment of the glans penis, and x-ray treatment of the local glands; x-ray treatment of the tumour of the glans itself would, on the other hand, seem to be of comparatively little value.

Dr. Collin does not detail his gynaecological cases, but he admits that the results achieved with radium might not prove to be as good as those in Sweden, where, with the inclusion of many operable cases, a recovery rate of up to 50 per cent. after an observation period of five years has been claimed. The difference between the two countries in this respect depends on the fact that in Denmark a high proportion of the cases coming to the radium station are already advanced. Dr. Collin ends his paper with an appeal for a systematic and energetic educational campaign in favour of early detection of the disease.

## EPIDEMIOLOGY IN THE LAST HUNDRED YEARS.

### SIR WILLIAM HAMER'S CHADWICK LECTURES.

EPIDEMIOLOGY in England during the last hundred years was the subject of two Chadwick Lectures delivered by Sir WILLIAM HAMER at the House of the British Medical Association on February 16th and 23rd. The chairmen were, respectively, Sir WILLIAM COLLINS and Sir JAMES CRICHTON-BROWNE.

### *The Germ Theory and the Old Epidemiology.*

In his first lecture Sir William Hamer began by remarking that in epidemiology, as in all branches of scientific inquiry, certain periods or "climates" of opinion were successively encountered. Dr. Crookshank had indicated four periods occurring during the last four and a half centuries, each of them marked by different phases of medical thought and observation. In the first of these, which closed with the era of Willis and Sydenham, wide epidemic prevalences were observed and compared generally without resolution into component diseases, and symptoms obviously due to meningitis, encephalitis, and myelitis were described in relation to occurrences that would now be called disease groups. The next period was one in which systems of nosology were based upon symptoms, the symptom groups in question being usually considered as different elements of special epidemic constitutions. The third period, beginning about 1800, was one in which persistent efforts were made to distinguish specific diseases by the findings of morbid anatomy, and the fourth period, from forty years or so ago, was characterized by the distinction of many specific diseases by association with specific organisms. The lecturer dated from about the middle of the nineteenth century—at which time also the General Board of Health was established—the laying of the foundations of a new epidemiology in this country. By 1883 Hirsch could say that epidemiology bore a character quite different from the same science twenty or thirty years earlier, having filled out in proportions and acquired finish to an extraordinary degree. It was about then that Sir William Collins drew attention to the dangers of an excessive zeal for specialism, and to the tendency, even then existing, to lay undue stress upon the germ and neglect the soil. But "the rain descended and the floods came and beat upon the (epidemiological) house." Pasteur's researches focused attention upon germs, and Koch's special technique made its appearance. Those working on bacteriology in the eighties made frequent announcements regarding the compliance of successive newly described organisms with Koch's postulates, until the old epidemiology, like the silk stockings of Sir John Cutler, which were darned with worsted until scarcely any of the original silk remained, almost disappeared from view. But shortly after the opening of the twentieth century the fact came

to be recognized that bacteriology had sown a reasonable allowance of wild oats, and that a halt must be called. It was agreed that bacteriologists had by then outgrown Koch's postulates as Koch himself outgrew them, and that account must be taken of the results of fifty years' patient examination by epidemiologists of the influence of environment, including conditions of cleanliness, space, dryness, pure water and food. All this, with the increasing knowledge of protozoology, filter passers, enzymes, and the recent demonstration of the mutability of bacilli, made it clear that attention must still be concentrated upon the systematic development of a discipline as conceived and exploited by Hirsch. Progress in knowledge of epidemic diseases was seen to be dependent on a unity of opposites, such as the teaching of Sydenham concerning epidemic constitutions, and of Pasteur and Koch concerning the germ theory of disease.

### *The Return to the Hippocratic Method.*

In his second lecture Sir William Hamer further developed his theme under a plea for a return to the Hippocratic method, remarking that Hippocrates had clearly been of opinion that the soil and surroundings as well as the seed required consideration. The lecturer took an illustration from the influenza epidemic of 1918, the official description of the "setting" of which presented a close resemblance to Sydenham's account of epidemic "constitutions" in 1673-75. Sydenham had reiterated that while the bowels, brain, and lungs were successively attacked, the accompanying diarrhoea, stupor, and pneumonia were all merely symptomatic of one "stationary fever," with all the characteristics of influenza. Furthermore, Sydenham's view that the fever or influenza worked more easily and rapidly near the crests of the pandemic waves, and with more difficulty and more slowly in the intervening troughs, had received ample confirmation. One interesting conclusion to which the lecturer had been led in his study of influenza was the toll which it had levied during the last two and a half centuries upon men of marked ability; and in some conspicuous instances the facts were on record that the influenzas of past times had made havoc of the lifework of notable men and women. Influenza, as Daniel Webster had said, was the "crux of epidemiology." It was not merely, as it had long been supposed to be, a pandemic disease, reappearing once or twice in a generation, but it was ever present, now smouldering, and then, every ten, fifteen, or twenty years, hursting into flame. Its great prevalences were specially favoured by war, famine, overcrowding, and free communication with sufferers from the disease in the early stages of their illness. Despite the huge increase in means of communication and traffic during the last one hundred years, coupled with the entire absence of systematic attempts to limit spread of the disease by sufferers in the early stages, the mortality in London from the influenzal group of diseases appeared not to be appreciably greater, in proportion to population, than it was 150 years ago. Great influences for good had been better food and housing, more cleanliness, and the provision of medical and nursing care in serious cases. To these should now be added carefully considered measures for preventing sufferers from coming into contact with others in the early highly infectious stages of the illness. Above all, it should be appreciated that the most extravagant and bizarre efforts made, under the influence of panic, at times of widespread prevalence were as nothing compared with the steady and continued prosecution of a considered campaign against the influenzal group of diseases conducted on epidemiological lines. The records of recent years abundantly bore witness to the fact that field observations and research should have their place as well as observations and research in the laboratory, and that the two sets of findings should be placed alongside one another and co-ordinated. Given such a consummation, it might be surmised that in public health, as in other scientific work, an age of professionalism and specialism would slowly but surely give place to an age in which interest was taken in general principles, as well as in stubborn and irreducible facts. That was a lesson which he who ran might read in the history of epidemiology during the past hundred years.

### A GREAT FLOOD IN 1829.

#### EXPERIENCES OF A SCOTTISH DOCTOR.

Nor for many years has public attention been so directed to the catastrophic ravages of floods as it has been during the last twelve months. More than a year ago the bursting of reservoir dams near Wemyss Bay and in North Wales gave an inkling of what enormous damage can be caused by the sudden loosing of a torrent of water upon a peaceful and unsuspecting country-side. Since then, apart from what might be called in a comparative sense minor visitations in different parts of the country, there have been during recent months the great Mississippi floods, the Fleetwood disaster, and lastly, the tragic overflow of the Thames into many London streets and houses.

It might be of interest, therefore, to make some reference to the tremendous deluge which swept some parts of the north-east corner of Scotland almost one hundred years ago, generally referred to as "The Great Moray Floods." Those who have visited that part of the country—and they must be many, as in these days golf courses and magnificent fishing rivers attract large numbers of holiday makers—will recall this district as a particularly favoured one in respect of weather. It justly boasts of the finest climate in Scotland for dryness and sunshine, claims which are amply substantiated by the wealth of its fruit crops and the almost prodigal splendour of its flower gardens. On to this land of milk and honey, and in the middle of summer, there suddenly descended one of the most extensive and devastating floods ever recorded.

A very complete history of all the circumstances and the widespread damage caused has been handed down by Sir Thomas Dick Lauder, Bt., in a monograph, first published in 1830, entitled *The Great Floods of August 1829 in the Province of Moray and Adjoining Districts*. From the carefully prepared meteorological tables contained in the book it would appear that during the months of May, June, and July, 1829, the heat was unusually great. On the 3rd and 4th of August a deluge of rain fell all over the district; the wind, which previously had been from the west, suddenly changed to a strong blow from the north-east. Between 5 a.m. on August 3rd and 5 a.m. on August 4th a rainfall of  $3\frac{1}{2}$  inches was accurately recorded. The actual fall on the mountain range of the Cairngorms, which dominates this district, must have been far greater. The result was that the rivers Nairn, Findhorn, and Lossie, the Spey, the Deveron, the Don, the Dee, and the North and South Esks broke their bounds and swept all before them—houses, bridges, roads, cultivated lands, were simply wiped off the map. The whole aspect of the country was changed: new river channels were formed, ships were wrecked, harbours were damaged and in some cases irretrievably silted up, so that even at the present day some of the dire effects of this inundation are still visible.

The work of years of steady progress disappeared in one night. Owing to nearly all the bridges being down and to the damaged state of the roads communications for mails and passengers were hopelessly disorganized for a long time afterwards. Whilst the damage to material was enormous, and has been faithfully recorded, it is strange that the author, whose powers of observation were unusually acute, and whose industry was immense, makes no attempt to estimate the total loss of life, which must have been considerable. There was another very heavy fall of rain on the 27th and 28th of the same month, amounting to 2½ inches, but the consequences were not nearly so serious, possibly because the wind held in the west and north instead of backing into the east as on the earlier occasion.

Dick Lauder collected the stories of many eye-witnesses, and the following extracts bearing on the adventures of one of the local doctors seem worthy of repetition.

"On Monday, the 3rd of August, Dr. Brands of Forres was called professionally to the western side of the river. He forded on horseback, and, ere he had crossed the second branch of the stream, he saw the flood coming thundering down. His horse was caught by it; he was compelled to swim; and he had not long touched dry land ere the river had risen 6 feet.

Whilst at dinner at Moy, he observed it branching out into numerous streams. . . .

"At day-break Dr. Brands hurried down to the offices, and ascended the tower to look out from the top. The prospect was awful. The wide waste of waters was only bounded by the rising grounds about Forres, skirting the flooded plain to the south—by those about Dalvey to the west—whilst, towards the north and east, the watery world swept off uninterruptedly into the expanding Firth and the German Ocean. He looked anxiously for the houses of Stripe Side. They were still standing; but the powerful and agitated stream that rolled around them, and between them and the offices, seemed to threaten their speedy destruction. . . .

"All direct communication with the country northward of Moy was cut off by the flood of the burn meeting that of the river, and floating entirely over the bridge; they therefore took their way by the avenue on the south side of the house. At the gate, about 100 yards in front of it, they found the water very deep; but, though their horses were frequently swimming, they managed to get on by keeping the line of the road. At the distance of a mile from Moy, the water became so deep and strong that they were compelled to make for the rising grounds. The lad now left Dr. Brands with the intention of going round by Dalvey, towards Earnhill and Kineorth, whilst the doctor proceeded towards the Bridge of Findhorn, with the hope of getting one of the fishermen's cables. As he was approaching the bridge, he learned that the last of the three arches, that on the west, had fallen the instant before; and, when he got to the brink, the waters were sweeping on, as if it had never been, making the rocks and houses vibrate with a distant and tremulous motion. At the Turnpike House, at the end of the bridge, he was told that all the boats had been swept away. . . .

"From the brow of the bank to the north-east of the toll-house, Dr. Brands commanded a full view of the flooded country from one extremity to the other. The mightiness of the inundation baffled all description. The waters, breaking out from the pass at Conlerrnose, covered Mundole, and swept furiously through the estate of Balnagieith, carrying corn, trees, hedges, and everything along with them, and rolling over the strong embankment lately constructed along the turnpike road by Mr. Leslie. Meanwhile the chief current was playing furiously against the southern approach of the bridge; and, whilst Dr. Brands was looking at it, the usually dry arch, at its farther end, burst with a loud report, its fragments, mixed with water, being blown into the air as if by gunpowder. . . . The row of fishermen's houses, on the right bank, a little below the bridge, were already in one mass of ruin, and the scene of devastation was complete. . . . Looking down on the houses of Waterside, the hamlet of Broom of Moy, and others, the doctor could see nothing but a few roofs peeping from the midst of the inundation, and as there was now no chance of getting a boat he returned towards Moy. In his way thither his mare was compelled to swim for a great way, and she afterwards stuck in the mud where she touched the ground and was nearly drowned."

Perhaps we may remark in conclusion that Dr. Brands was fortunate in having a horse to ride on such a perilous journey rather than having to trust himself to a motor car.

### ROYAL MEDICAL BENEVOLENT FUND.

At a recent meeting of the committee forty cases were considered and £630 voted to thirty-two applicants. The following is a summary of some of the cases relieved.

Widow, aged 56, of L.R.C.P. who died in 1901. Up to 1914 she relied on boarders for her maintenance, but owing to ill health has had to give up this work, and her income is now reduced to about £21 per annum. Lives with an aged father, who needs constant attention. Voted £5 pending further inquiries.

Widow, aged 55, of M.R.C.S. who died in 1905. Apart from an annuity of £30 per annum is dependent on her earnings by needlework. Rent 17s. 6d. a week, but she sublets two rooms for 10s. a week. Voted £26 in quarterly instalments.

L.R.F.P. and S., aged 77, who mostly practised abroad. Since 1921 has not been able to do any work and has now come to the end of her resources. Voted £36 in quarterly instalments.

Daughter, aged 64, of L.S.A. who died in 1873. Earned her living for thirty-five years as governess-companion, and on having to give up this work was persuaded to take paying guests in a small house. On account of failing health she had to ask the last guest to leave, and a friend found her penniless with several small bills owing. The friend raised a small fund to meet immediate needs; this was being disbursed at the rate of 10s. a week, but was almost exhausted. Voted £30 in quarterly instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

## DEATH OF SIR DAWSON WILLIAMS.

EDITOR OF THE "BRITISH MEDICAL JOURNAL," 1898-1928.

WE have to announce, with deep regret in which all our readers will share, that Sir Dawson Williams died suddenly on Monday, February 27th, at his country home near Bourne End, Bucks. It is but a month or two since he retired after thirty years' work as Editor of the *BRITISH MEDICAL JOURNAL*, and only last week we recorded that a fund had been opened for the purpose of recognizing his long and most distinguished services to medical science and the medical profession. What was to have been a testimonial must now take the form of a memorial. Supporters of the fund will like to know that his own wish, on bearing of the proposal, was that the money raised should be used in such a way as would link his name with some object appropriate to his work.

Sir Dawson Williams's health had given concern to his colleagues and intimates for some years past—indeed, ever since the middle of 1920, when a severe and prolonged heart attack incapacitated him for many weeks. Although he continued to shoulder the cares of editorship for seven more years, those around him were aware that the burden was becoming too heavy for his physical strength, and it often seemed that only his indomitable will-power and devotion to the *JOURNAL* kept him going. Nevertheless,

the parting was a wrench. We are thankful to know that the sadness he felt at ending his lifework was relieved by the countless messages of admiration and affection that came to him during the past few months from medical men and women throughout the world. These public and private expressions of regard touched him deeply. In a letter to his closest colleague—the last of many beautiful letters—he wrote: "Few men can have had such ample opportunities as I of knowing the good things their friends could say of them. . . ." All his many friends had hoped that Sir Dawson Williams would have been spared to enjoy a little quiet after long toil. His mind was vigorous up to the end, and only a week before he died he wrote, at our request, the charming note on the *Oxford English Dictionary* which appeared in our last issue.

A full obituary notice will appear in these columns next week. The memoir will include a number of personal tributes from leading members of the profession. The funeral will be at Little Marlow Cemetery to-day (Friday, March 2nd) at 3.30 p.m. A memorial service has been arranged for Monday next, March 5th, at 1.45 p.m., in St. Paneras Church, near the headquarters of the British Medical Association in Tavistock Square.

SATURDAY, MARCH 3RD, 1928.

### LABORATORY METHODS IN DIAGNOSIS.

ALTHOUGH the very proper effort to establish more and more firmly the scientific basis on which the art of medicine rests must inevitably tend to emphasize the academic aspect of medicine, it would be disastrous if this were to bring about any slackening of endeavours along the line of clinical observation. In an address on diagnosis which is published at page 335 of this issue, Dr. Robert Hutchison suggests that as a result of the increased facilities for laboratory and other investigation, which are to some extent intended to apply the findings of academic medicine to practical uses, there is to-day some deterioration in bedside observation as compared with former days. If this indeed be so, it behoves us to be careful, for modern educational demands require an increasing amount of time to be spent in the laboratory, and presumably (unless familiarity is to breed contempt) an increasing attention to laboratory methods.

The question therefore arises, Is there really any reason why laboratory methods, even if multiplied far beyond those in use to-day, should divert attention from the clinical study of disease? The answer is certainly in the negative if only the nature of the information these laboratory methods afford is clearly recognized. On this point, however, there

appears to be a good deal of misapprehension, and even Dr. Hutchison seems perilously near error when he speaks of "laboratory tests and other short cuts to diagnosis" (italics ours), though his whole argument makes it abundantly clear that for him, at least, there can be no such short cuts. Laboratory workers, like other specialists, are apt to be over-enthusiastic about their own branch of work, and to attach undue weight to the information they are able to give; but no laboratory method yet devised can provide a short cut anywhere; on the contrary, it can only put another fact at the clinician's disposal, and so increase the number of data, whose value it is his business to assess in coming to a considered opinion. But laboratory methods do provide facts; and it is here that the clinician is sometimes at fault, for if the laboratory finding is not in harmony with his clinical conception of the case he is apt, especially in his teaching, to draw distinctions between "clinical observation" and "laboratory methods" which are by no means flattering to the latter. This is all wrong; there is no real distinction between the two types of observation.

The fact that a patient has an eosinophilia, a raised blood urea, or a positive Wassermann reaction, is merely a clinical observation which it happens to be more convenient to make in the laboratory; but if we were to take the necessary apparatus to the bedside, such investigations would in no essential way differ from those made, say, with a stethoscope or a thermometer, and the information they give is much of the same order. Viewed in this light laboratory methods merely give additional clinical

facts. Occasionally it may be a fact which dominates all others, but far more often it is one which, fitting into its place with others in the mosaic, helps to complete the diagnostic picture. Sometimes, indeed, the fact is one for which no place can be found, but this should not be made a ground of complaint against laboratory methods; it is merely evidence of our present ignorance. In the early days of the Widal reaction it was sometimes a complaint that the reaction was negative in a clinically clear case of typhoid fever, but the subsequent recognition of the paratyphoid organisms proved the accuracy of the laboratory work; and doubtless much that seems contradictory to-day will be made plain by the knowledge of the future.

It is, however, not to be denied that danger lurks in too great emphasis upon the importance of the laboratory, and it would be an interesting experiment if, during some part of their career, students could be prevented from access to all reports from special departments, and were made to rely entirely on their own investigations. For some minds there is a curious attraction about facts elicited from a test tube or by the microscope, as being more scientific than those observed by the unaided senses, and this is a prolific source of error. The sensible plan seems to be to collect all the facts that are within our reach by whatever means they are obtained, and then, taking Dr. Hutchison's wise words to heart, pray that we may be granted the supreme diagnostic gift—a right judgement in all things.

### LIGHT THERAPY AND IMMUNITY.

THE beneficial effects of light therapy have been so clearly defined with regard to growth and nutrition that this aspect of the subject has naturally received more recognition than has been accorded to the almost equally promising effects of radiation in another province of medicine—namely, resistance to microbic infection. Not to explore this field would certainly be an example of neglecting the obvious, because there is surely no axiom of hygiene to which assent would be given with more unanimity than to an acknowledgement of the invigorating action of sunlight, particularly in convalescence from infectious disease. Like many other familiar things, however, this recuperating action of sunlight is difficult to investigate by quantitative scientific methods and to define in scientific language. It is generally believed that here, as also with growth and nutrition, it is the ultra-violet rays which are the most effective, but there is little reason to suppose that increased resistance to infectious disease is due to the bactericidal powers of the rays themselves.

Although the ultra-violet rays are so effective in sterilizing bacterial cultures and protozoa in test tubes, they do not penetrate sufficiently to exert a lethal action on microbes in the body. The good results obtained in the treatment of lupus with ultra-violet rays are not to be ascribed to a local disinfecting action of the light on the tubercle bacilli, as was formerly supposed, but rather to a general increase of resistance. It would be a great advantage if we could define more exactly what is meant by a general increased resistance, a state apparently analogous to the natural immunity acquired on recovery from an infectious disease such as enteric fever. Since the labours of immunologists have reaped such a rich harvest in the investigation of the serological reactions of enteric fever, with the discovery of agglutinins, precipitins, complement-fixing antibodies, and so on, it was

natural that in the study of increased microbic resistance after radiation the immunity reactions of the blood should receive a thorough investigation. Gain quickly came from this—and so far, we are relieved to say, without any addition to immunological vocabulary. The test which has proved most useful has been the study of the bactericidal power of the blood, a test designed to express in quantitative terms the property of actually killing or preventing the growth of cocci and bacilli when incubated with a sample of blood.

Ultra-violet radiation has an easily determined action on the bactericidal power of the blood, but the effect of radiation is not necessarily to enhance the bactericidal property. In fact, Gonce and Kassowitz<sup>1</sup> have proved that daily quartz lamp treatment over a period of two to eleven weeks—avoiding any marked erythema, and general, febrile, or focal reactions—does not as a rule improve, but actually tends to lower, the destroying power of the blood for certain test bacteria, such as staphylococci and *B. coli*. In some of these cases, however, the bactericidal power of the blood was substantially raised; and, since we may assume that it is an advantage to raise and injurious to lower the bactericidal power of the blood, it seems obvious that some of their patients were benefited and others injured by the radiation. This conclusion is supported by their records, and finds its explanation in experimental work carried out lately in this country by Colebrook, Fleming, Maitland, and others.

The increased bactericidal power of the blood found in some cases after radiation is not due to any change in the fluids, as proved by the fact that when serum has separated from blood known to be powerfully bactericidal this serum provides an excellent culture medium for bacteria. The bactericidal power of the blood appears to depend on the cells and not the fluids of the blood; in fact, it bears a direct relationship to the number of phagocytes per cubic millimetre. The actual amount of phagocytosis undertaken by any single cell is neither increased nor diminished by radiation; the altered property is due to increase or decrease in circulating phagocytes. This being so it becomes important to consider in greater detail what effect radiation has upon the leucocyte count of the blood. Some years ago this question was investigated by J. H. Clark,<sup>2</sup> who found that ultra-violet rays shorter than 3,000 Angström units induced a great increase of lymphocytes, while the polymorphs remained constant; on the other hand, the near ultra-violet rays, just below the visible portion of the spectrum, had a depressing effect on the lymphocytes and gave rise to an increase in neutrophils lasting only a few hours and followed by an abnormal decrease. Other observers have found that the total white count fluctuates a great deal in any individual after exposure to ultra-violet rays, but the fluctuation varies in different persons, and even in the same person, after repeated exposures to light. Gonce and Kassowitz<sup>3</sup> found that differential counts made at the seventh hour after irradiation showed a relative and absolute increase in the polymorphs, and a relative and sometimes an absolute decrease in the mononuclear cells. By the end of twenty-four hours the total and differential counts usually returned to the same level as had existed before the first exposure. They found an improvement in the bactericidal power of the sample of blood taken at the height of leucocytosis.

If this work is confirmed by other investigators, it

<sup>1</sup> *Journ. Amer. Med. Assoc.*, January 28th, 1928, pp. 280-284.

<sup>2</sup> *Amer. Journ. of Hygiene*, 1, 39, January, 1921.

<sup>3</sup> *Loc. cit.*

will prove that, as far as the bactericidal power of the blood is concerned, the immediate effect of ultra-violet radiation has a direct relationship to the number and character of the leucocytes of the blood. Whether or not the lowered bactericidal power observed in the blood of the majority of their patients after radiation was due to a leucopenia is a question the authors do not attempt to answer. But one other practical point of importance mentioned in this paper deserves emphasis—namely, that the bactericidal power cannot be inferred directly from the number of leucocytes per cubic millimetre of circulating blood, because the phagocytic capacity varies considerably in different individuals, although the antibacterial function of a single white cell may be constant for one individual.

In a recent discussion on ultra-violet radiation therapy at the Medical Society of London (reported in our issue of February 18th at page 259), one speaker, referring to the abuses of ultra-violet ray therapy, classified these under three heads: "Extravagant claims, injudicious doses, and home use." The study of the bactericidal power of the blood has shown how important is the question of correct dosage and proper control of treatment. Having been reminded of the inherent dangers of this valuable remedy, we are glad to recall here that the attitude of the medical profession towards the employment of ultra-violet ray treatment and other forms of electrotherapy carried out by unqualified persons has recently been before the Council of the British Medical Association, and that the matter has been referred to the Science and the Ethical Committees for consideration and report.

#### ETHYL PETROL.

SIR WILLIAM POPE, professor of chemistry in the University of Cambridge, in a letter to the *Times* on February 22nd, has called public attention to the possible dangers attending the use of ethyl petrol. His views have been supported by Dr. H. B. Baker, president of the Chemical Society, in a letter in the same newspaper of February 25th, and one result has been a question in the House of Commons to the Home Secretary, which elicited the fact that the responsibility in this matter rested with the Ministry of Health and not with the Home Office, but that the latter "has been following closely the investigations which have been carried out in the United States." We have already discussed the possible dangers of tetra-ethyl lead as an addition to petrol (February 27th, 1925, p. 273, and January 14th, 1928, pp. 61 and 64), but in view of the great importance of this question we have thought it well to give a summary elsewhere (p. 367) of the investigations to which the Home Secretary has referred. These investigations have led to the conclusion that the use of ethyl petrol (or ethyl gasoline, as it is called in America) has not given rise to toxic symptoms. We would point out, however, that the conclusions of the committee appointed by the Surgeon-General of the United States Public Health Service carry considerably more weight than do the conclusions of the other investigators; and that the committee emphasized strongly the need for further investigation. The necessity for continued investigation appears to us to be obvious. There is no doubt that tetra-ethyl lead is an exceptionally dangerous volatile compound of lead, and lead is the most insidious cumulative poison known to medical science. The evidence available shows that tetra-ethyl lead, diluted in the form of ethyl petrol, has been used for a comparatively short time without any obvious toxic effects being produced. This is a very fortunate occurrence, but it would be foolish to assume that the continued and extensive use of this mixture will of necessity be free from all danger. Sir William Pope indicates

some of the possible dangers that may arise when familiarity breeds contempt and carelessness, and we would strongly support his demand that the Ministry of Health should organize an exhaustive official inquiry. We have no reason to distrust the findings of the American committees of investigation, but the detection of incipient lead poisoning is a very difficult task. In the case of any scientific discovery of importance it is usual to check the results by independent investigations, and surely this ought to be done when the safety of a large section of the community depends on the soundness of the conclusions. Moreover, if it be assumed that the conclusions in question are absolutely correct, the need still remains for a careful watch to be kept lest new dangers arise. This is particularly necessary because lead is a cumulative poison, and, unless the first signs of poisoning are detected, great damage may be done to the health of the community before the effects are obvious enough to arouse public alarm.

#### EVOLUTION OF RECEPTION ORDERS FOR MENTAL PATIENTS.

Dr. J. R. LORD, late president of the Royal Medico-Psychological Association, has written an interesting historical account of the evolution of the reception orders for mental patients in England and Wales, in which he describes the very important part played by Lord Shaftesbury in lunacy legislation during the middle of the nineteenth century.<sup>1</sup> Lord Shaftesbury's attitude towards the question of judicial intervention in the process of certification of mentally deranged persons has often been misunderstood. Dr. Lord, in the course of his examination of the various lunacy enactments of that time and of Lord Shaftesbury's share in them, is careful to dispel this misunderstanding. He shows that only one motive actuated Lord Shaftesbury—the resolve to procure early and efficient treatment for the mentally afflicted. It was this that caused him, on the one hand, to press for the intervention of the justice in rate-aided cases—for without such intervention such cases would be immured in workhouses and be deprived of the advantages of institutions specially designed for the treatment of the insane—and, on the other hand, to oppose strenuously the justice's intervention in private cases, because this could only result in inducing people to keep back the patient as long as they could before they submitted him to treatment in a mental hospital. The value of the intervention of the justice in the process of certification of cases of mental disorder has been challenged many times since Lord Shaftesbury's day, and not solely in the case of private patients, but in rate-aided cases too, on the ground that it is now an anachronism. The recent Royal Commission on Lunacy came to the conclusion that the intervention of the judicial authority is still a necessity, even in the case of the Provisional Treatment Order, whose adoption they recommend. The Commission took care to point out that the value of such intervention depended ultimately on the methods pursued; but even so, it is difficult to escape from the validity of Lord Shaftesbury's observations in his answers to the questions put to him at the Dillwyn Select Committee of 1877. These observations are most apposite to-day. "Just consider it this way," he said. "Supposing you called in the intervention of the magistrate, he must act either ministerially or judicially: if he acts ministerially what earthly use is he? He merely signs his name to the documents . . . it is a mere ministerial act and affords no security whatever. Supposing, on the other hand, he acts judicially and is called to sit in judgement on the certificate, and then signs his name at the foot of the document and says it is

<sup>1</sup> *The Evolution of the Reception Orders for Mental Patients in England and Wales: A Historical Survey.* Reprinted from the *Journal of Mental Science*, October, 1927. London: Adlard and Son, Ltd.

good and sound, he exonerates the medical man from his great responsibility: he exonerates the man who signs the order: he exonerates the man who admits the patient into the asylum because he has declared everything to be good and current: however bad it may be it is endorsed by the judicial man who has been called in by Act of Parliament to sit in judgement on that certificate." "We should object," he says elsewhere, "to an inexperienced layman taking upon himself to reverse the decision of the medical man." Dr. Lord is confident that in the changed circumstances of to-day Lord Shaftesbury, if he were alive, would feel that judicial intervention in the certification of the poor insane was no longer necessary, but to be condemned for the same reason as he condemned it in regard to the private insane—namely, that it delayed early and effective treatment.

#### A CRITICISM OF "B.C.G."

THE results claimed by Calmette and his co-workers for prophylactic vaccination against tuberculosis by means of the "Bacille Calmette-Guérin" vaccine (B.C.G.) have already been criticized by certain observers, mainly from the statistical point of view, and in reply it has been urged that the good results were so obvious to clinicians that statistical difficulties could be ignored. A recent paper by A. Wallgren,<sup>1</sup> who is in charge of the medical side of the Children's Hospital at Göteborg, contains so careful an analysis of Calmette's published conclusions that the criticisms in it cannot be so easily met by such a generalization. He first deals with the oral route chosen for the administration of the vaccine, casts grave doubts upon the amount of absorption likely to occur, and remarks that Calmette himself prefers the intravenous or subcutaneous route for the prophylactic vaccination of animals. The next point made is that following the infection of children by the tubercle bacillus which is survived a state of immunity develops; the sole clinical mode of estimating this immunity at the present time is the tuberculin test. Children who show no reaction to tuberculin are regarded as possessing no specific immunity, and yet according to Calmette's figures only 6 per cent. of infants vaccinated by B.C.G. give a positive reaction with tuberculin. So far Wallgren's criticisms have been on controversial ground, but he is more destructive when he gives a detailed analysis of Calmette's published work. As a basis for estimating the results of vaccination Calmette takes figures which show that of 1,364 infants born of tuberculous mothers in France in 1922, 24 per cent. died during the first year of life "from affections presumed tuberculous." A further inquiry in Belgium in regard to infants born of tuberculous mothers and brought up in contact with them gave the slightly lower mortality rate of 20 per cent. Against these basic figures Calmette brings forward a group of children numbering 1,317 who, up to January, 1926, had been vaccinated with B.C.G., and he states that only 1.8 per cent. of these children exposed to tuberculous infection died of the disease. But when the 1,317 cases are more closely analysed it appears that 564 had been protected for over a year, and of these only 231 had been in contact with tuberculosis. Since among this group of 564 infants 45 are dead, it may be argued that if this mortality is distributed among those 231 in contact with tuberculosis the rate becomes 20 per cent.—the basic figure for comparison. This juggling with the figures is, of course, pushing matters to an extreme, but Wallgren's point is rather that the tables published by Calmette do not contain evidence which puts such adjustments out of court. Dealing still with these 1,317 cases, Wallgren goes on to show that some 96 infants are stated to have died of non-tuberculous diseases, but no necropsies were held, and in the list of causes of death in this group, based on clinical

diagnosis, the largest mortality group is labelled "congenital weakness." May not, he asks, tuberculous infection cause death from congenital weakness or provoke the fatal issue in infants debilitated for other reasons? The other causes of death, such as gastro-enteritis, influenzal bronchopneumonia, and athrepsia, may all be attributed to some tuberculous origin unless this is negated quite definitely by necropsy. These are but some of the questions which Wallgren raises, and it is clear that much more detailed information is necessary, especially of the mortality rates of vaccinated children brought up in contact with tuberculous mothers, before the optimistic claims of Calmette can be completely accepted.

#### THE DEPOPULATION OF MELANESIA.

In an interesting study on the depopulation of the New Hebrides and other parts of Melanesia,<sup>1</sup> Dr. P. A. Buxton points out that remains of vanished peoples are to be found in several parts of the Pacific. Thus, a race of sculptors, now extinct, once flourished on Easter Islands, while in the Caroline Archipelago there were cyclopean builders of whom even less is known. Who these people were and how they lived is a mystery. In other races in the Pacific, however, the decline in population is of more recent date, while in some—such as the natives of the New Hebrides—the decrease is still in progress, and may be studied to-day. It is among these people that Dr. Buxton, while on an expedition of the London School of Hygiene and Tropical Medicine in 1924-25, has made his investigations. He shows how the inhabitants of Melanesia in general, and of the New Hebrides in particular, are now dying out, and among the causes of this he includes constant wars, the practice of magic, insanitary housing, improper infant feeding, the treatment of women under the prevailing gerontocracy, and the prevalence of abortion, infanticide and other customs which have prevailed from time immemorial. These conditions cannot, therefore, be held directly responsible for the depopulation, since this has only set in during the last century. Here it may be noted that it was not until the early years of the nineteenth century that contact with the foreigner became frequent. Not only did constant bloodshed then ensue, but diseases hitherto unknown, and against which the natives had acquired no immunity, were introduced, and began to decimate them, measles alone carrying off thousands. Many writers also assert that syphilis was introduced by Europeans, and that it is largely to blame for the dying out of the natives. Buxton, however, contests this view, and maintains that the disease in question is yaws, or framboesia, which is very prevalent throughout the islands. The "blackbirding" which was among the horrors connected with the sandalwood traffic was an important factor in the depopulation, but Buxton considers that the greatest of all the curses inflicted on the islands by Europeans was the labour traffic, which began about 1850. For many years, and often by force or fraud, natives were carried away to work in the plantations of Fiji, Queensland, Samoa, and New Caledonia, and even in the mines of western South America, many of whom never saw their native country again. That these practices were eventually suppressed can be placed to the credit of the Presbyterian missionaries, who, however, as Rivers pointed out, were also partly responsible for the decay of the population, inasmuch as they rapidly destroyed the communal life and interests of the natives, while putting next to nothing in the place of what they had destroyed. Further, the form of government of the New Hebrides, a joint administration by Great Britain and France, established in 1906, is not conducive to the introduction of reforms or even to rapid and decisive administration, so that the suppression of abuses is apt to be neglected.

<sup>1</sup> *Acta Paediatrica*, 1927, vii, 120.

<sup>1</sup> *Transactions of the Royal Society of Tropical Medicine and Hygiene*, vol. xix, No. 8.

Among the endemic diseases malaria, and especially yaws, and among the imported diseases dysentery, tuberculosis, and other pulmonary diseases, are important factors in depopulation. Apart from these causes, Buxton considers that two very disquieting facts are, first, that though the rate of decline of the population is now less than it was half a century ago, the race continues to die out, irrespective of the abolition of "blackbirding" and the reduction in the severity of epidemics; and secondly, in all parts of the islands about 118 males are born per 100 females, this disproportion persisting through life.

#### CHOLERA BACTERIOPHAGES.

A PRELIMINARY report of work carried out by the Cholera Bacteriophage Inquiry under the Indian Research Fund Association in 1927 has recently been submitted by Dr. F. d'Herelle of the Pasteur Institute, Paris, and Major R. H. Malone, I.M.S., of the Central Research Institute, Kasauli.<sup>1</sup> The authors first studied in detail twenty-three cholera patients who were undergoing treatment at the Campbell Hospital, Calcutta, during the period April 27th to June 20th, and they made the following observations. In three cases no bacteriophage was present on admission, and all the cases proved fatal within twenty-four hours. Dr. d'Herelle recalls that in 1921, while in Indo-China, he failed to isolate bacteriophages in 100 fatal cases of cholera. In another three of the Calcutta cases the bacteriophage was weak from the start, became weaker, and finally disappeared; these cases proved fatal within twenty-four hours after disappearance of the bacteriophage. In two cases where the bacteriophage was strong on admission recovery was prompt. In two other cases the power of the bacteriophage fluctuated, but finally became potent, and there was delayed recovery in each case. In the majority of the cases (thirteen out of twenty-three) the virulence of the bacteriophage towards the cholera vibrio was feeble at first, but became exalted and attained its maximum potency in twenty-four to forty-eight hours after the onset of the disease. The authors conclude that recovery or death from an attack of cholera depends upon the presence and behaviour of the bacteriophages. They found that intravenous saline injections were helpful in prolonging life and giving the bacteriophage time to reach the necessary exaltation in virulence; in the six cases where the bacteriophage was absent the injections were of no avail. Moreover, it was proved that, while the inherent power to attack vibrios varied in different races of bacteriophages, this power could be raised, and the authors were able, by means of passage through other patients, to raise the potency of even the two strongest strains in their series of twenty-three cases. With these exalted bacteriophages the investigators then proceeded to treat a number of cholera patients in four villages where outbreaks of the disease had not long started. Altogether, in the four villages forty-one patients were treated with bacteriophages; and only three, or 7.3 per cent., of these died; in the same villages 107 patients were untreated with bacteriophage, and of these 70, or 65.4 per cent., died. Prompt notification of an outbreak of cholera in a fifth village (Nawar) afforded the authors an opportunity of testing the prophylactic powers of cholera bacteriophages. In this village, consisting of 345 houses mainly occupied by Jats, the water supply is derived from thirteen public and nine private wells. Six cases of cholera occurred on August 2nd, of which three proved fatal, while six further cases with two deaths occurred next day. On August 4th 30 c.c. of a culture of selected bacteriophage were added to each of the two wells supplying the contaminated area. No fresh case was reported after this "salting" of the water, and the Jat patients who

drank of these wells recovered. The authors recognize that the evidence of this single experiment is not of much value; but Dr. d'Herelle refers to his more extensive experiments in fowl typhoid, where in each case the epizootic ceased immediately after spreading the bacteriophage in the environment. It certainly seems reasonable to suppose, with the authors, that greater success should follow when auxiliary bacteriophages of proved anticholera virulence and in sufficient quantity are, so to speak, rushed up to the support of exposed persons at the very beginning of an epidemic, than when, in the natural course of events, valuable time is lost before the first convalescents begin to pass in their stools potent bacteriophages which then (like the vibrios themselves) become disseminated by flies and drinking water. Still more reason is there to expect that the use of highly virulent bacteriophage cultures should prove helpful in the treatment of these patients who, on their own account, produce no bacteriophage, or at best only a feeble and evanescent one. The results of further experiment in both directions will therefore be awaited with great interest, and should these confirm those already reported a rational and practical expedient will be available for the control of cholera epidemics and the care of cholera patients.

#### SPORTS DOCTORS.

THERE have been and are in this country surgeons with special experience in the diagnosis and treatment of injuries incurred in the pursuit of various sports, but no attempt has as yet been made to develop the study of these injuries into a specialty. In Germany, however, where things are apt to be taken more seriously, Professor Dr. Hermann Altmann of Leipzig has produced a work<sup>1</sup> which treats systematically of most sports and bodily exercises, and of their medical and surgical aspects. His plan is to print an article by a specialist in each sport and to follow it by another dealing with its medical aspects. Thus there is an article on rowing, which goes into a good many details as to boats and the weights of members of crews, etc., written by Dr. Altmann himself. This is followed by another on the tactics of rowing matches by Olympia Master Hermann Wilker, and, to complete the subject, one on the medical aspects of rowing by Dr. Rolf Friedländer of Berlin. Dr. Altmann thinks that a "Sportarzt" is not properly equipped to treat sportsmen unless he possesses at least a theoretical knowledge of those games and sports with which they amuse or occupy themselves. Professor Bier of Berlin, in an introduction, supports Dr. Altmann, and urges that every medical man who wishes to use sports as therapeutic measures should say to himself that to do so he must correspondingly have exercised his body and have got an insight into the means of physical exercise. Before the last decade of the nineteenth century Germany trusted to implement gymnastics as taught in gymnasiums for exercise, but after that time an interest sprang up in games as practised in England and America. The German sport authority (Behörde) for athletics was founded in 1897, a society analogous to our Amateur Athletic Association. There is a great deal of interest to us in the medical part of the introductory article on "Leichtathletik" (a convenient term which includes most of the sports practised here at such meetings as those of Oxford and Cambridge). It is interesting to note that Dr. Arno Arnold of Leipzig quotes Dr. Parkes Weber's account of the thrombosis of the inferior vena cava from which the late Dr. Rivers Pollock suffered at the end of a hurdle race. He appends to his article an elaborate form to be used by surgeons in the examination of athletes and would-be athletes, as used by the German High School for Bodily Exercises. If this is conscientiously filled up there can be little left to be known about the habits and physique

<sup>1</sup> *Indian Medical Gazette*, 1927, lxii, No. 11, p. 614-616.

<sup>1</sup> *Kleine Sportskunde*. Unter Mitarbeit von fachgenossen herausgegeben. Leipzig: G. Thieme. 1928. (M.9.50.)

of the subject of it. Association football is very shortly described, and Rugby barely mentioned. Boxing, wrestling, mountaineering, skating, ski-ing, cycling, and even flying receive due attention, as well as almost every other kind of sport. Swimming is dealt with at some length, but golf and cricket get scarcely more notice than do croquet and bowls. These four are lumped together as "turf games," but Mr. Ernest Glass of Hamburg welcomes the spread in Germany of golf.

#### IMPRESSIONS OF AMERICAN UNIVERSITIES.

For three months in the early part of 1926 Dr. Edwin Deller—the academic registrar of the University of London—was the guest of the Laura Spelman Rockefeller Memorial in order that he might quietly and informally investigate and discuss educational problems in the universities in various parts of America, and now with a winning consciousness of his "infirmities" he has placed his impressions on record in an interesting pamphlet.<sup>1</sup> In the first place, he was struck by the keenness of the American belief in education, which is shown in the practical way of the exemption of universities from national and local taxation. The ideal of the American university has been built up out of the British tradition of "sound learning," the German spirit of research, and the American conception of even broader service to the community in the way of producing good citizens. But here Dr. Deller raises the question of the danger of making utility rather than intellectual training the object of university education. In British medicine instruction has been mainly ancillary to hospital work, whereas in Germany the university has for many years been the predominant partner in the combination with the hospital. In America both the relations may be seen, respectively, in the case of the Mayo Clinic attached to the University of Minnesota and the Rockefeller Institute and Hospital in New York. The strongest feature of the American university appears to be the provision for post-graduate instruction, and in some States the activities of the universities have made them the most esteemed governmental organs; this is due in part to the relatively undeveloped condition of the other State organs and the low opinion in which legislators and "politics" are held. Some of the American universities are extremely well provided with money, but all have their difficulties, especially in maintaining a high standard of education for the appalling number of students, often very inadequately prepared, and who, their teachers say, are often without any very clear objective, except to get on in a land where material success is too prone to be regarded as the ultimate good.

#### SIR CHARLES HASTINGS LECTURE.

THE second of the Popular Lectures instituted by the British Medical Association, and associated with the name of its founder, Sir Charles Hastings, will be given by Sir George Newman, K.C.B., Chief Medical Officer of the Ministry of Health and the Board of Education, on the evening of Wednesday, March 21st. Sir George Newman has chosen as the title of his lecture "The fundamentals of health." It will be delivered in the Great Hall of the British Medical Association's House in London, and the chair will be taken at 8 o'clock by Lord Cozens-Hardy. The first Hastings Lecture was given a year ago by Sir Berkeley Moynihan, President of the Royal College of Surgeons of England, on "Cancer and how to fight it," and it attracted widespread public interest. Admission is free by tickets obtainable from the Financial Secretary, B.M.A. House, Tavistock Square, W.C.1. Seats not occupied by ticket holders by 7.50 p.m. will be available for other members of the public.

## TETRA-ETHYL LEAD AS AN ADDITION TO PETROL.

### INVESTIGATIONS IN THE UNITED STATES.

AN American correspondent has suggested to us that in recent articles in the *BRITISH MEDICAL JOURNAL* on the possible dangers of ethyl petrol sufficient weight was not given to the negative conclusions arrived at by certain committees who have investigated the effects produced by this substance. The matter is of such great potential importance that we think it advisable to give our readers a somewhat fuller summary of the evidence available.

Two separate committees in the United States have investigated the effects produced by ethyl petrol. The first investigation was carried out by the Bureau of Mines, who entered into an agreement in October, 1923, with the General Motors Research Corporation of Dayton, Ohio, according to which the corporation paid the expenses of a research by the Bureau into the effects produced by exposure to the exhaust fumes of engines using ethyl petrol. The Bureau first investigated the effects on animals of exposure to the exhaust of an engine using ethyl petrol of normal constitution (that is, one part tetra-ethyl lead in 1,270 parts by volume of petrol). They concluded that

"the effects of exposure to the concentration of lead prevailing in the air during this campaign were not manifested by the storage of lead, pathology, haematology, symptoms, weight, and growth of the animals exposed."

They next investigated the effects of exposure of animals to the exhaust of engines using five times the commercial concentration of tetra-ethyl lead. In this case "distinct storage of lead was found in all species and groups of animals exposed during campaign 2," but "no characteristic symptoms of lead poisoning were obtained, except loss of weight in some animals." Upon the basis of these results the Bureau of Mines published a preliminary report in the autumn of 1924<sup>2</sup> recording these negative findings.

About this time, however, various things happened. Eldridge<sup>3</sup> published a report from the Chemical Warfare Service showing that daily application to the skin of a dog of 0.1 c.cm. per kilo of pure tetra-ethyl lead produced lethal results. This association of tetra-ethyl lead with gas warfare was alarming, and the alarm was increased by the occurrence of fatalities in the factories making tetra-ethyl lead. Hamilton, Reznikoff, and Burnham<sup>4</sup> in 1925 recorded eleven such fatalities in the previous seventeen months. They also criticized severely the experimental methods and conclusions of the Bureau of Mines.

In May, 1925, the Surgeon-General, U.S.A., appointed a strong committee to investigate the toxicity of ethyl petrol ("ethyl gasoline" is the American name), and the production of ethyl petrol was suspended until the committee reported. This committee reported in January, 1926,<sup>5</sup> after eight months' work. Meanwhile the Bureau of Mines continued their work for another year. They examined the effects of exposing animals to the vapour of unconsumed ethyl petrol, and also studied the effects of applying ethyl petrol to the skin. When animals were exposed to the vapour of commercial ethyl petrol they found no evidence of storage of lead, and also found that "the weight and growth of the animals were normal, which included those born on test." With ethyl gasoline containing two and a half to five times the normal content of tetra-ethyl lead they found: "Some of the animals exposed to 0.10 per cent. ethyl gasoline vapour showed distinct storage of lead," but also "no inhibition of growth or loss of weight was noted to occur in animals exposed to 0.1 and 0.5 per cent. ethyl gasoline vapours." When ethyl gasoline was applied to the skin they found that

"ethyl gasoline containing the commercial amount of ethyl fluid (1 in 1,270), applied daily in doses up to 1 c.cm., when it is limited to skin absorption is apparently no more injurious than straight gasoline."

This work was apparently finished in December, 1925, but for some reason or other the full report was not published until 1927. The report consists of a stout volume of 447 pages. Meanwhile the report of the Surgeon-

General's Committee was published in January, 1926. The committee examined transport and garage workers who had been working with ethyl petrol for two years. In view of the importance of their conclusions we reprint them in extenso.

"On the basis of this investigation the committee feels that the following general conclusions are justified:

"1. Drivers of cars using ethyl gasoline as a fuel, and in which the concentration of tetra-ethyl lead was not greater than 1 part in 1,500 parts by volume of gasoline, showed no definite signs of lead absorption after periods approximating two years.

"2. Employees of garages engaged in the handling and repairing of automobiles, and employees of automobile service stations, may show evidence of lead absorption and storage, as indicated by the lead content of the faeces and the appearance of stippled cells in the blood. In garages and stations in which ethyl gasoline was used the amount of apparent absorption and storage was somewhat increased, but the effect was slight in comparison with that shown by workers in other industries when there was a severe lead hazard (Group E), and for the periods of exposure studied was not sufficient to produce detectable symptoms of lead poisoning.

"3. In the regions in which ethyl gasoline has been used to the greatest extent as a motor fuel for a period of between two and three years no definite cases have been discovered of recognizable lead poisoning or other disease resulting from the use of ethyl gasoline.

"In view of these conclusions your committee begs to report that in their opinion there are at present no good grounds for prohibiting the use of ethyl gasoline of the concentration specified as a motor fuel, provided that its distribution and use are controlled by proper regulations."

A very important qualification is, however, appended to these conclusions:

"In conclusion we beg to say that we are conscious of the fact that the conclusions to which we have come in this report, although based upon most careful and conscientious investigations, are subject to the criticism that they have been derived from the study of a relatively small number of individuals who were exposed to the effects of ethyl gasoline for a period of time comparatively brief when we consider the possibilities in connexion with lead poisoning. A more extensive study was not possible on account of the limited time. It remains possible that if the use of leaded gasolines becomes widespread conditions may arise very different from those studied by us, which would render its use more of a hazard than would appear to be the case from this investigation. Longer experience may show that even such slight storage of lead as was observed in these studies may lead eventually in susceptible individuals to recognizable lead poisoning or to chronic degenerative diseases of a less obvious character. In view of such possibilities the committee feel that the investigation begun under their direction must not be allowed to lapse."

Another piece of evidence is an unpublished paper courteously forwarded to us by Dr. R. A. Kehoe.<sup>6</sup> This work was done between October, 1926, and April, 1927. The authors examined 143 persons who had been exposed to ethyl petrol as garage mechanics, filling station attendants, or tank wagon employees, and 69 persons doing similar work with ordinary petrol. About 40 per cent. of the cases had been exposed to ethyl petrol for more than a year, and 16 per cent. had been exposed for more than three years. The cases were examined carefully for signs of lead excretion and for lead poisoning. The authors conclude:

"On the basis of this study it is possible to state conclusively that there is no evidence to indicate that appreciable lead absorption has occurred in the case of persons who have had the maximum exposure up to the present to the hypothetical hazards associated with the distribution and handling of ethyl gasoline. On the other hand, evidences have been found that the methods of study are sufficiently sensitive and accurate to discover signs of lead absorption, if this had occurred."

This we believe to be a fair summary of the evidence at present available regarding the possible dangers associated with the use of ethyl petrol. The value of the evidence is, of course, very difficult to assess exactly. It depends upon the accuracy of very delicate technique—for example, the estimations of fractions of a milligram of lead in the excreta and the estimation of slight deviations from normal of the red blood corpuscles. Furthermore, important questions arise regarding the intensity and the duration of the exposure to ethyl petrol, and also regarding the possibility of individual variations in susceptibility to lead

poisoning. We mention these considerations to emphasize the point that a very large amount of work over prolonged periods will be necessary before any certain and final conclusions can be reached in this difficult problem.

### ANTI-STREPTOCOCCAL ACTION OF CERTAIN ARSENICAL PREPARATIONS.

SOME interesting and possibly important conclusions with regard to the application of chemotherapy to streptococcal infections are to be found in a special report<sup>1</sup> which is published this week by the Medical Research Council. This contains an account of a study by Dr. Leonard Colebrook of the effect of certain organic arsenical compounds on streptococci *in vitro* and in the human body. During the war Captain S. R. Douglas, R.A.M.C., and Dr. Colebrook, both working in connexion with the Council, commenced an investigation into the use of drugs of the salvarsan and neosalvarsan type in the treatment of wound septicaemia. More recently Dr. Colebrook has turned his attention to puerperal infections, and has attempted to provide data for planning a chemotherapeutic attack upon such conditions. He has studied the degree and duration of bactericidal power conferred upon the blood by the administration of different doses of various arsenical compounds, and has also considered the complicating factor of concurrent leucocytic poisoning. It is mentioned that careful clinical trials on similar lines are also proceeding in London and Manchester.

#### Nature of the Experimental Work.

The starting point of the present inquiry was the belief that the anti-syphilitic arsenicals, when administered to man, might exert a directly destructive action upon pathogenic bacteria in the body as well as upon spirochaetes and protozoa. The first demonstration of the conferring of bactericidal power on the blood serum by the administration of a drug was made by Sir Almroth Wright in 1912 in connexion with the guinine derivative ethyl hydro-euprein, or "optochin," which Morgenroth and Levy in 1911 had shown to be capable of saving mice experimentally infected with pneumococci. Douglas and Colebrook in 1916 demonstrated that similar results followed the use of neosalvarsan in the case of staphylococci. Many other chemical agents have since been tried, but on entering the blood stream they appear to become "fixed" by the serum proteins, the blood cells, or the tissues. Moreover, Fleming's work in 1924 made it clear that so much damage might be done to the normal protective elements in the blood, particularly to the leucocytes, that far more harm than good might result from the use of such drugs in treatment. The present investigation, therefore, was directed also to ascertain whether the injection of medicinal doses of certain drugs would injure the normal protective mechanism of the body. The arsenical compound to be tested was accordingly added in increasing quantity to human blood *in vitro*, and its effect was observed upon the phagocytic capacity of the blood, the appearance of the leucocytes, and the bactericidal potency. It was found that the addition of arsenicals to normal blood *in vitro* had little effect upon its opsonic power other than to increase it slightly sometimes. All the compounds incubated with normal blood in amounts exceeding one part in 40,000 for

<sup>1</sup> *A Study of Some Organic Arsenical Compounds with a View to their Use in Certain Streptococcal Infections*. By Leonard Colebrook, M.B., B.S. Medical Research Council, Special Report Series, No. 119. London: H.M. Stationery Office. 1928. 1s. 3d. net.

twenty-four hours exerted a slowly destructive action, chiefly on the polymorphonuclear and large mononuclear leucocytes. The next step was to determine whether the leucocytes in the body were similarly affected, and it was shown that whereas after a large dose of novarsenobenzene there was a falling off in the activity of the leucocytes in three cases out of four, particularly when the patients were suffering from severe infections, the administration of kharsulphan and metarsenobillon did not appreciably reduce the leucocytic efficiency, even when given in doses which maintained bactericidal potency in the serum for two to four days. It became likely, moreover, that by suitably adjusting the dose of the arsenical preparation in the blood it would be possible to secure bactericidal potency without doing any appreciable harm to the leucocytes. To establish this point experiments were performed upon the blood *in vitro* and also in the living body.

#### Summary of Experimental Results.

A small group of trivalent arsenicals comprising salvarsan and two of its derivatives—namely, novarsenobenzene and the dimethylene bisulphite (sulfarsenol, metarsenobillon, and kharsulphan)—were found to exhibit certain properties distinguishing them sharply from almost every other known compound which it has been proposed to use for the chemotherapy of bacterial infections; no pentavalent arsenical showed these properties. When injected into the living body this small group conferred upon the blood the peculiar bactericidal powers characteristic of their simple solutions, which powers were retained by the blood for a considerable time. It is suggested that, owing to the slowness with which these drugs are excreted and enter into combination with the blood or tissue cells, a considerable portion of the injected dose is retained for a time in solution in the blood plasma. This bactericidal effect is most marked in the case of the haemolytic streptococci and the pneumococci; streptococci of the *viridans* group and staphylococci are less affected, while there is hardly any action on the enterococci and certain diphtheroid and coliform bacilli. It was found that 1 c.cm. of the serum from a patient who had received an injection of one of these arsenical compounds would sometimes kill as many as one to two million haemolytic streptococci, but somewhat lower figures were more usual. The bactericidal power thus acquired by the serum reaches its highest point immediately after an intravenous injection of novarsenobenzol; it then diminishes, somewhat rapidly at first, and then more slowly, during the following twenty-four to forty-eight hours. By the intramuscular or subcutaneous injection of metarsenobillon, kharsulphan, or sulfarsenol, repeated at suitable intervals, it has been maintained in several patients for three or four days, and in one case, using metarsenobillon, for four weeks. The arsenic compounds tested were found to have the following order as regards toxicity for human leucocytes. The least toxic were metarsenobillon, kharsulphan, and sulfarsenol, approximately equal; next came stabilarsan, salvarsan, and neosalvarsan, while the most toxic of all was silver salvarsan. The leucocytes of patients suffering from very severe streptococcal infections were found to have an increased sensitivity to this toxic action. It was shown experimentally that the dosage could be adjusted so as to secure the minimal effect on the leucocytes with a maximal bactericidal potency of the blood. In solutions of low concentration or in the serum of patients it was found that the bactericidal effect was very slow in developing; implanted streptococci often multiplied at first, but were killed after a period of six to twenty-four hours.

#### Lines of Future Investigation.

Dr. Colebrook concludes his report by mentioning a number of questions arising out of his results and requiring further research. There is, first, the elucidation of the source of the bactericidal power; is it due to the simple solution in serum of the drug, or to the presence of some "alteration product" formed in the body, or to the elaboration of some antibody under the stimulus of the arsenical? At present the evidence indicates that the first of these is concerned. The second question is whether the bactericidal power is related to one specific feature of the chemical structure of the arsenical preparation; if this

could be established as a fact the way would lie open to the preparation of still more effective therapeutic agents. The nature of the difference in the action between these drugs and other disinfectants is striking, and invite research, as also the question whether the streptococci can become resistant to them. Another interesting and practical point is the possibility that both spirochaetes and bacteria which are not killed by dilutions of arsenicals in a short time, such as one or two hours—the usual experimental period—may succumb to weaker dilutions if exposed to them for some days, as has been shown to be possible now with certain of these in the human body. A series of doses is suggested for the clinical use of the three selected arsenicals by intramuscular and subcutaneous injections and the importance of improving the circulation through the infected areas is emphasized. This report will undoubtedly provoke discussion and stimulate research in what may prove to be a very fruitful field.

#### CONFERENCE ON MATERNAL MORTALITY.

A VERY largely attended meeting to discuss maternal mortality was held at the Westminster Central Hall on February 28th. The gathering consisted almost entirely of women, who represented county nursing associations, infant welfare centres, and maternity and child welfare committees. The chair was taken by the Hon. Mrs. ALFRED LYTTELTON, D.B.E., who was supported by Sir George Newman, Dame Janet Campbell, Lady Barrett, and others whose names appear in the list of speakers. A message from the Queen was read stating that Her Majesty viewed with grave concern the continued high rate of maternal mortality, and felt that a very real endeavour should be made to remove this reproach from the national life. "The Queen trusts this may be achieved through the education of mothers themselves in the need for ante-natal care, through inquiry into the immediate causes of mortality in childbirth, and through a wider provision of first-rate medical and midwifery services."

At the conclusion of the meeting the following comprehensive resolution was carried unanimously:

That steps should be taken to obtain a medical inquiry into every maternal death due to childbirth;

That the attention of the authorities responsible for the education of medical students should be drawn to the need for further training and experience in midwifery as a preliminary to general practice in medicine;

That an official committee should be set up to advise upon the whole question of the training and employment of midwives;

That action should be taken in every area to induce all local authorities to make their maternity services adequate;

That the provisions of the National Health Insurance Acts should be readjusted and extended so that medical and midwifery services should be available for mothers both for ante-natal care and during and after confinement.

It was understood that the resolution would be sent to the Ministry of Health.

Dr. J. S. FAIRBAIN said that maternal mortality was lowest in those countries, like Holland, which had a well-trained service of midwives. In particular he emphasized the importance of post-certificate training, mentioning also that the Universities of Durham and Leeds now assumed a lecture course for midwives as part of their university duties. But in addition to the training of midwives it was necessary to make the profession economically and otherwise attractive enough for women to practise it.

Mr. ARTHUR GREENWOOD, M.P., formerly Parliamentary Secretary to the Ministry of Health, said that there were three lines of possible advance: the development of national health insurance, the development of the work of local authorities as regards maternity and child welfare, and the improvement of the social environment. If only the existing powers of local authorities with regard to ante-natal and post-natal care were fully carried out the stubborn total of 3,000 maternal deaths a year would begin to decline.

After Miss STREEK had spoken from the point of view of rural nursing, and Mrs. HARRISON BELL, a signatory of the Minority Report of the Royal Commission on National Health Insurance, had urged additional insurance benefits in the shape of midwifery, medical examinations before and after confinement, and medical attendance at the confinement if necessary,

the meeting was thrown open to general discussion. Dr. S. G. Moore said that there was a town in England where the women who were confined might be divided into two groups. In one group there were three times as many maternal deaths as in the other. In the group with the low death rate every woman was visited during pregnancy by a woman doctor, who saw to it that she was normal, or, if not normal, sent a report to her family doctor, whereby the case was followed up.

Lady SELBORNE said that the United States had a higher maternal mortality than Great Britain, and there it was doctors who were employed, not midwives. She thought that conditions were better now, but she recalled a time when doctors in attendance on lying-in women took extraordinarily few precautions. Another speaker, who said that she was a town councillor, declared that the crux of the problem was the training of the medical student. This lady urged that doctors should be subjected to the same discipline as midwives, and suffer the equivalent penalty if they neglected to observe any proper care. Miss E. M. DOUBLEDAY thought that the appointment of doctor at the ante-natal centre should be given to one who was specially qualified for the work. Many of these appointments went to persons who had no special experience in obstetrics.

Dr. ETHEL BENTHAM urged that the necessary research into this whole subject should include an economic as well as a medical inquiry. Another speaker regretted the absence from the resolution of any reference to permanent injury and invalidism resulting from childbirth. The conclusion of one health visitor who spoke was that the death rate was practically level in all classes of society. One speaker, again a woman, ventured to plead for good scientific teaching on birth control to be given at the ante-natal centres.

A strong determination was evident throughout the debate that the total of maternal mortality must by all means be reduced; but the remarks of many who spoke from the side of the social and municipal services seemed to betray a feeling that, in the exact words of Lady Selborne, "there is a danger in the doctor"!

## Canada.

[FROM OUR SPECIAL CORRESPONDENT.]

### British Columbia.

A PLAN has been evolved in British Columbia for the collection of convalescent serum for the treatment of anterior poliomyelitis. This has been made possible by the action of the Provincial Board of Health Laboratories of British Columbia, who have announced that they will pay 5 dollars for useful quantities of blood (80 to 100 c.c.m.), and in proportion for larger amounts. This is the rate at which ordinary donors of blood for transfusion are paid. The laboratories will be responsible for collecting the blood, testing its Wassermann reaction and preserving it on ice, subject to call in suitable cases. It is intended to use the serum especially in the treatment of early or advancing cases, and if supplies permit, for prophylaxis also. This action is a commendable example of foresight in dealing with this disease, which was existent in the West to a disconcerting extent within recent months, although not assuming the nature of an epidemic.

### The Hospital Campaign in Montreal.

An interesting issue has developed out of the last campaign for financial support of the hospitals in Montreal. One of the first and largest subscriptions to the fund was from the Bank of Montreal, to the extent of 200,000 dollars, and other banks and corporations were similarly generous. The contribution of the Bank of Montreal is now being opposed by some of its shareholders in the city of Quebec, who seek to set aside this gift on the ground that such donations are in excess of the powers of the board of directors under the Bank Act. The action is generally regarded as a test case to decide the right of directors of corporations to make donations to public institutions. The defence is made that the money is being devoted to the work of four hospitals in Montreal, which are of service to all the inhabitants of the province, irrespective of race or religion, and that many of their patients are unable

to pay for the cost of their treatment. It is pointed out also that these hospitals render a much more widespread service to the community at large by their training of nurses, besides providing clinical facilities for the medical faculties of universities. For the hospitals to carry out these functions properly involves a continual and heavy outlay, and if such burdens were not borne in part by voluntary subscription the cost would have to be met by taxation, in which corporations would have to take their part. The success of the campaign, it was shown, depended on the advance pledges of the banks and corporations. Many of the larger subscriptions were secured on the express understanding that at least 3,000,000 dollars would be pledged before the opening of the campaign. It has been the custom for many years to raise funds for the hospitals by such campaigns, and it has always been recognized that contributions by banks and other organizations are a necessary incident in the business conducted by them in the community from which they derive their revenues. This particular subscription from the Bank of Montreal was not at all disproportionate to its position and the value of its business in the community, quite apart from the fact that the business of the bank, as of other corporations, is dependent largely on the growth and welfare of the city and upon the provision made for the care of the sick, including the employees of the customers and depositors, as well as of the banks themselves. One direct interest of the Bank of Montreal in the campaign arose from the fact that out of the money collected the bank has already received substantial repayments on account of advances previously made in the form of overdrafts to the hospitals.

### Scholarships for Tuberculosis Workers.

As evidence of their continued interest in public health the Sun Life Assurance Company have taken steps to provide travelling scholarships for salaried tuberculosis workers in Canada. It is recognized by the company that the grant which they have so generously given towards extra-mural teaching of medicine in Canada (which is now being renewed for its third successive year) does not reach those engaged in the specialization of tuberculosis. They therefore have offered thirty travelling scholarships, to be given to those named by the Canadian Tuberculosis Association. Each candidate will receive 500 dollars from the company, provided that a similar amount is added by the executive of the association, at the same time granting leave of absence with continuance of salary. The recipients will travel in England, France, and Italy, visiting research laboratories and institutions for the tuberculous. Perhaps the activity which it is most desired that they should study is the sheltered employment schemes in England for the families of the tuberculous, especially the Papworth colony.

### The Law Regarding Narcotics.

The stringency of the law in Canada regarding the giving of narcotics is illustrated by a recent case in Ontario. It happened that a young doctor just beginning in practice gave some ground for suspicion that he was violating the law, and a trap was set for him by the detective department. As a result of this he was found to give morphine and cocaine in considerable quantities, to be carried away by the patient. He was accordingly convicted before a police magistrate, who, taking the circumstances into account, did no more than fine him 200 dollars. This sentence was carried to the Court of Appeal, which not only upheld the judgement, but found that the sentence had not been in accord with the requirements of the law, which imperatively required imprisonment. The upshot was a sentence of three months in prison (the shortest term allowed). The *Canadian Medical Association Journal* has taken this opportunity to remind the medical profession generally of the law on the matter.

### Professor J. B. Collip.

The Medical Faculty of McGill University announce the appointment to the chair of biochemistry at McGill of Professor J. B. Collip, at present on the staff of the University of Alberta. Professor Collip's brilliant research work on the parathyroid glands is well known, and the

Montreal University have reason to be proud that he has been added to their staff. He succeeds Professor A. B. Macallum, who has resigned after a more than usually long and brilliant career in teaching and research.

## Union of South Africa.

[FROM OUR CORRESPONDENT IN PRETORIA.]

### Health of Pretoria.

PRETORIA, the administrative capital of the Union of South Africa, lies in the high veld, and its altitude of 5,000 feet above sea-level preserves it from a tropical climate. North of Pretoria the land slopes away rapidly to the low veld, and sub-tropical conditions are soon encountered. Nevertheless, sultry conditions are met with in the capital, and in very wet summers malaria is liable to occur in the district. The year ended last June was particularly dry, there having been only twenty inches of rain—approximately half of the previous year's rainfall. Only twelve cases of malaria were notified in the municipality during the year; eight of the patients had either come to Pretoria from elsewhere or had been infected outside the area. Of the four locally infected persons three lived near the railway lines to Delagoa Bay and Pietersburg, regions in which malaria is prevalent; the train transport of infected anophelines is not an uncommon event. The rainy season, as elsewhere in the Transvaal, occurs chiefly in the latter half of the summer, and the present year has been ushered in by very heavy rains. Conditions favourable for mosquito-breeding are therefore being produced in the district, and the health authorities are intensifying the preventive measures. The oppressive summer conditions are not entirely due to latitude. The town lies in a valley between parallel ranges of quartzite hills running east and west. Air movement is therefore much restricted, and the cooling power of the atmosphere is considerably less than that of Johannesburg on the south, which, in addition to being freely windswept, is located a thousand feet higher on the high veld. Privileged houses are rapidly creeping up the slope of the southern range of hills. Here are cooler conditions, and the houses have the northern aspect which is so much sought after in the southern hemisphere.

In his annual report for the year ended June, 1927, the medical officer of health draws attention to the very satisfactory European vital statistics. The European population, exclusive of the inmates of the central prison, mental hospital, and leper institution, is 42,000, and there are 23,000 coloured persons—Africans, Eur-Africans, and Asiatics. The European death rate was 6.99 per 1,000, as compared with 7.7 in the previous year. The death rate for the coloured races was 16.0 per 1,000. The European infantile mortality rate of 48.48 per 1,000 births is the lowest on record for Pretoria; last year's figure, which was considered to be very low, was 2.5 higher. The non-European infantile mortality rate continues, however, to be high—315 per 1,000 registered births. Excluding imported cases the infectious diseases notified among Europeans were: typhoid 67, scarlet fever 25, diphtheria 20, measles 209, whooping-cough 100, other infections 33; among non-Europeans: typhoid 26, diphtheria 2, measles 17, whooping-cough 8, tuberculosis 13, other infections 8. The high typhoid incidence among Europeans is partly to be attributed to the zeal of the local health authorities in searching for hidden cases. This is supported by the fact that only two of the Europeans died, whereas of the twenty-six natives eight died. These figures suggest that most of the European cases, even when comparatively mild, are notified, whereas the bulk of the milder native cases escape notification. In diagnosis blood tests are extensively used, and many of the clinically doubtful cases were diagnosed by a positive complement fixation test. Nevertheless, the number of cases is high for modern conditions, and protective vaccination was extensively employed by Besredka's oral method. The vaccine was administered, in all, to 1,497 persons—545 Europeans and 952 non-Europeans. The individuals so immunized included 830 persons living in houses from which cases

had been notified, 296 persons employed in dairies, and 171 natives newly engaged by the town council and housed in the municipal location. This method of administering dead cultures of typhoid bacilli by mouth was found to be quite effective, and for preventing the contamination of milk by ambulant native patients or intestinal carriers the method is considered by the medical officer of health to afford much greater security than does periodical blood testing of native employees. The chief cause of the local primary outbreaks appears to have been contaminated milk, which was proved to be responsible for at least twenty-one cases. The continuance of the conservancy system in certain parts of the town is also blamed, and is undoubtedly a very important cause of spread of intestinal diseases. With its rapidly growing population Pretoria is having some difficulty with its water supply, and schemes are under consideration for its increase. In dry spells inhabitants are not permitted to use the municipal supply for flower gardens. Slight contamination still appears to occur at all the sources; of 161 samples taken during the year at the various intakes and reservoirs, 89 showed *B. coli* in 20 c.cm. or less. The degree of contamination is hardly dangerous, but it is evident that some of the springs are not sufficiently protected.

### Native Infantile Mortality.

The lay press is giving prominence to the high native infantile mortality figures appearing in the recently published health reports of the larger Transvaal towns. In Pretoria the figure for all coloured races last year was 315 per 1,000 registered births. The natives (Bantus or Kaffirs) suffered most heavily, their rate being 388.5 per 1,000, though this figure is an improvement on that of the previous year, which was 483 per 1,000. In Benoni the rate is quoted as 847 per 1,000, the number of deaths in native infants under 1 year in January, 1927, being equal to the number of births during the month. On the West Rand conditions, though bad, are better than on the eastern end of the Reef; in Krugersdorp last year the native infantile mortality rate was 320.14 per 1,000 births, but these figures undoubtedly exaggerate the state of affairs. Notification of native deaths is practically complete, but that of births is very defective. The reason for this is probably that the native parent is apprehensive of additional taxation following on admission of increased population. In these circumstances a death rate stated in terms of the number of births is clearly misleading. Still, the number of native infant deaths in the larger towns has for many years been notoriously high. This is to be attributed very largely to the insanitary conditions under which these people reside in the towns. In the kraals where they live simple, if exceedingly primitive, lives the mortality would appear to be lower, although accurate figures are unobtainable. Many of the children in the towns are the offspring of prostitutes; they are often neglected, and in some cases deliberately allowed to die. With a large native male population living for twelve-month periods in compounds along the Reef, prostitution is almost unavoidable. Conditions are, however, being greatly improved by the Government's active policy of removing from urban and industrial areas all native women not officially married either by European or Bantu custom, and by limiting the numbers of married natives in the towns strictly to those that are required for labour purposes. The Natives (Urban Areas) Act allows individuals from the native territories to remain in towns only long enough to seek employment. If at the end of that time employment has not been obtained the native returns to his kraal. By these means it is hoped to prevent the further detribalization of the Bantu races. Experience has abundantly proved the evil results of close association in slum areas of detribalized natives and Europeans. In the industrial compounds the male native is well looked after, and his health in general is very good; it is when he finds his way into the poorer quarters of the towns and has no fixed employment that the worst evil results to health and morals occur.

### Health Legislation.

In the annual report of the Department of Public Health Dr. J. A. Mitchell, Chief Health Officer for the Union, reviews the legislation affecting public health passed during

the last parliamentary session. Certain clauses only of the Public Health Act Amendment Bill were passed as Act No. 36 of 1927. That dealing with the alluvial diamond diggings makes the Mining Commissioner, acting under the authority and instructions of the Minister of Public Health, the local authority. Some direct sanitary supervision of the diggings had become an urgent necessity. Supporting for often quite long periods a large population who are content to exist in the most deplorable huts, sanitation is considered to be of secondary importance, and the most noisome conditions are tolerated. Typhoid soon makes its appearance, and emergency hospitals have to be constructed. Another clause makes provision for periodical visits by medical officers to places lacking medical aid, the cost being met out of moneys specially voted by Parliament for the purpose. The unfortunate position of the small farmer or settler in remote localities, often forty or more miles from the nearest doctor, and not infrequently in a malarial area, had attracted public attention. If his cow or horse becomes ill a Government veterinary officer is available on payment of the bare transport costs of the officer; but if the farmer or a member of his family is affected the Government has in the past given no assistance, and he has had to summon a medical practitioner at ordinary rates—which the necessary time and transport rates render ruinous or prohibitive if repeated visits are required. To remedy such conditions the Chief Health Officer advises the co-ordination and unification of local and central administrations with control of preventive and curative activities, coupled with the cautious and gradual building up of a State-aided medical service, both preventive and curative, for all members of the public who wish to avail themselves of it, beginning with the inhabitants of remote and perhaps malarial rural areas, and with school children in both urban and rural areas throughout the Union. The clause in the present Act makes a beginning in this direction. It reads:

"Wherever the Minister is satisfied that, owing to lack of medical aid, prevalence of malaria, or other disease, or other special circumstances in any area, assistance from public funds in providing facilities for the medical treatment of the inhabitants of such area is justified, he may, out of moneys specially voted by Parliament for the purpose, provide for periodical visits to a centre in such area by a district surgeon or other medical officer."

Such visits or tours will not only bring medical aid within reasonable reach of the inhabitants, but will also encourage prevention of insanitary or unhealthy conditions, local, domestic, or personal. Indigent patients, so certified by a magistrate, will be treated free; all others will be treated at the same rates as are charged by the district surgeon at his headquarters, and, where special travelling is involved, only the extra mileage will be charged, the Government paying the cost of travelling to and from the out-station. This system, while ensuring fair remuneration to the doctor, does not tend to pauperize the people. It is hoped that it will prove very useful and advantageous, not only to the inhabitants of the areas concerned, but, by promoting agricultural and general development, also to the Union as a whole.

## Scotland.

### Edinburgh University New Professors.

At a meeting of the Curators of Patronage of the University of Edinburgh, held on February 23rd, Dr. W. T. Ritchie was elected professor of medicine in succession to Professor G. Lovell Gulland. Dr. Ritchie was educated at the Edinburgh Academy and graduated M.B., C.M. at Edinburgh University in 1896. After graduation he held the post of resident physician to the late Sir James Affleck, and subsequently spent a period of post-graduate study at Vienna. After holding various positions as clinical tutor and assistant pathologist in the Royal Infirmary, Edinburgh, he became assistant physician to this institution. During the late war he served with the R.A.M.C. in Egypt, and for his services in this connexion was awarded the O.B.E. He is the author, in collaboration with the

late Dr. Graham Brown, of *Medical Diagnosis*, a manual of clinical methods, and, with Dr. John Cowan of Glasgow, of a textbook on *Diseases of the Heart*. He has also published numerous papers dealing with heart-block, the action of the vagus nerve on the heart, the action of the heart in health and disease, etc. For some years after the war he acted as a lecturer on the practice of medicine in the School of Medicine of the Royal Colleges at Edinburgh, and he at present holds the position of physician to the Royal Infirmary, Edinburgh, and consulting physician to the Deaconess Hospital, Edinburgh.

At the same meeting of the Curators Professor James Kendall, professor of chemistry in New York University, was elected professor of chemistry at Edinburgh University in succession to Sir James Walker. Professor Kendall is an Edinburgh graduate, having taken the degrees of M.A. and D.Sc. at Edinburgh. After graduating he engaged in research under Professor Arrhenius at Stockholm, and became instructor in chemistry in Columbia University at New York in 1913. In 1922 he was appointed professor of chemistry at this University, and edited and revised the textbooks on chemistry of his predecessor, Professor Smith. Professor Kendall has published many original communications dealing with inorganic and physical chemistry, and he was elected a Fellow of the Royal Society in 1927.

### Jubilee of the Caledonian Medical Society.

The jubilee meeting of the Caledonian Medical Society was held at Edinburgh on February 23rd and 24th. It may be recalled that this society traces its beginning to February 23rd, 1878, when three Highland undergraduates attending Edinburgh University decided to found a society with the object of promoting the professional knowledge of its members by the consideration and discussion of medical and surgical subjects. They were afterwards joined by four other enthusiastic Celts, and the seven members held weekly meetings at their various rooms for the discussion of papers contributed by each member in rotation. Most of the original members qualified in 1878, and the society remained in abeyance until 1881, when five of the seven original members met in Manchester to reconstitute it. The membership was then enlarged to fifteen, and a manuscript journal was started which was circulated among the members. During the next few years the number of members increased to thirty, and annual meetings were held in various parts of England and Scotland. In 1891 it was resolved to have the journal printed, and it has now become a regular quarterly publication. To-day the society has a membership of 500, including Scotsmen scattered over Britain and the dependencies beyond the seas.

### Festival Dinner.

The jubilee proceedings began, on February 23rd, with a dinner in the hall of the Royal College of Physicians, Edinburgh, at which about 120 members and guests were present. The chair was taken by Dr. S. Rutherford MacPhail, and Dr. W. A. Maenaughton acted as emcee. These members, who were two of the original three founders, are joint presidents of the society for this year; the third founder, Dr. Donald MacLennan, died twenty-three years ago. The toast of "Caledonia" was proposed by Lord Alness, Lord Justice Clerk, and that of "The Universities and Medical Corporations of Scotland" by Dr. David Rorie. The latter toast was acknowledged by Professor H. J. C. Grierson of Edinburgh University, who referred to the tie which had always subsisted between medicine and literature, by Dr. R. A. Fleming, president of the Royal College of Physicians, and by Mr. Alexander Miles, president of the Royal College of Surgeons.

The Rev. Dr. Norman Maclean, Moderator of the General Assembly of the Church of Scotland, proposed the toast of "The Caledonian Medical Society," and in doing so said that the Church was really the mother of the medical profession, which had sprung out of the bosom of the Church in the Middle Ages, when the churchman and the doctor were one person. To-day, he added, the medical profession and the Church were two hands of the one institution, and the glory of the medical profession lay in the general practitioner. The chairman, replying to this toast, recalled the history of the society, and said that its 500 members

to-day had more ambition than those of most other medical societies because they had a special patriotic side to preserve—the medical aspect of Celtic tradition, Celtic literature, and Celtic folklore, which were in danger of passing into oblivion. The toast of “The Guests” was proposed by Dr. C. E. Douglas and acknowledged by the Rev. Dr. J. Harry Miller, C.B.E., Moderator-Elect of the General Assembly of the United Free Church of Scotland.

#### Annual Meeting.

The annual meeting of the society was held on February 24th in the hall of the Royal College of Surgeons, Edinburgh, when Dr. W. A. Macnaughton gave a presidential address in which he referred to some of the changes which had taken place in medical life and medical knowledge and practice since 1878, when all the medical classes were taught within the walls of the old University, for the new medical school had not yet arisen. Speaking of the cost of living in 1878, he said that while 35s. a week was regarded as the average expenditure of a student for board and lodging, he himself had shared a room with a fellow student who became one of the best practitioners in the North, and their landlady's weekly bill seldom exceeded one-third of this figure. Modest as these figures were compared with present-day charges, he had been assured by an Aberdeen graduate of the same period that his weekly bill, eked out by regular parcels from home, seldom exceeded 6s. The medical classes at that time, in the seventies included a larger proportion of students than they did now. Referring to the services in the Highlands and Islands, he said that a great change had taken place since 1878 with respect to medical attendance and skilled nursing within the Highland area. The central feature of the scheme, which had been introduced in 1912, was that no patient, however far he might be from the doctor's residence, should pay more than 5s. for a first visit and 3s. 6d. for a subsequent visit in the same illness, the mileage for such visits being payable out of a central fund subsidized by the Government. This was a great concession to the struggling crofter who lived in some Highland glen twenty miles from the nearest doctor. To the doctor the advantages of the scheme were that his payment was assured, although he had probably far more travelling and less leisure now than in the past. Highly qualified surgeon-consultants had been established in such places as Stornoway and Lerwick, where local hospital facilities were available; and before long a system of other specialized services would be introduced. The last fifty years had also witnessed the establishment, by local endeavour, of a large number of cottage hospitals in various parts of the Highlands, and no doubt the usefulness of these could be still further extended if they were linked up with a general hospital such as that at Inverness. In the near future, too, every parish, both on the mainland and in the Hebrides, would enjoy the advantages of the services of a duly trained nurse.

#### Reception by the University.

In the afternoon a reception was given by the University of Edinburgh to the society. Principal Sir Alfred Ewing received the guests in the Upper Library Hall in the Old College, and, in an address of welcome, referred to the jubilee of the society as a remarkable attribute to the efficiency with which it had fulfilled its intended objects. A number of medical manuscripts and early printed books, referring chiefly to Scottish medicine, were on exhibition in the hall, and an address dealing with these was delivered by Dr. John D. Comrie. Dr. Comrie's survey included Michael Scot's book on physiognomy, of which no fewer than eighteen editions had appeared between the early printed copy of 1477 and the year 1660. From 1400 onwards there had been a copious Gaelic medical literature in Scotland belonging to the medical attendants of the Highland chieftains, usually members of the families of Macbeth or Macdonnachie. These showed that the Highland physicians were well-educated men, with a knowledge of Latin, who had travelled abroad. Reference was also made to a fifteenth century Lowland Scottish practitioner, William Schevez, who amassed at St. Andrews a notable collection of books, and who was for many years physician to James III. Several Latin translations of

Galen and other ancient writers were also shown, as well as more recent manuscripts, including a small book bearing the title *Ane Gude Boke of Medicines Called the Treasure of Poore Men*, 1595, which was typical of the medical treatises upon which the Scottish doctors relied after the influence of the Church, with its monastic libraries, had passed away. A copy of the *Discourse on the Whole Art of Chyrurgerie* by Peter Lowe, who, in 1597, was the first Scottish writer on surgery, was also exhibited.

#### Glasgow Royal Infirmary.

The 133rd annual meeting of the Glasgow Royal Infirmary was held on February 13th in the Merchants' House, Glasgow. Lord Provost Mason presided, and referred to the necessity which at present existed of obtaining added subscriptions to meet the increased activity of the institution. Mr. James Macfarlane, LL.D., chairman of the managers, referred to the proposed auxiliary hospital and nursing home at Canniesburn, and said that the managers were waiting till they had collected a sum of between £50,000 and £60,000 before proceeding with the building. Up to the present £45,000 had been received or promised spontaneously, and the managers now felt that the new scheme might be begun. The managers felt some anxiety about meeting the cost of maintenance at the infirmary, as the report showed this had been steadily increasing, and when the new extension was set up the cost would be still further augmented. He was confident, however, that the public of Glasgow would provide the necessary funds. The report shows that in the year 1927 the number of persons who received treatment at the infirmary was 82,852, a figure which represented 8,733 persons in excess of those who received treatment during the previous year. On the financial side there was a shortage over the year's working of £12,896. The ordinary expenditure amounted to £119,464, while the average cost of each patient under treatment was £7 4s. 7½d., as compared with £7 16s. 9½d. for the previous year.

## England and Wales.

#### Mental Deficiency Act, 1927.

THE Board of Control has issued a pamphlet (Circular 702) drawing the attention of local authorities to the provisions of the Mental Deficiency Act, 1927. This Act removes certain defects in the principal Act (the Mental Deficiency Act of 1913), and also enlarges the powers, and to some extent the duties, of the local authorities. Under the principal Act the condition of mental defectiveness was defined as one which must have existed “from birth or from an early age.” Under the new Act mental defectiveness is defined as “a condition of arrested or incomplete development of mind existing before the age of 18 years, whether arising from inherent causes or induced by disease or injury.” The altered definition allows, therefore, cases of mental defect arising from encephalitis lethargica to be dealt with under the Act. Indeed, it was the large number of such cases throughout the country that led to the repeal of the definition of mental defectiveness as stated in the principal Act. The need for providing suitable accommodation for such post-encephalitic cases was urgent. There is now no legal impediment to their being certified as mentally defective, and so trained and cared for. The criterion of certifiability, except in the case of feeble-minded children, is whether the individual is so mentally defective that he requires care, supervision, and control.

#### Cancer Research in Birmingham.

Following the favourable reports from Liverpool on the treatment of malignant disease with lead by Professor Blair Bell and his fellow workers, a subcommittee was appointed to have medical control over cancer research in the Birmingham General Hospital, and it was decided to investigate the use of lead in such conditions. After various initial difficulties had been overcome, in-patient accommodation was obtained, since it was found that the treatment could not safely be given to out-patients. The report of the committee on the work accomplished in 1927

has now been published in the February issue of the *Birmingham Medical Review*. The number of cases of malignant disease treated with lead was thirty-four; nineteen of the patients were women and fifteen men. The preparations used were colloidal lead in twenty-three cases, lead glycine in eight, and both preparations in two cases. The remaining patient received an injection of colloidal lead prepared in the hospital laboratory with gum arabic. The questions of toxicity and the too rapid decomposition of the lead preparation were carefully studied, and a colloidal lead phosphate was found to be most suitable, though lead glycine proved to be markedly less toxic. The committee concludes that, since ten of the thirty-four patients derived benefit, lead treatment has a distinct therapeutic value, and deserves further investigation. In view of the very small quantities of lead found in the tumours examined the committee doubts whether Blair Bell's original hypothesis of a specific affinity of cancer tissue for lead can be upheld. It is thought more likely that the action of this metal is indirect, and that two explanations are possible: (1) that lead injections stimulate the production of some active body in the serum, liver, or elsewhere; (2) that colloidal lead or lead salts, by their conversion to phosphate after injection, must render some of the phosphate of the blood unavailable in its usual form—nuclein synthesis, a necessary accompaniment of growth, might thus be effected. It is added that there is reason to believe that the main therapeutic value of lead lies in its ability to restrain metastasis or to destroy small and recent growth deposits. With the exception of one case of sarcoma in bone, no benefit was obtained by any patient who had a large malignant mass. It is thought that the most profitable results will be obtained by treating patients who have undergone palliative incomplete operations, either by surgery or radiation.

#### Supervisory Centres for "Rheumatic" Children.

The Education Committee of the London County Council has had under consideration a resolution from the Invalid Children's Aid Association asking that the school medical service may keep in closer touch with elementary school children who are "rheumatic" and marked for observation. The committee records what has already been done under arrangements made recently by the Metropolitan Asylums Board whereby certain beds are set apart at Queen Mary's Hospital, Carshalton, and elsewhere for children suffering from rheumatism, heart disease, and chorea. Up to December 31st 170 children had been admitted under this scheme, but 535 nominations had been received, and fresh plans are being pressed forward at Queen Mary's which will give 350 places for rheumatic children at that hospital. Children who have hitherto failed to obtain admission owing to lack of accommodation are being assiduously followed up by the school medical service and by the association just named. Co-operation with the medical officers of the metropolitan boroughs has also been established. In Kensington and Paddington rheumatism in children has been made a notifiable disease, and in cases where the home of a rheumatic child, dealt with under the scheme, seems to have a bearing on the etiology of the disease, the medical officer is informed, with a view to improving the home conditions before the child returns from the residential hospital. The committee is of opinion that in London some progress has been made along all the various lines of action for local education authorities summarized by Sir George Newman in *The Health of the School Child*. The school doctors are paying special attention to rheumatism, a register of cases has been established, school supervision is being carried out, and residential accommodation for acute and subacute cases is being organized. What is now chiefly required is the development of rheumatism supervisory centres to which parents might bring suspected children or children requiring observation. At such centres advice would be given upon management, and the first symptoms would be detected, suggesting the necessity for special measures. Three rheumatism supervisory centres have already been established in West London—namely, in Paddington, Marylebone, and Kensington. The committee is of opinion that no attempt should be made to organize such centres as

*ad hoc* institutions, but that they should be formed in natural relation with the other remedial activities at hospitals and treatment centres already provided under the council's scheme. It is also thought that it would be advantageous to have some experience on a limited scale before a complete scheme is devised, and endeavours are therefore to be made during the coming year to organize five such centres on experimental lines—two in North-east and East London, to be formed at hospitals (for which purpose the Queen's and the London Hospitals appear to be the most suitable), and three in South London in association with treatment centres. The two hospitals to be invited to co-operate will receive a grant of £100 a year, and the authorities of the centres will be given increased provision for medical, nursing, and organizing assistance. The general administration of the arrangements for rheumatic children will be in the hands of one of the assistant medical officers of the public health department.

#### District Nursing in London.

At the annual meeting of the Central Council for District Nursing in London on February 23rd, under the presidency of Sir William J. Collins, the principal matter brought up on the report of the executive committee was the recent change of policy on the part of the Metropolitan Asylums Board with regard to scarlet fever and measles. Until lately the Board's hospitals were available for all scarlet fever patients requiring admission, but only a limited number of measles patients were received when accommodation was available. In view of the decline in the severity of scarlet fever, however, and of the fact that the death rate from measles in London is now six times as great as that from scarlet fever, greater facilities have been afforded by the Board for the treatment of measles, and the beds for scarlet fever patients have been restricted. After a conference with medical officers of health of the metropolitan boroughs and others, the executive of the Central Council has come to the conclusion that the home nursing of scarlet fever can be undertaken with careful precautions, provided that the nurse is not in attendance on any maternity case. A reminder was given, moreover, that a similar conference had been held some years ago to discuss the nursing of measles, which was subsequently undertaken by the district nursing associations without any complaint being made of transference of infection. The view of the council that scarlet fever nursing could be thus arranged has been communicated to the affiliated associations. It was also reported to the meeting that efforts were being made to establish a district nursing service in those parts of the Greater London area within the county of Middlesex which had hitherto been without such provision. The Rev. J. Scott Lidgett announced that certain midwifery training bursaries, to which the trustees of the London parochial charities made grants, were greatly valued, eagerly taken up, and usefully employed. It may be added that the function of the Council is to assemble the various religious, philanthropic, and official interests in the systematization of arrangements for district nursing throughout the metropolis, and to promote its adequacy and efficiency.

#### Courses in Psychology at the Maudsley Hospital.

A new series of lectures and practical courses of instruction for the diploma in psychological medicine will commence at the Maudsley Hospital, Denmark Hill, S.E.5, on March 6th, at 2.30 p.m., when Dr. F. C. Shrubsole will give the first of six lectures on the practical aspect of mental deficiency; they will be continued on succeeding Tuesdays, with the exception of April 10th. A course of eight lectures on morbid psychology by Dr. E. Mapother will be given on Wednesdays at 2.30 and 4 p.m., from March 7th. Dr. A. A. W. Petrie will deliver three lectures on therapeutics on Tuesdays at 4 p.m., beginning on March 20th. Mr. R. Foster Moore will lecture on abnormalities of the fundus oculi on April 16th and 23rd at 2.30 p.m. The first of a course of eight lectures by Dr. Bernard Hart on the psychoneuroses will be given on April 30th, and continued on succeeding Mondays, at 3 and 4.30 p.m. Dr. W. Norwood East will deliver four lectures on crime and insanity on May 1st and the three following Tuesdays at 3 p.m., and Dr. F. L. Golla will give four

lectures on the pathology of mental diseases at 2.30 p.m. on Fridays, commencing May 4th, and followed by four demonstrations of the pathology of the central nervous system by Mr. Charles Geary. Three lectures on the legal relation of insanity and treatment will be delivered by Dr. C. Hubert Bond on Fridays, May 4th and 18th, and Tuesday, May 15th, at 4.30 p.m. Six demonstrations in clinical psychiatry will be given by Dr. E. Mapother on Wednesdays at 2.30 p.m., commencing on April 18th. Dr. F. M. R. Walsho will commence a series of six clinical demonstrations in neurology on Thursday, March 8th, at the National Hospital, W.C.1, at 2.30 p.m. On Thursday, April 18th, at 3 p.m., the first of a series of six demonstrations in neurology by Dr. Golla will be given at the Hospital for Paralysis and Epilepsy, Maida Vale, W. The fee for the whole course is £10 10s. In addition to the special lectures and demonstrations of the course opportunity is provided for clinical work at the Maudsley Hospital. A certain number of whole- or part-time clinical assistantships are also tenable. Further information about the courses may be obtained from the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

## Ireland.

### National Health Commission (Irish Free State): Payment for Medical Certification.

ARISING out of the request of the deputation from the Irish Medical Committee to the National Health Commission for further information with regard to the decision of the Commissioners to change the area of the pool for payment from the dispensary district to the county, the Commissioners have supplied a large amount of tabulated information. In an accompanying letter it is stated:

As explained at the conference the Commissioners have decided that they would not be justified in continuing to use the dispensary area as a basis for calculating the payments for medical certification for the following reasons: (1) As will be seen from the figures in the statements enclosed, the results are obviously unsatisfactory. In the area where the capitation rate is 2s. 8d. the rates per certificate vary from £1 to 3½d. in the March quarter. In the area where the capitation rate is 2s. 1.6d. the rates per certificate vary from 10s. 1½d. to 2½d. in the June quarter. (2) Apart from the financial results shown above, the system is unsatisfactory owing to the fact that it is not possible to obtain accurate figures of the number of insured persons in the dispensary areas without incurring expense which would be very much higher than the results obtained would justify. (3) The calculations on the dispensary basis entail much work and expense in the department, and it is not possible to defend the continuance of expenditure on a scheme which produces such obviously inequitable results. The Commissioners therefore propose that the scheme must be altered, and that in future the unit on which calculations will be based shall be either (a) the administrative county area, or, alternatively, (b) the area in which the capitation rate is uniform.

Dr. Power, chairman of the Irish Medical Committee, in a letter to the Local Medical Committees urging the retention of the dispensary district as the unit for the pool, states that the dispensary medical officer in rural areas treats almost all insured persons, and is therefore in a position to prevent malingering and unnecessary demands on the societies' funds, at the same time protecting his interest in the dispensary pool. Though this does not apply so freely to towns, it is yet a very important and salutary factor. Dr. Power remarks that excessive certification on a dispensary basis can militate only against the interests of those in a small area, and could easily be checked if the Commissioners brought the fact to the notice of the societies operating in the district and to the notice of the Local Medical Committee of the county. However, if those who certify in excess are allowed to go on they will operate only against their own pool. Figures have been presented showing that there has been an increase in the number of certificates issued year by year for some time past. The societies also complain that as a result the demands on their funds are becoming proportionately heavy. Dr. Power agrees that there are reasons why this might be so, but he thinks that the discrepancy between the cost of certificates in different areas

in the same county cannot be attributable entirely to the incidence of disease, or to the properly growing insistence by insured persons on their rights. He suggests that the causes of cheap certification should be investigated in the areas in which it occurs by the Commissioners (who are cognizant of the localities) and the societies, so as to discover the real state of affairs, and apply a remedy if necessary. The certificate values referred to by Dr. Power are from figures supplied by the Insurance Commission, and he gives an instance of a county where Dr. H. (the highest) gets 3s. per certificate, Dr. L. (the lowest) gets 5d. per certificate. The contributions from 414 persons make a certification pool of £50. Now, H. at 3s. per certificate issues 333 certificates annually in respect of 414 insured persons to get that amount, while L. at 5d. per certificate (in his area) to get that amount must issue 2,400. This is a matter for immediate investigation by the societies. According to Dr. Power the county pool idea is not a remedy; it would, if adopted, make things much worse. Thus H. is awarded 3s. per certificate in his district and L. is awarded 5d. per certificate in his district; the county basis is 9½d. Now (he continues) let H. and L., each having issued certificates in respect of 414 insured persons, and therefore drawing £50 each from their respective district, make a common pool equal to £100, and now re-withdraw it on the county basis of 9½d. As it is assumed in the Commissioners' circular, each one will issue the same number of certificates as heretofore, the ratio of certification being H.—1, L.—7.2. In this £100 pool the portion of H. is reduced to £12 4s., and his loss equals £37 16s., while the share of L. becomes £87 16s., with a gain of £37 16s. Where H. got £50 for adequately certifying 414 insured persons each year he now gets £12 4s. for the same service; and where L. certified a similar number for £50 he now gets £87 16s. for the same service. A distribution on those lines is the inevitable result of the adoption of a county scheme. Dr. Power asks: Could the medical profession as a whole support such a grossly unfair proposal? Does it not tend to demoralize those taking part in it? Does it not offer temptation to increase still further the number of certificates each year, and is that fair to the societies? The cost and difficulties of administration are the only objections to dispensary pools which have any substance, and when the Commissioners limit themselves to those points, Dr. Power would be prepared to advise his colleagues to go into the matter with them.

## Correspondence.

### GASTRIC SECRETION OF NEUTRAL CHLORIDE.

SIR,—In reply to the letter of Dr. Gordon W. Goodhart which appeared in your issue of February 25th (p. 325) I should like to state that the evidence which he so much desires has already been fully communicated to the members of the Biochemical Society at their meeting held as long ago as November, 1926.

Corrected proofs of two papers dealing with this work have been returned to the editors of the *Journal of Physiology* some little time ago, and presumably these papers will appear in the next number of the *Journal of Physiology*. The titles of the two papers are: (1) "The factors influencing the concentration of hydrochloric acid during gastric digestion" (MacLean and Griffiths); (2) "Variations in the acidity and total chloride contained in the secretion from an isolated Pavlov pouch in the dog" (MacLean, Griffiths, and Williams). I trust that the evidence contained in these communications will satisfy Dr. Goodhart.

In conclusion I would add that I am not particularly attracted by Dr. Goodhart's reversal of the older custom, generally observed among scientific men, of writing a personal letter before rushing into print. Had Dr. Goodhart written to me directly I would have most gladly furnished him with a copy of the manuscript and any other information I could give him on this subject.—I am, etc.,

London, Feb. 27th.

HUGH MACLEAN.

# "DYSPHAGIA ASSOCIATED WITH ANAEMIA."

SIR,—In their important paper on dysphagia associated with anaemia, published in the *JOURNAL* of February 18th (p. 256), Mr. A. Mason Jones and Mr. Robert D. Owen refer to a case reported by me in the *Guy's Hospital Reports* for October, 1926. I called the condition the "Plummer-Vinson syndrome," as I was not then aware of the earlier work of Brown Kelly and Paterson on the subject. These authors, however, did not mention splenomegaly, and gave no details of the nature of the anaemia present, but they describe in detail the glossitis, which appears to have been overlooked by Plummer and Vinson. In all of the four cases I have now seen, and in the one described by Dr. J. A. Ryle in the *Guy's Hospital Reports* for January, 1927, the characteristic dysphagia was associated with glossitis, non-Addisonian anaemia, and splenomegaly.

It is clear that the dysphagia is not caused by any gross organic disease, but there is no evidence in favour of Plummer and Vinson's view that it is hysterical in origin. The theory that it is due to reflex spasm, which was first suggested by Brown Kelly and Paterson, and which has been followed by Mason Jones and Owen, has much to be said for it; but, although I adopted it in my paper on the subject, I am now inclined to think that any spasm which is present is secondary, the primary cause being achalasia of the pharyngo-oesophageal sphincter of Nages, the condition being exactly analogous with achalasia of the cardiac sphincter, which was formerly erroneously described as cardiospasm. Achalasia of the cardia has now been proved, by the pathological investigations of Stokes and Rake<sup>1</sup> to be due to inflammatory and degenerative changes in Auerbach's plexus, which prevent the normal relaxation of the sphincter when it is reached by peristaltic waves carrying food down the oesophagus. If similar changes were present in Auerbach's plexus at the upper sphincter, relaxation at the beginning of the act of deglutination would be prevented. Such changes could readily be caused by a direct spread of inflammation from the mucous membrane to the deeper-lying plexus. There can be little doubt that the atrophic glossitis and pharyngo-oesophagitis present in these cases is a result of a streptococcal infection, which is also responsible for the anaemia and splenomegaly. Dilatation of the closed pharyngo-oesophageal sphincter gives relief, just as the passage of a mercury tube is the most effectual treatment of achalasia of the cardia.—I am, etc.,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, Feb. 22nd.

## COLLECTIVE INVESTIGATION AND TUBERCULIN.

SIR,—From time to time throughout the course of the last thirty-seven years, since the first announcement by Koch of his discovery of an agent which would prevent the development of tuberculosis in animals, and arrest the disease if present, the *BRITISH MEDICAL JOURNAL* has consistently viewed and reviewed the available evidence fairly and hopefully, and one is struck by the sustained interest and balanced judgement brought to bear, throughout this long period, on a subject agitated by the greatest variations of opinion and by the ebb and flow of prejudice of every description.

Yet notwithstanding the critical examination of the reports available up to date, it still remains for you to ask, so recently as July, 1927, "To what extent is tuberculin of value in the diagnosis and treatment of tuberculosis?" and to remark that "practitioners feel that they are without guidance as to the cases in which, and the conditions under which, tuberculin is of value; guidance to which they are entitled the more, since systematic treatment by tuberculin is advocated by medical men with experience of its value."

It appears to me that the guidance asked for demands a thorough re-examination of the whole basis of the subject; that is to say, a reinvestigation into the course and results of cases treated in accordance with Koch's own final conclusions and directions. Discarding the pre-

liminary conceptions of 1890, except in relation to diagnosis, such a re-examination would involve an inquiry into the action of T.R. (1897) and B.E. (1901) in such cases, and with the observance of such directions, as Koch himself laid down, undertaken after a thorough and minute examination of and acquaintance with the whole of Koch's work on the subject. Extraordinary as it may appear, adequate clinical examination of Koch's important work on this subject has not yet been accomplished; certainly it has not been accomplished to such purpose as to carry conviction to medical opinion in general, though one may note your opinion, stated in 1911, that "already results were accumulating which should convince everyone but the incurable sceptic."

The recent revival of a former ideal of the British Medical Association—namely, the direction of the collective scientific acumen of its members towards the solution of important medical questions—together with the failure of other bodies to deal adequately with the subject, induces me to appeal to the Association to undertake this important work itself. There is sufficient individual initiative and knowledge to set on foot here and there, in this Division or that, collective research upon a sufficient number of suitable cases, under suitable conditions, for a sufficient length of time, and under the scrutiny of competent observers, and so to furnish, or assist in furnishing, within a few years, some satisfying answer to the urgent and insistent questions which are now being asked.

In this case collective investigation might well begin with the Divisions themselves, leaving collation and co-ordination to develop from a natural tendency to correlate the work as it progresses. No rigid uniformity of procedure need be insisted upon; the issue is a fairly simple one. It is to demonstrate the effect of rapidly increasing doses of T.R. or B.E., administered in accordance with Koch's methods, in simple, early, uncomplicated cases of tuberculosis, especially such as present lesions whose progress is capable of being watched by actual inspection.

The obstacles in the way of private investigation are almost insuperable, owing to the impossibility of inducing a sufficient number of suitable cases to undergo a long tedious course of treatment, often at the mercy of every idle opinion. In collective investigation there would be scope for a selection of suitable cases from a wide field, observation by trained observers, and the building up of a solid body of common knowledge and instructed opinion, with all the weight which such a settled body of opinion would exercise.

Judging from considerable experience, I have very little doubt as to what the verdict would be, and if this important work is to be retained to any extent in the hands of the general practitioner, instead of those of the specialist or State official, the method here advocated would form an invaluable means of diffusing knowledge on a line of work which is far removed from ordinary methods of practice.

In any case, the present range of applicability of tuberculin is already wide, the possibilities of the subject are of universal importance, and further demonstration and research are of extreme urgency.—I am, etc.,

Wandsworth, Feb. 23rd.

ROBERT CARSWELL.

## SHOCK AND ABORTION.

SIR,—One kind of shock referred to by Mr. Paramore in his interesting letter in your columns to-day (p. 327) appears to be that which Brouardel in his lectures (translated under the name of *Death and Sudden Death*) calls inhibition.

There is no doubt that death by inhibition is intimately related to the mental state of the patient at the time of the reception of the trauma, whatever it may be. Equally—or perhaps it is really the same thing differently stated—death by inhibition is particularly likely to occur in connexion with injury or offence to particular organs or regions. Again, personal idiosyncrasies and varieties of constitution have to be borne in mind. But one is more and more convinced of the paramount importance of the patient's psychological state at the moment of the trauma. Fear, shame, and the like count for much; the unexpectedness of a trauma counts for much; and, singularly but

<sup>1</sup> Vide *Guy's Hospital Reports*, lxxvii, 141, 1927.

indisputably, he or she who is "keyed up," to receive an injury or lesion that is feared and dreaded *without displaying emotion* in the ordinary way, is very likely to suffer from inhibition. Again, associations come into play. I knew once a very brave and gallant soldier who fainted to disappearance of his pulse whenever an attempt was made to vaccinate him. There had been distressing circumstances attendant on his first vaccination.

Some discussion on these and other aspects of the question of shock (including that of delayed shock) took place at a meeting of the Medico-Legal Society in, I think, 1913, and is duly recorded in the *Transactions* of that body.—I am, etc.,

London, W., Feb. 25th.

F. G. CROOKSHANK.

### MEDICAL EXAMINATIONS FOR LIFE ASSURANCE.

SIR,—The more cases one examines for life insurance the more one becomes convinced that the medical profession, as a whole, unnecessarily wastes probably thousands of hours per annum which, with a little help from the insurance companies, could be easily avoided.

Everyone who does this work must have been struck by the difficulty that practically all proposers for life insurance have in answering questions concerning family history. To be asked suddenly to give the age of father, mother, and perhaps several sisters and brothers, when these are living, is often a question requiring time for thought. When, however, several of these people have been dead many years it becomes increasingly difficult to answer correctly their age at death, the year of death, and what precisely was the cause of death.

Some companies realize this difficulty and forward these details on a printed form, which the proposer has had time to consider previously, thus saving, in some cases, five to ten minutes' concentrated thinking and arithmetic in the examiner's consulting room, with a possible negative result.

The other factor which leads to waste of time is the lack of knowledge on the proposer's part that he will have to pass a specimen of his urine in the presence of the examiner. My experience is that the last act of almost everyone before presenting himself for medical examination is to empty the bladder, so that if he should be able to pass urine there is rarely enough to take the specific gravity without dilution. I have found that the companies for whom one examines many cases are quite willing to have the family history details sent with the proposal papers, or with the medical examiner's form. It is the sporadic cases which take up so much of one's time.

To overcome these annoyances would be an easy undertaking for the Central Office of the British Medical Association, and I feel that the profession would be deeply obliged to them for doing so. The insurance companies, I am convinced, would be willing to help. All that would be necessary is an undertaking on the part of each company to provide the proposer with a copy of the family history details, to be filled in before coming for examination, and to tell him that he will need to provide a specimen of urine, passed in the presence of the examiner. Women would be told to take a specimen in a bottle.—I am, etc.,

W. M. ROSSON, M.D., F.R.C.P.

Northampton, Feb. 20th.

### SPECIALIST PUBLIC HEALTH SERVICES.

SIR,—Your leader in the *JOURNAL* of February 11th (p. 228) commends the appointment of district medical officers of health who are also school medical officers, maternity and child welfare officers, and tuberculosis officers under the county council (so-called omnibus appointments). While we all believe it is an advantage to the service that these officers should be under the county councils, and recognize that the appointment provides, as you suggest, "an escape from the backwaters of the health service," there is yet another aspect of the matter, where tuber-

culosis is concerned, which deserves attention. Such an officer would almost essentially be a junior, and without much clinical knowledge of tuberculosis. To diagnose and above all to advise as to the treatment of tuberculosis necessitates prolonged experience and training, and a man of less capacity could not inspire the confidence of the general practitioner, without which the tuberculosis campaign is almost impossible; most of the practitioner concerned would be more competent to diagnose and treat tuberculosis than the officer appointed.

Surely the solution of the tuberculosis problem lies in the appointment of consultant officers of wide experience covering an area large enough to afford adequate remuneration for whole-time men, together with modern aids in diagnosis and treatment. The value of the additional appointment of a part-time consultant, as in some districts is small, for he will not obtain the same personal contact with practitioners as the whole-time officer.—I am, etc.,

Paignton, Devon, Feb. 22nd.

E. WARD.

### EDINBURGH CORPORATION BILL.

SIR,—We notice that a statement is made in your report of the meeting of the Parliamentary Medical Committee on February 21st that "The discussion, which lasted about an hour and a half, showed that the Parliamentary Medical Committee was united in support of the objects of the bill. . . ."

We submit that this is a travesty of what occurred at that meeting, if we understand the language your Parliamentary correspondent uses. The objects of the bill, as set out in the pamphlet conveying the case for the corporation, are to secure compulsory treatment both of defaulters who discontinue treatment before official discharge and of persons who are suspected of infection, but who have not sought treatment. A large majority of members present spoke against these objects very definitely.—We are, etc.,

E. GRAHAM LITTLE,  
RICHARD H. LUCK,  
A. VERNON DAVIES,  
ALFRED SALTER,  
THOMAS WATTS.

House of Commons, Feb. 24th.

\*\* Our Parliamentary correspondent regrets that the sentence objected to by the signatories to the above letter did not convey clearly the idea he wished to express—that is, that the aim of the bill is to secure that persons who break off treatment at venereal disease clinics shall be induced to resume it till they are innocuous.

### TREATMENT OF ACUTE PNEUMONIA.

SIR,—Dr. Maidlow's letter in the *JOURNAL* of February 11th (p. 238) cannot be allowed to pass unchallenged. It breathes the spirit of a bygone age—an age of frock-coats, top-hats, dandereary whiskers, and ponderous platitudes. The days of adopting a line of expectant treatment and hoping for the best have had their innings, and must make way for rational treatment. Bulky volumes of therapeutics are of very little help when one gets down to bed-rock facts. Where one does receive much help is in the *Letters to the Editor*, *Notes and Queries*, and the small print generally in the *BRITISH MEDICAL JOURNAL*.

Dr. Maidlow speaks well of champagne, rum, and cider in the treatment of pneumonia—he likes his comforts—but sodium nucleinate is good, potassium permanganate better, and collosol manganese best of all, even though it does tickle the buttocks. No man with any initiative can stand by and persuade himself that he is doing the best for his patient by filling him up with expectorants, cardiac stimulants, and alcohol. I have used potassium permanganate for a sufficiently long period to be convinced of its great value in most of the commoner constitutional diseases, and collosol manganese has displaced, in my hands, messy poultices and fomentations.

It is very easy for an experienced practitioner to get into a rut, and very difficult for him to get out of it. Ho

has been treating a disease by one method for twenty years, and continues to use the same method for the next twenty. This should be discouraged, otherwise we should still be treating diphtheria with ipecacuanha wine and leeches.

This is an era of restlessness and of research, and we must not rest content until we have pneumonia under control, in much the same way as we have, say, diphtheria. I may be as a voice crying in the wilderness, "Make straight the curve on the temperature chart"; but we must do it, or our labours are in vain.—I am, etc.,

Dennistoun, Glasgow, Feb. 18th.

H. L. McCORMICK.

### THE ACUTE ABDOMEN.

Sm,—It is unfortunate when those who know what they are talking about suffer from an incapacity to impart their knowledge.

I happened on Mr. Rankin's letter before reading Mr. Flint's lecture. From Mr. Rankin I gathered that Mr. Flint depended on the "classical symptoms" (including faecal vomiting) for the diagnosis of intestinal obstruction; that Mr. Rankin had knowledge of earlier signs, which he kept secret; that a rising pulse rate was the surest indication for laparotomy.

It was not clear whether Mr. Rankin made his diagnosis and waited for the pulse rate to rise, or operated on all patients with rising pulse rates (in the latter case may the fates protect Mr. Rankin from a diaphragmatic pleurisy with pneumonia). I further gathered that Mr. Flint recommended high enemata and other non-operative treatment for intussusception, Richter's hernia, etc.; also that cases suspected of acute abdominal conditions may be observed by properly trained competent surgeons, never by general practitioners, nor, apparently, by Mr. Flint (in the opinion of Mr. Rankin).

My curiosity was aroused, and I turned to the paper of this reactionary Mr. Flint. I was puzzled to find no reference to high enemata in treatment, though there was a statement of the diagnostic significance of their results. As to faecal vomiting, there was merely the statement that it had "no useful place in diagnosis." In place of the opium, bleeding, and blisters that I had expected was the astonishing advice, "the earlier operation is performed the better."

Perhaps Mr. Rankin may find time to read this interesting lecture again, with care, and to supplement its deficiencies in a constructive manner by divulging his own methods for the early diagnosis of these dangerous diseases from the many other cases of vomiting and abdominal pain that are almost the daily experience of the general practitioner, but seldom reach the operating surgeon.—I am, etc.,

Chingford, Feb. 21st.

E. BILLING.

Sm,—Mr. Flint has evidently read my letter with less care than I gave to his article. He must not do himself the injustice of thinking that his name and reputation have not reached Glasgow. The note of disappointment sounded in my letter was based on the fact that in a paper given by one who knows what he is talking about so much classical chaff should obscure the valuable grains of his personal experience.

His statistics and those of "G.P." in your issue of February 25th (pp. 325 and 326) amply confirm my thesis that practitioners brought up on the classical clinical symptomatology of the moribund will continue to look, and look till it is too late, in cases of intestinal obstruction—the most deceptive of all the types of the acute abdomen.

Hourly observation of the pulse-respiration and pulse-temperature ratios as a guide to exploration in every case of abdominal discomfort or pain associated with nausea or vomiting should certainly be routine practice. Can the profession as at present organized do it?

I salute Mr. Jeans and trust that our abdominal expansions will always synchronize with our chest expansions.—I am, etc.,

Glasgow, Feb. 26th.

WILLIAM RANKIN.

### Obituary.

F. D. BENNETT, M.R.C.S., L.R.C.P.,  
London.

Dr. FRANCIS DILLON BENNETT, who recently died, was born in Sydney, Australia. He came to England in 1878, and after studying medicine at St. Bartholomew's Hospital obtained, in 1880, the diplomas M.R.C.S., L.R.C.P., and L.S.A. In addition to conducting a private ophthalmic practice he was for many years medical officer to the Army and Navy Co-operative Society.

Dr. Bennett was associated with the Royal Eye Hospital for more than thirty years, being senior clinical assistant to Sir William Collins. His knowledge of ophthalmology was very thorough, and both in refraction work and in ophthalmoscopic diagnosis his judgement was sound and reliable. He served for a considerable period on the board of management of the hospital, where his sagacious advice and equable temper often helped to smooth out difficulties and to increase the reputation of the institution. During the war he acted as consulting ophthalmic surgeon to the Anglo-French Red Cross Society, and was created a Chevalier of the Legion of Honour and received the Médaille Reconnaissance Française; he was also awarded the medal of the British Red Cross.

Dr. Bennett took an active interest in the work of the British Medical Association. He was honorary secretary of the Westminster Division from 1918 to 1923, a member of the executive committee from 1922 to 1927, and vice-chairman in 1926. He was also a member of the Metropolitan Counties Branch Council from 1918 to 1926.

A colleague writes: As one for whom the death of Dr. F. D. Bennett has brought to an end a close friendship covering over forty years, I am expressing the feelings of a host of people to whom the end of his well-spent life has brought a deep sense of personal loss. He had a positive genius for friendship, making friends wherever he went and retaining their affection to a remarkable degree. Quiet, reserved, and grave in manner, he seemed to most people on first acquaintance kindly rather than warm-hearted, but it did not take long for them to realize that he was one of those rare spirits for whom the joys and sorrows of others are of far greater importance than their own. He shared the troubles and anxieties of the many friends who sought his advice on every conceivable subject. None was ever sent empty away, and his sound judgement rarely failed to solve their special problems. Not often is a man found of whom it can honestly be said that he was universally respected, at the same time capable of winning the affection of all with whom he was brought in contact; but it was so with "Ben," as he was known to his intimates all through his life. Greatly beloved and deeply mourned by all who knew him, his passing leaves a gap in many lives.

Dr. HARVEY HILLIARD (formerly chairman of the Westminster Division) writes: By the death of Dr. F. D. Bennett the British Medical Association in Westminster loses a staunch supporter and the medical profession a confrere who set the highest professional example. For several years he acted as secretary of the Westminster Division, and did his best to bring together the medical men in the district in a spirit of friendly co-operation. Bennett was a man whose kindness of heart was one of his chief characteristics, and gained for him the affection of all who knew him.

T. C. GUTHRIE, M.B., C.M.,  
Tunbridge Wells.

We regret to announce the death, on February 18th, of THOMAS CLEMENT GUTHRIE of Tunbridge Wells in his 61st year. Dr. Guthrie was born at Liberton in Midlothian, and received his medical education at the University of Edinburgh and St. Thomas's Hospital. He graduated M.B., C.M.Ed. in 1892, and obtained the diplomas M.R.C.S., L.R.C.P. five years later. He held the appointments of house-surgeon at the Edinburgh Royal Infirmary and the Royal Hospital for Sick Children, and was assistant physician to the Victoria Dispensary for Diseases of the Chest. Some thirty years ago he settled

Mr. Kidd said he was suspicious of the Minister's reference to the extra cost incurred through increased sickness. Last year Scotland was still suffering from the coal stoppage, and had the wettest season on record. The weather, acting on vitality lowered after the stoppage, accounted for the increased sickness. He asked the Minister to be slow in assuming that medical practitioners had been too facile in allowing panel patients medical treatment, or too slow in turning them off the list. If they interfered with the discretion of the doctor, on whom was the supervision to rest — on official medical men representing the Ministry, or should the doctor have the assistance of other panel doctors? He had found cases where a doctor objected to being overruled on the quality of the medicine which he prescribed. They should not create the impression that there were two classes of patients, only one of which received certain medicines even though they were equally necessary to the other. Mr. Seryngeour did not think there was any ground for saying that the doctors were slack in attending to the interests of the patients or of the approved societies. He had not for some time heard a complaint in Scotland that a doctor had more than the maximum number on his panel. Mr. Campbell Stephen said the working classes frequently complained that the doctors were far too particular in certification. Very often these poor people were sent back to work when, if they had been members of the middle classes, they would still have been receiving every medical attention and the best of treatment. Because they happened to be poor people the doctors insisted that they should go back to work. Nevertheless, the Minister was now going to bully the doctors, though he had no evidence to show

that medical men in Scotland were not acting properly in this matter. The House should think seriously before it allowed the Secretary for Scotland to impose new conditions on the medical profession in order that they might send working people to work when they were unfit. He asked why in Glasgow there had not been the regular election for the medical panel committee. Medical men in Glasgow had pressed for the election, yet the Minister refused to have it. Mr. Duncan Grunlan said he made no charges against doctors. He did not think they would find an instance in Lanarkshire, where a medical practitioner had signed a "lino" for the payment of health benefit to a person not entitled to it.

Sir Henry Cauley said the increase in sickness and disablement benefit in the last three years had been very serious. In numerous instances the doctor's desire to do his duty had brought him in conflict with his patient. The cure was to increase his independence. In many cases a panel doctor was approached by the father of a household and might be slow in certifying him as unfit for work or to receive benefit. The patient changed to another panel doctor, and the old panel doctor, who had been attending the man's wife and child in his private practice, lost that connection. That ought not to be allowed to arise. As much as a month should elapse before a patient could change his panel doctor. Mr. Westwood alleged that in his constituency (Peebles and Southern Midlothian) medical men were forming themselves into a limited liability company so that they could dispense the medicines which they themselves had prescribed. The original Health Insurance Act laid down that, save in exceptional cases, a medical man should not dispense the medicine he prescribed, but he could instance a case where a doctor had started a shop company, in which his wife took two shares and he the rest. This doctor did not hand prescriptions over to the patients, but took them away to dispense himself. He hoped the Secretary for Scotland would issue instructions that prescriptions must be given to insured persons so that they might obtain medicine from whatever chemist they chose.

Sir John Gilmour, speaking again, said that in 1925 the number of national health cases in Scotland on which doubt was expressed and which were referred to examination was 22,231. It was 24,016 in 1926 and 35,068 in 1927. Of men's cases examined by the referee in 1927 the practitioner's certificate was upheld in 45 per cent., and of women's cases in 35 per cent. The practitioner's certificate was reversed in 21 per cent. of the men's cases and in 24 per cent. of the women's. Of cases referred but not examined, 15 per cent. of the men were declared off the fund and 19 per cent. of the women. Of the men 14 per cent. failed to appear and of the women 19 per cent. There were not examined, for various reasons, 5 per cent. of the men and 3 per cent. of the women. If the cases were genuine the doctors had full right to make their recommendations. The Board had issued an order by which fourteen days' notice of change must be given. The object was to let the doctor feel that there was a time during which the fairness of his decision might be considered by himself and the referee. He had found it necessary to say quite plainly that some members of the medical profession were not observing as carefully as they should the duties laid on them. One must recognize the difficulties under which many of these cases were dealt with, but the fact remained. He hoped the medical profession would help the Board and the societies concerned, and that they should not be compelled to take more compulsory methods. He did not think a Select Committee was required to inquire into the charges he had made. The facts were patent and known to the approved societies, to the House, and to the medical profession. Replying to questions put during the debate, Sir John said election to the medical panel had not been proceeded with as there was a doubt as to whether it would be continued in view of a recommendation of the Royal Commission. He would investigate Mr. Westwood's allegations regarding dispensing by practitioners if that member would send him information. Mr. William Adamson protested against the diversions of money from housing. The Supplementary Estimate was carried by 229 to 69.

#### Qualifications in Ophthalmology of Medical Officers.

Sir John Gilmour, replying on February 22nd to Sir R. Hamilton, said that on appointing medical officers to their staff the Scottish Board of Health did not require candidates to possess special qualifications in ophthalmology other than the course now obligatory in the medical curriculum. But the majority of the present staff had had special experience in eye work, and in view of the special conditions of industrial blindness the whole medical staff had undergone a course of instruction by a consultant ophthalmologist directed to the peculiar problems arising under the Blind Persons Act. When cases presenting exceptional difficulty were reported, the Board authorized the employment of an eye specialist.

#### Small-pox.

Answering Mr. Rhys Davies, on February 23rd, Mr. Chamberlain said that in the present year five cases of small-pox had occurred in the Hindley urban district, and four in the Aspull urban district. The sources of infection had not been ascertained. He detailed the preventive measures taken. Absentees from works were visited. Picture halls, employment exchange, and post office and The schools, billiard halls were closed for matinee performances. were also disinfected. He was advised that overcrowding and bad sanitation did not cause outbreaks of small-pox.

Answering Mr. Groves, on February 23rd, Mr. Chamberlain said that of the 7,956 persons classified in the report of the chief medical officer of the Ministry of Health for 1925 as unvaccinated, 459 had been vaccinated during the incubation period, 72 of whom were over the age of 20. He did not think the added information would justify him in giving instructions that in filling up forms

giving details of small-pox cases the responsible officials should state whether the case was vaccinated during the incubation period.

On February 27th Mr. Chamberlain, replying to Mr. Groves, said that the notifications of cases of small-pox in England and Wales last year were as follows, the figures being provisional: In the thirteen weeks ended April 2nd, 1927, 6,153 cases; in the thirteen weeks ended August 2nd, 3,753 cases; in the thirteen weeks ended September 1st, 1,930 cases; and in the thirteen weeks ended December 31st, 2,928 cases. This made a total for the year of 14,764 cases.

On February 28th Sir Kingsley Wood informed Mr. Groves that he had seen a report of the proceedings at the coroner's inquest on the death of Mr. J. H. Chetter of Warrington, after vaccination imposed on him by his employers as an alternative to suspension from work for an indefinite period. Representatives of the Ministry of Health were not present at the post-mortem examination or at the inquest, and the vaccination was not carried out by a public vaccinator with Government lymph.

Replying to Dr. Vernon Davies, on February 28th, Sir Kingsley Wood said that during 1927 there were 49 deaths in respect of which small-pox was entered on the medical certificate as the cause, or one of the causes, of death; 2,582 cases had been notified during the first seven weeks of the present year, but no particulars on deaths were available.

#### Foot-and-Mouth Disease.

Mr. Guinness, replying to Mr. Hurd on February 27th, said that in March, 1927, the Ministry of Agriculture asked three of the Governments of South America which exported meat to this country to accept certain proposals designed to prevent the introduction of virus of foot-and-mouth disease into Great Britain. Last December Lord Bledisloe, then Parliamentary Secretary, conferred with representatives of the Argentine, Uruguayan, and Brazilian Governments. As a result, the Argentine Government issued a decree, which took effect on February 1st, the main provision of which was that the carcasses of infected animals, and those which had been in immediate contact with them, should not be exported to Great Britain. The Uruguayan and Brazilian Governments had adopted similar regulations. Lord Bledisloe reported that all three Governments were increasing their efforts to get foot-and-mouth disease under control. A British inspector, who was stationed in the Argentine Republic, reported that the disease was endemic. In a second progress report the Foot-and-Mouth Disease Research Committee had reported that in two instances the bone marrow in carcasses of experimentally infected animals, which had been frozen or chilled for seventy-six days, remained infective. There was thus experimental evidence that chilled or frozen carcasses of infected foreign cattle might introduce disease to this country, but there was no conclusive evidence that this happened under ordinary trade conditions.

#### Washington Convention on Hours of Labour.

In Committee of Supply on the Civil Service Estimates, in the House of Commons on February 27th, Mr. Shaw moved a reduction of £100 in the salary of the Minister of Labour to call attention to the failure of the Government to ratify the Washington Hours Convention. Mr. Betterson, Parliamentary Secretary to the Ministry of Labour, said that to accuse this country of deception because the Government had refused to accept as final a draft which, if ratified, would cause injury to hundreds of thousands of workers in this country was to ask them to adopt an action quite inadmissible and inexcusable. The British Government did not ratify because there were at this moment agreements in existence affecting many hundreds of thousands of British workers. Those agreements were valuable instruments in the maintenance of industrial peace and would be improved by ratification.

Dr. Vernon Davies said that there had been one great feature in the debate which had made it different from all the previous debates to which he had listened. That was that to-day the Government, by means of the Parliamentary Secretary, had made some attempt to controvert the charges laid against them. It was a peculiar thing that both the Labour party in wishing for ratification, and the Conservative party in opposing it, said that they did it in the interests of the workers. Both sides could not be right. Unfortunately, up to the present, the Government had not convinced him as he would like to be convinced. He was pleased that the Parliamentary Secretary had made certain specific statements which would be of the greatest possible value to the working people when they read and digested them. The fact first was that the right of Parliament was supreme. The fact that delegates were sent to Washington to ratify the Convention did not necessarily mean that the Government were compelled to give effect to the ratification. Another point well brought out was that the Convention must be ratified as a whole and not in part, and that was one of the reasons why the Government had not accepted it. A further point was that other nations had also the habit of not always ratifying the conventions made by their delegates. He wished to impress on the Minister of Labour that this question of the forty-eight hours week was a very vital one to the working people of this country. It was the one thing on which they had concentrated. They held the opinion that they had won the forty-eight hours week only by prolonged and bitter fights, and they were determined that in no circumstances short of very dire necessity would they ever give it up. What the Government had not quite convinced them of was that the non-ratification of this Convention was to the advantage of the workpeople of this country. If the Minister would give specific instances and simply say that if the Convention were ratified it would mean that the textile workers would be

working forty-eight hours a week with no overtime, but that in Germany they would be working, say, fifty hours, or sixty in Czechoslovakia, and so on, such a statement would carry conviction. Up to the present the Government had not been able to prove conclusively to him that ratification would be definitely to the detriment of the people, and he was compelled for the fourth time to speak against his party. He hoped the Minister would be able to make a strong case in proof of the statement that ratification would be detrimental to the workpeople and industry of the country, and that the Government regarded it as their duty, in looking after the workpeople's interests first and foremost, to refuse to ratify the Convention.

Sir A. Steel-Maitland expressed the hope that the employers' representatives and the Trades Union Council would sit down with him and help in the revision of the Convention, and work out a practicable scheme.

The motion for the reduction of the vote was defeated.

#### *Reorganization of Offices (Scotland) Bill.*

On February 28th Sir John Gilmour moved the second reading of the Reorganization of Offices (Scotland) Bill. The bill provides that on the appointed day the Scottish Board of Health, the Board of Agriculture for Scotland, and the Prison Commissioners for Scotland shall cease to exist. The powers and duties of these Boards, including the Prison Commissioners for Scotland, are to be transferred to and vested in a Department of Health for Scotland, a Department of Agriculture for Scotland, and a Prisons Department for Scotland, under the control and direction of one of His Majesty's Principal Secretaries of State, and consisting of a secretary and such other officers and servants as the Secretary of State may determine. The offices of the departments are to be situated in Edinburgh. The persons employed by the Board are to be transferred and attached to the department, and shall be in no worse position as regards tenure of office, salary, and superannuation allowance than if the bill had not passed. No vacancy in the office of members of the Scottish Board of Health existing at the passage of the bill or afterwards is to be filled, and that part of Section 3 of the Scottish Board of Health Act, 1919, requiring that the Board of Health shall at all times include certain members having the qualifications therein set forth, is to cease to have effect.

Sir John Gilmour said that the bill was practically identical with that of last year. While it abolished patronage, the bill did not lessen the possibilities of contact between outside interests in Scotland and the departments. The sole motive was one of efficiency. The bill left intact the same responsibilities, and it gave to the Minister in charge in the House of Commons additional assistance in that, in future, he would have the valuable advice of first-class civil servants. There was no intention of transferring the work of the departments to London, and to make that clear he had inserted a provision in the bill to the effect that the offices should be in Edinburgh.

Mr. T. Johnston moved the rejection of the bill, and contended that although the offices would be in Edinburgh, the power that directed the departments would be in London. The Government were deliberately attempting to take away the administration of public affairs in Scotland from skilled men selected because of their specialized knowledge, and transfer it to men who, whatever scholastic qualifications they might have acquired at Oxford or Cambridge, had not proved their fitness to control the departments. Mr. Barr seconded the rejection. Mr. Webb urged the Government not to smother the real experts in these departments by administrative chiefs. He admitted that it would be to the advantage of the Minister to have an administrative chief in each department. Mr. Kidd said that from his experience in the Board of Health there was probably no better service than that which had obtained in Edinburgh. There was, however, a great deal to be said for concentrated administration of the public service in the hands of the Civil Service.

The debate on the second reading was adjourned, and will probably be completed on March 5th.

**Pensions.**—On February 23rd Major Tryon issued figures showing that during 1927 the Ministry of Pensions employed 50 established whole-time medical officers and 190 unestablished ones, against 50 and 222 respectively in 1926, 50 and 329 in 1925, and 3 and 452 in 1924. In 1927 the average number of ex-service men receiving treatment was 27,700, against 34,700 in 1926, 44,600 in 1925, and 56,500 in 1924. The weekly cost of an ex-service patient in a Ministry of Pensions institution during 1927 was £3 0s. 3d., and of similar patients in other hospitals £2 18s. 7d. each. At the end of January, 1928, 5,300 ex-service men in England and 800 in Scotland were receiving, at the expense of the Ministry, treatment in institutions belonging to local authorities. Lieut.-Colonel G. F. Stanley, replying to Mr. Robinson on February 28th, said that the occasions which necessitated a visit by a medical officer of the Ministry of Pensions to a patient's home were comparatively few, and it had long been the practice of the Ministry to employ a medical man on a fee basis in the rare cases where the deputy commissioner of medical services was not able to visit the case with reasonable promptness. Discharge of patients under the arrangements made in connexion with the arrangements, had normally the services of their own medical officers available to call for purposes of treatment at home or otherwise, and the Minister of Pensions would not be justified in duplicating those arrangements.

**Tetra-ethyl Lead.**—The Home Secretary, in an answer on February 23rd to Commander Kenworthy, said the effect on the public health of the use of petrol diluted with tetra-ethyl lead was outside the jurisdiction of the Home Office. However, as

special measures might have to be taken for the protection of factory workers, that department had followed closely the investigations made in the United States. No evidence had been discovered there of any injury to the public. No regulations had been imposed in the United States on the use of this substance, but instructions were issued by the company supplying it, and the same was done in this country. The effect on workers in industry where there was a risk through exposure to tetra-ethyl lead would be carefully watched. So far no case of lead poisoning had occurred. He had seen a recent warning by Sir William Pope against its use. He would confer with the Ministry of Health to see whether the Department of Scientific and Industrial Research could investigate the matter more fully. Commander Kenworthy asked whether the Home Secretary would consider the effect of this substance in city thoroughfares. Sir W. Joynson-Hicks said the Ministry of Health dealt with public health. Colonel Howard Barry asked whether the Home Secretary knew that lead poisoning took a considerable time before it appeared. No answer was returned.

**Notifiable Diseases.**—Replying to Lord Sandon, on February 23rd, Mr. Chamberlain said the majority of infectious diseases were notifiable throughout the country, but a few had been made notifiable in certain areas only of London and the provinces for reasons which did not exist elsewhere. Nothing would be gained by uniformity.

**The Mosquito Pest.**—In reply to questions about the prevention of mosquitos in England, Mr. Chamberlain said the indiscriminate spraying of all marsh lands was not necessary and would probably be ineffective. He advised local authorities, when they had any particular pest, to apply to the Ministry of Health, which could send an expert to advise. A British Museum pamphlet on *British Mosquitos and Their Control* contained advice on the best methods to combat mosquito pests.

**Leprosy.**—On February 27th Mr. Amery, in reply to a question, said that in those parts of the Empire where leprosy existed active measures were being taken by medical departments for its control, in many cases in co-operation with the British Empire Leprosy Relief Association and other agencies. Medical officers trained in recent methods had been detailed for special duty in Nigeria, the Gold Coast, Fiji, and other colonies, while in all areas attention was being given to the possibility of the eradication of the disease by the establishment of treatment stations, as in Tanganyika, Nyasaland, Uganda, or by such other means as the situation demanded.

**Night Work by Boys in Mines.**—Commodore King, replying to Mr. Lee on February 28th, said he was aware that many of the 28,000 youths between 14 and 16 working underground in the collieries were expected to work on the night shift, and that youths of a similar age were not allowed by law to work on the surface at night. Medical examination was the practice at some collieries, but was not compulsory by law. In 1911, when Parliament passed the Coal Mines Act of that year, it was decided that the prohibition against night work by boys on the surface should not be extended to underground work, and this decision was confirmed by the Washington Convention of 1919 and by the Employment of Women, Young Persons, and Children Act of 1920. He was not aware of any sufficient reason for reversing this decision.

**Closing of Military Hospitals.**—On February 28th, in reply to Dr. Vernon Davies, Sir L. Worthington-Evans said that in 1922 the Military Hospital, Chatham, and the Royal Naval Hospital, the Military Hospital, Chatham, and the Royal Naval Hospital, were closed. Military patients at Chatham were now treated in the Royal Naval Hospital, Chatham, and naval sick treated in the Royal Naval Hospital, Chatham. Since the Alexandria Military Hospital at Cosham and the Military Hospital at Devonport had been closed, and military patients in these districts were now treated at naval hospitals. The Joint Medical Services Committee had the question of co-operation between the three medical services continually under review, and useful work was being done.

**Humane Killing of Animals.**—On February 17th General Charrles moved the second reading of the Slaughter of Animals (Scotland) Bill, to provide that in all Scottish slaughterhouses and knackers' yards the slaughtermen shall be duly trained and licensed, and shall, for all animals except swine, use a mechanical instrument. Colonel Moore said that over 2,000,000 animals were slaughtered yearly in Scotland. The bill was read a second time by 118 to 11, and sent to a standing committee. On February 16th Mr. Chamberlain said he did not see his way to introduce legislation to enforce the universal use of the humane killer in slaughterhouses.

**Inspection of Offices.**—On February 27th Mr. Chamberlain, in reply to Dr. Fremantle, said that he advised local authorities, on inquiry, that they had powers to undertake systematic inspection of offices as well as to inspect on complaint. He had not had any instance brought to his notice where a local authority had been impeded in such inspection.

#### *Notes in Brief.*

Mr. Chamberlain does not propose to issue a general instruction to hospitals under his control advising the provision of special beds for abnormally tall patients.

On February 1st, 1928, 50,556 houses were building under the Housing Acts and 95,205 more were authorized.

No case of foot-and-mouth disease has been definitely traced to imported agricultural or garden produce.

In the opinion of the Home Secretary it is too early to form an opinion on the efficacy of the regulations which came into force last October under the Lead Paint Act, 1926.

In the Admiralty hospitals of the United Kingdom 1,912 beds are available; the maximum number occupied on any day last year was 1,804. For Air Force hospitals the figures were 440 and 368.

Excluding lunatics, casuals, and persons only receiving domiciliary medical relief, 1,208,179 persons were receiving poor relief in England and Wales on February 4th, 1928.

On March 31st last 14,563 blind persons between 50 and 70 years of age were receiving pensions under the Blind Persons Act, and there were approximately 10,000 blind old age pensioners over 70. On the same date there were in England and Wales 258 blind children under 5 years of age and 2,554 between 5 and 16.

Mr. Chamberlain is advised that the information available does not justify further legislation on the use, for treatment of disease, of electrical methods as well as x rays and ultra-violet rays by unqualified practitioners.

The revenue from the sale of alcohol and narcotic drugs in the provinces of India in 1925-26 was 1,930.8 lakhs of rupees.

During 1927 seventeen applicants for service in the Post Office as boy messengers were rejected for flat-foot.

The Ministry of Health has received no report from the West Ham Board of Guardians on the health of the children boarded out by them. These children are regularly inspected.

The Government think it inexpedient to ratify the Convention accepting the prohibition of the use in war of asphyxiating poison or gases until all important Powers have ratified the Protocol, or have signified their intention to do so.

The average daily number of cases under treatment at Haslar Royal Naval Hospital in 1927 was 366, against 381 in 1926 and 538 in 1925. The peace accommodation is 88 officers and 1,059 men; the annual cost in the year ended September last was £105,419.

## Medical News.

A MEETING of the Harveian Society of London will be held at the Paddington Town Hall, W., on Thursday, March 15th, at 8.30 p.m., when Sir William Willcox, K.C.I.E., will deliver the Harveian Lecture on toxicology in its application to medical practice.

A Conference on the Place of the Practising Midwife in Relation to the Protection of Motherhood will be held at the Royal Society of Arts, John Street, Adelphi, on Wednesday, March 7th, from 5 to 7 p.m. The chair will be taken by Sir Francis Champneys, Bt., M.D., chairman of the Central Midwives Board, and the speakers will include Dr. John S. Fairbairn, Dr. J. A. Willett, and Dr. Oxley.

THE Right Hon. J. H. Whitley, M.P., Speaker of the House of Commons, will open the new building of the Leeds Dental School on March 16th at 2.30 p.m. Some particulars of the growth of the school and of the new building were published in our issue of January 14th, p. 72. After the opening ceremony visitors will have an opportunity of inspecting the rooms, and at 4 p.m. honorary degrees will be conferred upon the Speaker and other distinguished persons.

A DISCUSSION on neurases in the tropics will take place at a joint meeting of the Sections of Tropical Diseases, Psychiatry, Neurology, and Bacteriology of the Royal Society of Medicine to be held at 1, Wimpole Street, W.1, on Tuesday, March 13th, at 8.30 p.m.

THE thirteenth Guthrie Lecture before the Physical Society on electrodeless discharge through gases will be given by Sir Joseph Thomson, O.M., F.R.S., on Friday, March 9th, at 5 o'clock, at the Imperial College of Science and Technology, South Kensington. No tickets are required.

THE course of three post-graduate lectures on cancer at the Leeds Medical School on March 7th, April 4th, and May 9th is under the joint auspices of the Yorkshire Council of the British Empire Campaign and the Leeds and West Riding Medico-Chirurgical Society.

THE Fellowship of Medicine announces that Dr. C. M. Wilson will lecture on the chronic abdomen on March 5th, at 5 p.m., at the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1. On March 6th, at 3 p.m., Dr. F. Herniman-Johnson will deliver a lecture, illustrated by radiographs, at the British Institute of Radiology, 32, Welbeck Street, W.1, on x rays as an aid in the diagnosis of abdominal disease, and on March 7th, at 5 p.m., Mr. T. Jefferson Fanlender will give a clinical demonstration at the Golden Square Throat Hospital. The lecture and two demonstrations are free to medical practitioners. Three two weeks' courses begin on March 5th—namely, in gynaecology at the Chelsea Hospital for Women, in diseases of children at the Queen's Royal Eye Hospital. An all-day course will be held at the Brompton Hospital for one week, beginning March 19th. From March 19th to 31st inclusive there will be a course at the Royal National Orthopaedic Hospital, and from March 19th

to 30th a course for the general practitioner at the Hampstead General Hospital daily from 4.30 to 6 p.m. No special courses will be begun subsequently until April 16th, but the Fellowship of Medicine provides a general course of instruction at hospitals, for which comprehensive tickets are issued for varying periods. Further information may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A POST-GRADUATE course in neurology and psychiatry will be held, in English, at Vienna, under the auspices of the American Medical Association of Vienna, from June 1st to July 31st. Further information may be obtained from Dr. E. Spiegel, Falkenstrasse 3, Vienna I.

THE Central Committee on Rheumatism of the International Society of Medical Hydrology has decided to organize clinical conferences on cases of rheumatic disease in hospitals, with the assistance of members of the different national committees. In connexion with the inaugural meeting of the French Committee on Rheumatism in Paris on April 2nd a conference will take place, with the collaboration of French physicians, at La Pitié Hospital and the Salpêtrière. Any medical men desiring to attend this conference can obtain further information from the secretary of the French Committee, Dr. H. Forestier, 10, Rue du Mont Thabor, Paris (8).

THE tenth International medical post-graduate course, with special reference to balneology and balneotherapy, will be held at Carlsbad from September 23rd to 29th, 1928. Clinicians and scientists from the medical faculties of Austria, Bulgaria, Czechoslovakia, Denmark, England, France, Germany, Italy, Norway, Poland, Sweden, Switzerland, and the United States of America will give addresses. England will be represented by Professor Hugh MacLean and Dr. George Graham. An invitation is extended to all medical practitioners. Those who accept will receive a passport visé without charge and a 33 per cent. reduction on all State railways in Czechoslovakia. A programme of entertainments has been arranged. Full information may be had from Dr. Edgar Ganz, secretary of the medical post-graduate course, Carlsbad, Czechoslovakia.

THE Standing Committee appointed by the Board of Trade will hold an inquiry on March 5th and 6th as to whether the following imported goods should bear an indication of origin: surgical, medical, dental, and veterinary instruments and appliances, aseptic hospital furniture of all descriptions, dental supplies of all descriptions other than glassware, and dental furniture of all descriptions. The inquiry will be held at the Board of Trade Offices, Great George Street, S.W.1. Communications should be addressed to the secretary, Mr. E. W. Reardon, at that address.

THE second Hispano-Portuguese Congress of Urology will be held at Madrid from May 10th to 16th. Further information can be obtained from the general secretary, Dr. T. S. Corlisa, Calle de Alcalá 95, Madrid.

THE National Institute of Industrial Psychology, which was founded seven years ago for the application of the human sciences to the everyday needs of industry, has received an anonymous gift of £4,000 towards the cost of new premises.

WE have received the first issue, dated January 15th, 1928, of a new monthly journal on anaesthetics entitled *Narkose und Anaesthetica*, and published at Berlin under the editorship of Dr. H. Franken of the Freiburg University Women's Clinic, assisted by Drs. H. Eppinger and O. Pankow of Freiburg, E. Rehn of Bonn, and P. Trendelenburg of Berlin. The issue contains an original article by Dr. H. Lindemann of Düsseldorf on new methods for producing anaesthesia of the jaws and face, a review by Dr. Hans Killian of Düsseldorf on the results of rectal anaesthesia by avertin, and abstracts from current literature.

It is announced in the January issue of the *British Journal of Anaesthesia* that a prize of £50 is offered in commemoration of the late Dr. Sidney Rawson Wilson for the best research on inhalation anaesthesia between now and December 1st. In sending the essay a *nom de plume* is to be used; further information may be obtained from the editor of that journal "Ainsdale," Palatine Road, Withington, Manchester.

THE subject of tetra-ethyl lead as an addition to motor spirit, which is referred to at pages 363 and 366 of our present issue, was raised in the House of Lords on Wednesday by Lord Buckmaster, who moved that the Government should immediately set up a committee to advise as to the public danger that might arise from this cause. Lord Salisbury, in replying for the Government, said that an interdepartmental committee would be appointed forthwith, containing representatives of the Ministry of Health, the Home Office, and the Medical Research Council. On this undertaking Lord Buckmaster withdrew his motion, after insisting that eminent chemists ought to be included in the membership of the committee.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **British Medical Journal** must communicate with the **Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1**, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the **Financial Secretary and Business Manager**.

The **TELEPHONE NUMBERS** of the **British Medical Association** and the **British Medical Journal** are **MUSEUM 3861, 3862, 3863, and 3864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **British Medical Journal**, *Aitiology Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Mediscera Westcent, London.*

The address of the **Irish Office** of the **British Medical Association** is 16, South Frederick Street, Dublin (telegrams: *Ilacillus, Dublin*; telephone: 4737 Dublin), and of the **Scottish Office**, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

### QUERIES AND ANSWERS.

#### PHYSIOLOGY OF DEFAECATION.

**DR. A. C. JORDAN** (London, W.) writes: In reply to numerous inquiries regarding the **v.c. foot-rest** referred to in my letter of February 18th (p. 292), the address of the makers is the **F.A.F.R. Company, 36, North Gate, Newark, Notts.**

#### FIREMEN'S CRAMP.

**DR. F. G. GARDNER** (Oxford) writes: I believe the view now held is that cramp occurring in firemen and others working in great heat is due to a deficiency of sodium chloride in the system, as the result of excessive sweating. If this is so, prevention should be a simple matter. A large quantity of cold water quickly swallowed will induce "cramp" in anyone—as many of us know from experience. A safer drink, and one more satisfying to the thirsty, is oatmeal water. A contributory cause of cramp is exposure of the abdomen, either at work or at rest; the rapid evaporation of the sweat causes "absorption of heat," and so the blood is "chilled" over a large and somewhat superficial area. Those who "go down to the sea in ships"—naval engineers and others—have opportunities of testing the theories I allude to in a very simple manner, and their experiences would be useful and interesting.

#### INCOME TAX.

##### Motor Car Renewals.

"H. C. M." bought an "H" saloon (11.4 h.p.) in 1922 for £750 and has now replaced that car by a "W" saloon (16 h.p.) for £495-£140=£355. He asks what claim he can make, "taking into consideration the increased horse-power." He has not made any annual claim for wear and tear.

\* \* Nominal horse-power is only one consideration among several indicating the capital value of a car, and seeing that the list price of the second car is £155 below that of the former car, we are of opinion that "H. C. M." may fairly claim the whole of the out-of-pocket expense—£355—as an expense of renewal.

#### Sale of Practice.

"R. A. M. C." was in partnership from October, 1922, to September 30th, 1926, and on his own account to September 30th, 1927, as from which date he sold his practice and has been unemployed. He has received applications for payment of tax "from the inspector's office, £34 odd, and from the collector's, £6 plus £27."

\* \* His liability will be represented by the tax applicable to (1) a half-share of the practice profits to September 30th, 1926; (2) the whole of the profits (as calculated on the usual average) for the half-year to March 31st (or April 5th), 1927; and (3) the half-year to September 30th, 1927, based on half the amount of the profits of the year to September 30th, 1926, or to whatever may have been the usual date taken for income tax purposes. If the whole of the cash received for practice debts is brought into the computation of the practice profits after the dissolution of partnership at September 30th, 1926, then the £100 received since September 30th, 1927, should be ignored. "R. A. M. C." will probably find that the applications by the inspector and collector refer to the same amounts of tax, and should not be regarded as independent.

## LETTERS, NOTES, ETC.

### RAPID FIRST LABOUR.

**SURGEON COMMANDER G. V. HOBBS, R.N.**, writes: The account of two cases of painless natural labour (*JOURNAL*, January 21st, p. 120, and 28th, p. 164) prompt me to mention the following case I attended some years ago, which I think must be equally rare. I was called one night to see a young married woman said to be suffering from acute abdominal pain. It was obvious she was in labour, and after examination I expressed the opinion that the child would not be born for some hours; I then found that she was unaware of her condition. I was also surprised when a perfectly healthy child of 7 lb. was born only two hours later, three and a half hours after the first pain. It appeared that seven months previously she attended her own doctor for the amenorrhoea, who, finding she was suffering from anaemia, gave him as a probable cause and prescribed for it. The patient thought this treatment beneficial, causing her to put on weight. There was no evidence of quickening, and she felt perfectly fit during the whole of her pregnancy, playing tennis, and even going for a twelve-mile walk with her husband the day before the child was born. The points of interest in the case are: (1) The short period of labour for a primipara—namely, three and a half hours. (2) The lack of distress of the patient: she was most anxious to get up the next day, as she felt so well. (3) The absence of any reason for concealment of her condition. (4) The fact that she was staying at the time with her mother-in-law, who evidently noticed nothing. (5) This case also illustrates the advantage of a pregnant woman leading a normal life, instead of pudoring to false modesty by staying indoors and taking very little exercise, a proceeding all too common at the present day.

**DR. M. M. RUSSELL** (Sutton) writes: At the risk of increasing incredulity I am prompted by recent letters in the *JOURNAL* to mention a case which I attended while on extern duty at the *Romunda Hospital, Dublin*, in 1915. I was called to see a stalwart young primipara in labour who, after I arrived, had three uterine contractions without any discomfort, with the head on the perineum. She then declared that the "baby was coming," and on the next contraction the head was born with the membranes intact, and was then completely withdrawn within the vulva again. I ruptured the membranes and the child was born forthwith. It was . . . here was no perineal laceration.

### A SCARLET RED DRY DRESSING.

**D . . .** Isle of Man) writes: I should like to mention of scarlet red incorporated into . . . out of indolent ulcers. It is prepared as follows: A solution is made of 20 grains of a Biebrich red (chemically . . . acid) in a . . . The lint is immersed in this solution for two days, during which period it should be occasionally compressed, so that the solution properly permeate the material. Without wringing or may thoroughly permeate the material. Without wringing or the use of artificial heat it is allowed to dry, and is then ironed at a low temperature. These details, even if only roughly followed, will furnish a satisfactory dressing, which should be applied at least twice a day, the piece of material employed being cut exactly to the size and shape of the ulcer.

### HAEMOPTYSIS IN INFANTS.

**DR. C. J. BATTLE** (Klerksdorp, Transvaal) records the case of a male European infant, aged about 3 months, who was found one morning with a little red blood running out of his mouth. He then commenced coughing and coughed up a bluish clot. Later he again coughed, went blue in the face, and coughed up blood he again coughed. The same night he passed black stools. The mixed with slime. The face was rather leaden. In the left lung child looked ill and the face was rather leaden. In the left lung there were many crepitations, chiefly in the upper lobe; there was no pyrexia and the heart was normal. In the afternoon fresh blood and a small clot or two were found in his mouth. It was stated that these had been coughed up; there had been no epistaxis, and there appeared to be nothing in the mouth or throat to account for the blood. The infant was given an injection of about 2 c.cm. haemostatic serum, which was repeated next day; the calcium was administered by the mouth. Two days later the temperature was 100° F. in the rectum, and on the fourth day it was normal again. There was no more haemorrhage after the first injection. On the second day of illness there were signs of bronchial catarrh in both lungs, and this lasted for a week or two. Since then, he has been well. Dr. Battle adds: The due to errors of diet, he has been well. Dr. Battle adds: The interest of the case appears to me to lie in the fact that haemorrhage from the lungs appearing at the mouth in infants is exceedingly rare, and, according to Porter and Carter of San Francisco in their book *Management of the Sick Infant*, is practically unknown.

### VACANCIES.

**NOTIFICATIONS** of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 46, 47, and 50 of our advertisements, columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 48 and 49. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 75.

## An Address ON CHRONIC INTESTINAL TOXAEMIA IN CHILDREN.

DELIVERED BEFORE THE HAMPSHIRE MEDICAL SOCIETY,  
JANUARY 19TH, 1928,

BY  
REGINALD MILLER, M.D., F.R.C.P.,  
PHYSICIAN, PADDINGTON GREEN CHILDREN'S HOSPITAL; SENIOR PHYSICIAN  
TO OUT-PATIENTS, ST. MARY'S HOSPITAL, LONDON.

THE chief object of this address is to direct attention to the type of child who is persistently out of health owing to chronic intestinal toxæmia. I shall deal, first, with the signs and symptoms by which it may be recognized; secondly, with the various forms of intestinal derangement responsible for it, some of which are special to childhood; and finally, with the principles of its treatment. But I have also a subsidiary purpose in view, which is to emphasize the fact that in many of these children the most conspicuous symptoms are those pointing to disorder of the nervous system, so that there is a danger that the causative physical condition may be overlooked and the case regarded as a purely psychological problem. In these days, when the psychology of the nursery is so much under discussion, this danger is, at least in my opinion, by no means remote.

### RECOGNITION OF THE "INTESTINAL CHILD."

The "intestinal child"—as, for lack of a better term, we may call the type produced by chronic intestinal toxæmia of all sorts—is often easily recognizable at sight, but it is seldom brought to see the doctor for any one very definite symptom. Occasionally it is brought for irregularity of the bowels, sleeplessness, persistent nocturnal rise of temperature, or bouts of feverish biliousness. Much more often it is brought that the parents may learn whether it is ill or not; and it is noticeable how often both parents accompany the child, so nonplussed are they about the whole business. "Why does it look like this? Why does it behave as it does? Surely there must be something wrong with the child." These are the things they say, the implication being, of course, that to such parents no child who is not placid but brilliant, and as least as beautiful as it is good, should have been vouchsafed. And indeed it must be confessed that the child brings its parents little satisfaction and no credit, for its appearance suggests exhaustion from a spell of debauchery, and its deportment is frankly impossible. In these days, when the sins of the children are visited upon the fathers unto the third and fourth generation, the parents of the intestinal child are little to be envied.

The symptoms of the child are perhaps best summarized under the headings of unhealthiness and unhappiness. In appearance (often so characteristic) it is thin and sometimes undersized; its complexion is pale, sallow, and muddy; its eyes, especially towards evening, are darkly ringed and the lower lids are baggy; its tongue is coated, its breath foul, and its odour often strong. Especially is it noticeable that the child looks completely tired out; it may feel and behave as though languid and exhausted, but more often it is feverishly active, chiefly in wrongdoing. Its appetite is bad, except perhaps for breakfast, after a purge, at a party, or on holidays. So bad may it be that meals are often a burden and sometimes a horror to the family. Its sleep is usually poor: awake late at night, disturbed by frightening dreams, it is agog to be up and doing at dawn. Sweating is common during the night, and a persistent low fever may be discovered. This not unnaturally adds to the parents' alarm, and often the doctor, who has hitherto regarded the whole business as due to bad management and spoiling, becomes obsessed with the idea of the presence of tuberculous mesenteric glands: in this he will seldom be correct. Perversions of appetite,

such as dirt-eating, gnawing of bedclothes, and others, are not uncommon.

The nervous symptoms are often more conspicuous than those of physical ill health, and I have already mentioned some of them. Taken as a whole the child is chiefly unhappy, and its misery spreads to those round it. It is unreasonable, ill humoured, cantankerous, self-centred, emotional, negative—everything, in short, that can make a child unpleasant. In milder cases it is shy, frightened, occasionally spiteful, and on the whole disappointing; but more often it is actively and aggressively unpleasant. Much has been made of the negativism of nervous children, but it is the inevitable expression of morose irritation and exhaustion. How also can a child show this? It cannot go home and bully its wife and family; so it shows its ill humour in refusing to do the ordinary things expected of it—the child's method of bullying.

The intestinal child is often in character singularly unlike its brothers and sisters. The parents, thinking on psychological lines, are reminded of the nervous taints and peculiarities in each other's relations, but surely in such circumstances a physical cause for the child's ill health should suggest itself.

In many cases the symptoms are altogether milder and less harassing, and here we see the difference between the normal and the neurotic temperament. The placid child, poisoned from the intestine, becomes sleepy, tired, apathetic, and protects its incapacity by withdrawing its interest from its surroundings. The neurotic child, on the other hand, becomes in its fatigue more restless, and so enters into the vicious circle so well demonstrated by adults who have command of their own course.

Thus far, then, we have the picture of our too-familiar friend the "nervous child." How are we to distinguish the group which originates in intestinal toxæmia? It is true that in most cases the very appearance of the child's face should suggest the presence of a toxæmia quite decisively; but there are other signs which point clearly to the intestinal tract, and of these I place reliance chiefly on the following: (a) enlarged abdomen; (b) the occasional or persistent occurrence of abnormal stools; (c) the presence of gross indigestion as shown by microscopical or chemical examination of the faeces; (d) the presence of much indican in the urine.

Enlargement of the abdomen is frequently overlooked by parents and doctor, and if recognized it is often misinterpreted. A child's abdomen ought not to swell visibly from time to time, or to diminish visibly after an action of the bowels. I always view with suspicion an abdomen of which the mother says it is the child's "best part." Enlargement of the abdomen must, then, be looked for, and if found must be explained. In intestinal toxæmia the distension is chiefly due to flatulence, the result of stasis, indigestion, malabsorption, and decomposition. The stools may be abnormal in various ways. Usually constipation is present, but this alone is not enough to give rise to toxæmia. The stools are frequently undigested or foul, and if careful notice is taken it will be found that at such times the child is worse: its complexion, appetite, temperature, and behaviour are all affected. The various forms of indigestion and malabsorption of food, as found by microscopical examination of the stools, I will deal with later.

But, it may be said, granted that there is an association between disorders of the nervous system and intestinal toxæmia, who is to say which is the cause and which the effect? Now I readily admit that just as there are "nervous children" without intestinal symptoms, so there is nothing to prevent a nervous child from developing intestinal toxæmia; further, that it is clear that in a neuropathic child nervous symptoms would be produced by a smaller degree of such toxæmia than in a more stable subject. Yet to distinguish between such causes and effects in individual cases is surely the customary task of the physician, and I here need only produce evidence that intestinal toxæmia is capable of producing the psychological picture of the "nervous child."

On this point I would say, first, that from the early days of babyhood intestinal derangement, apart from

pain, has a great effect on the nervous system: tetany and convulsions are but extreme examples of this. For a baby's misbehaviour there is still more merit in a dose of castor oil than in the most modern psychology of the nursery. In matters scientific the infant remains sadly out of date, and even the small child conservative. Secondly, as showing the possible production of nervous symptoms by intestinal toxæmia, I would cite as the clearest proof the child with coeliac disease. Here we have all the eccentricities of the "nervous child" in *excræsis*—the negativism, the introspection, the so-called "anorexia nervosa," and the rest of them. While psychological treatment alone is here a complete failure, correct dieting brings about gradually such a change for the better that the child becomes easy, well behaved, and lovable. Yet with an extra dose of fat, bringing back abdominal distension and foul stools, there reappear the irritability, the loss of appetite, and the unhappiness. I have seen this so often that I cannot doubt the sequence of events. Further evidence to the same point might be given. I could quote the experience of adults with intestinal toxæmia, the effect of Plombières treatment, and the alteration in the disposition of the "intestinal child" when properly treated; all these show that a toxæmia of intestinal origin can have a profound effect on the nervous system.

I will therefore conclude with two submissions. First, that any child who is brought to us for marked nervous symptoms and peculiarities should be examined with great care for some possible physical cause, particularly one originating in the intestine; remembering that the nervous symptoms are often so conspicuous that they are likely to mask the less evident intestinal symptoms. Secondly, I would urge that where intestinal toxæmia can be proved, a generous allowance should be made for the child's misdoings. I have seen such alterations in disposition in these cases that I am convinced that allowances should be made for these children on the ground that they are really ill children. I would even go further than this, and suggest that a like measure of charity be extended to the mother herself. For her to see her child looking often enough like a dissipated drug addict and behaving like a fiend is more than likely to make her morbidly anxious and unwise. After all, if our mothers may not be "unwise" with us, who may?

#### FORMS OF INTESTINAL DISORDER PRODUCING THE INTESTINAL CHILD.

Let me first exclude two conditions which should not be classed as causes of intestinal toxæmia—namely, simple constipation and abdominal tuberculosis.

Simple constipation does not, in my opinion, give rise to toxæmia. In a child, if it produces any symptoms, they are those of abdominal distension; pain, particularly after food (of which constipation is the commonest cause in a child); and perhaps some lack of appetite and disturbed sleep. Where toxæmia develops I class the case as one of toxic constipation or of the other types to be considered in a moment.

Abdominal tuberculosis is often diagnosed in those cases because there are chronic ill health, abdominal enlargement, and nocturnal fever with sweating. As a matter of fact, in the richer classes it is by far the least common cause of this triad of symptoms. Yet it is diagnosed because the doctor does not appreciate the alternative possibilities, and perhaps has not examined the stools. A child cannot be ill for two or three years from abdominal tuberculosis and yet show no abnormal signs in the abdomen. Tuberculous glands are the commonest lesion diagnosed, but there is no reason at all why their presence should be accompanied by foul and undigested stools. Some confirmatory sign should be elicited before such a diagnosis is made.

I turn now to the various digestive disorders which may give rise to intestinal toxæmia in children.

#### Coeliac Disease.

I put this first because it is both common and clearly recognized. I have not here in mind the classical form of the disorder, with its large, pale, offensive, unformed

stools containing a great excess of fat, chiefly in the form of fatty acids. Rather I refer to the milder type which I have elsewhere described as the non-diarrhoeic type, in which the stools are large, formed, coloured, and contain their excess of fat chiefly in the form of soaps. This type gives rise to abdominal distension and considerable toxæmia, and can, of course, be recognized by a careful analysis of the stools on ordinary and on fat-free diets. There are, however, a few points which are of aid in reaching a diagnosis clinically. Growth in height is retarded more constantly and more seriously in this group than in any of the other forms of intestinal toxæmia. Flattening or wasting of the buttocks is a suggestive sign.<sup>2</sup> Lastly, coeliac children are very seldom constipated, and in this they differ from most other cases of intestinal toxæmia. On the contrary, the bowels act very regularly, and however little the child may eat one day it will not fail to pass a good-sized stool the next. How often this leads to the erroneous conclusion that there is nothing wrong with the intestine! Yet it is a noteworthy point in favour of malabsorption of fat.

I must not forbear to mention that H. C. Cameron, who has written so instructively and delightfully on the "nervous child," has repeatedly laid stress on its inability in many cases to take fat well. In doing so he has had, I think, the tendency to acetonaemia chiefly in mind. The intestinal child is not the type which is prone to true primary acetonaemia (cyclical vomiting), although it may have feverish bilious attacks with secondary acetonaemia. In the coeliac cases the child cannot absorb fat properly, and to give it induces toxæmia and perhaps a low persistent fever. In other types of intestinal toxæmia cooked fats (of roast meat, sausages, rich gravies, etc.) will upset, just as they will similar cases in adults.

#### Starch Indigestion.

In spite of the amount of attention paid to it in the textbooks I have not found this to be a common cause of intestinal toxæmia. It can be easily recognized in a microscopical examination of the stools, and may be suspected where a child passes rather loose acid stools, pitted or honeycombed from the evolution of gas. Such indigestion sets up a secondary colitis. These cases seem chiefly to arise from overfeeding with starch, but there seems little doubt that rarely there is a great intolerance of starch.

#### Nut Indigestion.

In the last three or four years I have met with a dozen or more cases of chronic indigestion in which the stools were full of undigested nut cells. These are easily recognizable as being the only vegetable cells which contain oil. The amount of these has been in some instances sufficient to make the stool large and fatty. I am not satisfied that I have always been able to explain the presence of this, and suspect that crushed nut is being used in some foods which I have not yet traced.

#### Lamblia.

Infection by this flagellate protozoon is now very common amongst the children of the hospital class in this country. I have published<sup>3</sup> a study of the effects of it on them. It produces an enterocolitis with some distension of the abdomen and loss of weight. It is, however, more characterized by intractable diarrhoea than by an obscure toxæmia. The stools show all sorts of undigested food, mucus, but no blood. The flagellate is easily seen under the microscope during the diarrhoeic periods.

#### Toxic Constipation.

Lastly, there is the group of unclassifiable forms of intestinal indigestion similar to the usual adult type. Their origin is as difficult to dogmatize on in children as in adults. Personally, I believe that they arise in various ways. Some are the sequel to acute enterocolitis—for example, dysentery. Others are possibly the result of infection of the intestine from above—for example, infected tonsils or antra. By far the most common type,

however, is that which follows prolonged constipation: a harmless or simple constipation turns into a toxic constipation. How is this transformation brought about? I believe that abnormal infective agents have very little to do with it in ordinary cases, but that the sequence of events is increasing constipation causing faecal decomposition, which in its turn produces irritation and catarrh of the colon. In this the chemical irritants of decomposition are often aided by the use of improper purgatives and an unsuitable diet of "roughage." In my view it is the supervention of this mild colitis which permits the absorption of toxins from the bowel. A great function of the colon is to refuse to absorb the poisons which are ever present within it—at least in quantities greater than can be dealt with by the liver; it is not, therefore, unreasonable to assume that where the wall of the colon is abnormal its impermeability is impaired.

With the onset of the colitis there is not only toxæmia, but pain or discomfort in the hyperæsthetic colon may develop. Spasm of the colon (spastic constipation) is rare in childhood.

In such cases of stasis the stool is usually alkaline in reaction, and rather foul and greasy from the presence of a little mucus. Microscopically the food residues are found to be finely divided; the muscle fibres small, pale, rounded, with their striation largely lost. Although there is no excess of fat in the stool, many bundles of coarse fatty crystals can be found by the microscope. Oxalate crystals are also numerous. The benzidine test for occult blood is usually positive. The bacteria may be normal, but frequently there is a proportionate excess of streptococci. Other and more abnormal organisms are sometimes present, but I have seldom been able to trace any significance to them. Although the amount of mucus seen in the stool in ordinary circumstances is scanty, on washing out the bowel there is usually plenty, both old and recent. The urine contains a large amount of indican and many oxalate crystals.

Two conditions sometimes associated with toxic constipation require mention: parasites and appendicitis. This is the type of case in which threadworm infection is common. Except for local symptoms I do not believe its presence makes any difference. The so-called symptoms of threadworms are, for the most part, those of toxic constipation and colitis.

Recurrent appendicitis is common enough in children. Whether there is in them a condition similar to the so-called "chronic appendix" of adults is questionable. I will only say that I regard right-sided abdominal pain and tenderness as much more indicative of appendicular disease in a child than in an adult. My reason for saying this is, that although in adult cases there are many who still complain of the same pain after their appendix has been removed, it is very rare, in my experience, to meet such in childhood. With that I will leave it.

#### PRINCIPLES OF TREATMENT.

The treatment of intestinal toxæmia in children is apt to be long, and much patience and attention to detail are necessary to obtain good results. Here I can only very briefly enunciate the principles which should guide the treatment.

#### Rest.

Many of these children, when first seen, are tired and ill enough to benefit from a month's rest in bed. Where this is unnecessary, enough rest to ensure freedom from exhaustion must be maintained. Where restlessness is troublesome sedatives should be ordered; bromide is a sheet-anchor here. In older children adalin is very useful to promote sleep.

#### Diet.

Where the exact fault in digestion is known the alterations in the diet are clearly indicated. Dealing with the group of cases termed above "toxic constipation" the diet should be suitable for the associated colitis. This is quite different from that used for simple constipation, for the aim here is to give a diet which will leave a small smooth residue, and all sorts of "roughage" are

out of place. Fresh fruit, except orange juice and squashed ripe banana, should be forbidden, and cooked fruit given only sparingly and without pips or skins. The vegetables allowed should be only such as can be put through a sieve. Cooked fats of roast and fried food and rich gravies often disagree. On this diet, although the constipation may be increased, discomfort and distension are lessened, and a chance is given to the colitis to subside.

#### Aperients.

Much depends upon the selection of an aperient which, when given regularly, is efficient yet harmless. The aim should be to produce a stool which is soft but formed, avoiding either a constipated or a watery action. Liquid stools are far more toxic than are formed ones.

It is rather characteristic of the cases of toxic constipation that they are ordered doses of calomel once or twice a week. These, although they do temporary good, are liable to set up or increase colitis. Even for emergencies castor oil is safer.

Paraffin is, perhaps, the drug in most common use. Where quite small doses are effective there is small objection to its use; in large doses it is quite unsuccessful. Stools full of paraffin ferment readily, and a microscopical examination of them shows how great is the interference with protein digestion. On large doses children remain distended and toxic, and their tongues coated. An emulsion of paraffin and phenolphthalein has much more "cleansing" power, and, where it works efficiently in small doses, makes a good aperient for some of these cases. Cocoids of phenolphthalein make a very palatable aperient for small children, and magnesia may be sufficient for others. All preparations of senna and cascara are best avoided, if possible, for persistent use.

Where the child is old enough to swallow a tablet we have the group of bile preparations of which the proprietary preparation taxol is a pattern. These, in my experience, are extraordinarily successful, and on the whole a great advance on any of the other aperients for daily use. They produce no griping, the liver action is stimulated, the motions, with a properly adjusted dose, are soft but formed. In young children I have often prescribed taxol ground up in jam.

#### Intestinal Lavage.

Intestinal wash-outs are very useful in really severe cases, even though they may mean that the child will require more rest than would otherwise be necessary. They should be given about twice a week. The fluid used may consist of equal parts of Plombières water and ordinary water, or of a solution of 2 drachms of salt and 1 drachm of sodium bicarbonate to a pint of water; 1 to 1½ pints should be run into the bowel from a funnel, through a soft rubber catheter, and evacuated after being held in the bowel for a minute or two. Where proper Plombières treatment is available it is more efficient, but in children the wash-outs given at home are often quite successful. After six or eight treatments at three-day intervals it is usually possible to lengthen the intervals between the treatments. They should not be continued too long nor left off too abruptly.

#### Massage.

Some massage should be given, if it causes no pain, along the colon when cleared out by the wash-out. An overloaded bowel should not, I think, be subjected to massage; the bowel should first be emptied. Many cases show secondary dilatation of the stomach, and light massage for this is useful. General massage is rarely advisable, and should certainly not be ordered until all fatigue has passed off.

#### Later Measures.

As the child improves appetite and sleep return, and progress then is usually fairly assured. Additions may now be made to the diet and to the amount of exercise allowed. Change of air, and artificial or other sunlight, are of value.

# Hunterian Oration ON SCIATICA: ITS VARIETIES AND TREATMENT.

DELIVERED BEFORE THE HUNTERIAN SOCIETY ON  
FEBRUARY 27TH

BY

ANTHONY FEILING, M.D., F.R.C.P.,

PHYSICIAN AND DEAN OF THE MEDICAL SCHOOL, ST. GEORGE'S HOSPITAL;  
PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA  
VALE, AND TO THE ROYAL NATIONAL ORTHOPAEDIC HOSPITAL.

WITH the recent celebrations of Hunter's bicentenary fresh in all our minds it is quite unnecessary for me to insist on the debt which the medicine and surgery of to-day owe to him and his tradition.

That Hunter himself was fully alive to the interests afforded by the subject of my address may easily be seen from the following quotation from one of his lectures:<sup>1</sup>

"A gentleman complained of a pain in the hip, running down the outside of the leg and foot. Supposing it rheumatism I gave him James's powder, Dover's powder, and volatile tincture of guaiacum, but with no good effect. A liniment of opium to the leg and foot gave some relief. He at last perceived a tumour by the os ischii, just at the posterior edge of the gluteus maximus. This tumour increased and the person died. The tumour was found to fill a part of the pelvis, and had made its external appearance at the foramen magnum ischii, being filled with coagulated blood; but the pain in the limb seemed to have been produced by its pressing on a great branch of the nerve, but chiefly perhaps from the great ischiatic nerve being stretched very tight over the upper surface of the tumour. Here that happened which may often be observed: that is, the impression made on the trunk of the nerve gave a sensation as if it had been on the extremities of the nerve."

I make no apology for the choice of my subject for this Oration, trite though it may at first sight appear. The aggregate of suffering and of disability in the shape of work and wages lost through this common disorder is sufficient excuse for any attempt to clarify its causes or rationalize its treatment.

It is unfortunate that the term "sciatica" is one of those which have been accepted by the public and used by them to designate almost any kind of pain in the region of the lumbar spine, buttock, hip, and leg. Like certain medical terms—"rheumatism" or "anaemia," for example—it covers a multitude of sins; it sounds sufficiently scientific to lull the patient into a belief that the real nature of his symptoms is known, even allowing him to seek various forms of treatment—hydropathic, electrical, and so on—entirely on his own responsibility.

We should think of sciatica as merely signifying sciatic pain—that is, pain in the distribution of the sciatic nerve—without allowing it to connote any particular pathogenesis. This simple anatomical reminder will at once prevent us from lightly labelling as sciatica any case where the pain affects, for example, the front of the leg or the groin. It is hardly possible now to abandon the use of the term "sciatica," which is particularly useful in denoting one common variety of the disorder to which further reference will be made.

## TWO TYPES OF SCIATICA.

For purposes of convenience we may speak of (1) a secondary or symptomatic sciatica, and (2) a primary or essential sciatica. By secondary I mean a sciatica due to some gross pressure lesion; by primary or essential I mean that large group of cases where no gross pressure lesion can be demonstrated, whose exact etiology is a matter of doubt and dispute. Strictly speaking, it is, of course, inadmissible to call such cases primary or essential—there is probably no such condition—but the term is useful and difficult to replace.

May I remind you very briefly of a few important anatomical points? The great sciatic nerve is formed in the sacral plexus from the anterior primary divisions of the fifth lumbar and the first and second sacral nerves; smaller branches join it from the fourth lumbar and the third sacral nerves. From its position on the posterior pelvic wall where the plexus is formed the great sciatic nerve passes into the buttock through the great sacro-

sciatic foramen between the pyriformis and superior gemellus muscles. It passes down into the thigh in the hollow between the great trochanter of the femur and the tuberosity of the ischium.

The part played by the fifth lumbar nerve in the production of symptoms is a point of considerable clinical importance; anatomically this may be in part explained by the longer and more oblique course it has to take to reach the plexus, as well as by other considerations to which I shall have to refer later.

Before proceeding to consider what I have called the primary sciaticas something must be said about the secondary or symptomatic forms.

## SECONDARY SCIATICAS.

These may, of course, be due to a large variety of different lesions. Tumours of the rectum or of the pelvic organs, primary or secondary growths of the bones of the pelvis or of the vertebral column, disease of the hip-joint, the sacro-iliac joint, or the joints of the lumbar vertebrae; various affections of the actual nerve roots of the cauda equina within the theca or outside it, such as syphilitic inflammation or pressure by tumours; the effects of old injuries and disease of the spinal cord such as tabes dorsalis. All of these are possible causes of sciatic pain. In practice, however, the great majority of such possible causes are easily ruled out by a careful physical examination, which must in all cases include the vertebral column and hip-joint, the abdomen, including rectal and sometimes pelvic examination, and the nervous system.

In my experience it is relatively uncommon to find gross pressure lesions such as that produced by pelvic tumours, growths in the rectum, or abdominal disease overlooked. On the other hand, osteo-arthritis of the hip-joint is repeatedly overlooked as a cause of so-called sciatica, and much valuable time often wasted thereby on methods of treatment which can serve no useful purpose. Careful movements of the hip-joint by the observer should not produce pain in the case of true sciatica, nor is there any real limitation of the range of the movements of the joint. The importance of radiography is so obvious as hardly to call for mention.

I do not intend to weary you with a long discussion on the differential diagnosis of all the conditions which may produce a secondary sciatica, but it may, however, be of some value to remind you that the presence of any of the following signs or symptoms should at once arouse suspicion and seriously invalidate the diagnosis of a primary sciatica.

1. The distribution of the pain in any of the following areas: (a) the anterior aspect of the thigh; (b) the perineum, groin, or genital organs; (c) the abdomen or abdominal wall.
2. A motor paralysis of the leg or thigh or even a dropped foot.
3. Loss of the knee-jerk.
4. Any marked muscular atrophy.
5. The presence of the reaction of degeneration in any of the muscles showing slight wasting.
6. Any severe vasomotor disorders, and, of course, any such signs as oedema or trophic ulcerations.
7. Any interference with the nervous control of micturition, defaecation, or the sexual functions.
8. Lordosis or a gross deficiency in the movements of the spinal column.
9. Finally, the history of an operation for malignant disease should immediately raise doubts as to the innocency of any sciatic pains.

It is sometimes stated that a bilateral sciatica is always the result of some gross lesion—that is, a secondary sciatica. Certainly bilateral sciatic pains should always be regarded with grave suspicion, but I have satisfied myself in more than one case that it is possible for an essential or primary sciatica to affect both sides, as well as for a true perineuritis to affect both sciatic nerves.

## PRIMARY SCIATICAS.

We must now turn to consider the primary or essential forms of sciatica. Here it is useful to divide the cases into two groups: (1) those where the symptoms suggest that there is a neuritis of the trunk of the sciatic nerve itself—a true sciatic neuritis; and (2) those where there is no direct evidence of such a neuritis, but where there seems reason to believe that the seat of the trouble lies higher up in the region of the lumbosacral vertebrae. We

can if we choose call this latter group "sciatic neuralgia," but in my opinion little is gained in this further subdivision in nomenclature.

#### *Neuritis of the Sciatic Nerve.*

There can be, I think, no doubt that a true neuritis of the sciatic nerve does exist. It is an interstitial neuritis, or perhaps rather a perineuritis, not in any sense comparable to the degenerative lesions of the nerves which are found in the cases of multiplo neuritis or toxic polyneuritis due to such poisons as alcohol or arsenic. The great majority of cases do not afford us an opportunity of verifying by sight the exact nature of the lesion, but occasionally in cases of very long standing where the nerve has been exposed by open operation cicatrization of the nerve sheath with adhesions to surrounding structures has been demonstrated.

The precise etiology of these cases is generally uncertain. Like other forms of fibrositis, neuro-fibrositis, or neuritis it is now the custom to attribute them to some focus of infection in the body, and it is certainly good practice to institute a vigorous search for any such foci, and if they be found to remove them, if possible. Personally, however, I must confess to little success in this respect, and I doubt if I can recall a single example out of the many cases of sciatica I have seen where the finding of a septic focus, followed by its appropriate treatment, seems to have affected to any appreciable extent the course of the disease. Experience teaches that this form of neuritis occurs in diabetic subjects with a greater frequency than can be explained by mere coincidence; this possibility, therefore, must always be carefully borne in mind.

There are certain features which, I venture to submit, are of considerable value in the diagnosis of this particular form of sciatica. I have already mentioned certain diagnostic criteria which are of the greatest importance in establishing the presence of a gross pressure or secondary form of sciatica as distinguished from the form we are now considering. In the ordinary sciatic neuritis, as indeed in the other variety of primary sciatica which I shall describe presently, the sensory functions of the nerve are affected not merely out of proportion to the motor functions, but practically to their exclusion. A very different picture is generally presented by gross pressure lesions or by traumatic lesions of the nerve trunk. In these latter it is true that sensory symptoms may occur first, but they are soon followed by symptoms on the motor side, muscular weakness, dropped foot, gross muscular wasting, and, finally, even by trophic lesions. In the ordinary form of sciatic neuritis it is quite exceptional to find motor weakness of the limb. Some muscular wasting, it is true, may be found, but except in cases of unusual severity or very long standing it is generally slight in degree and more or less global in character—that is, affecting all the muscles of the limb equally, resembling, in fact, that wasting of the muscles associated with joint disease.

Little help in exact diagnosis is afforded by the well-known test of extending the leg at the knee with the thigh flexed on the abdomen. This manoeuvre will cause pain not only in a true sciatic neuritis, but in numerous other cases as well where the nerve or its roots are affected either by pressure or by inflammation. The simplest test for the presence of a real neuritis of the nerve trunk itself is tenderness on direct pressure. The points where this tenderness is most easily elicited are (1) over the sacro-sciatic notch, and (2) where the nerve enters the thigh midway between the tuberosity of the ischium and the great trochanter. In some cases also extreme tenderness may be found in the popliteal space and over the external popliteal division as this winds round the head of the fibula. Mere discomfort on pressure in these situations is insufficient to warrant the assumption of a real neuritis, which, if present, reacts to such a stimulus by a sensation of pain which is clearly acute.

Another almost invariable sign of a real neuritis is the disappearance of the ankle or Achilles jerk. Its absence, together with an exaggeration of the knee-jerk, is extremely common, and this combination constitutes quite a typical picture of the state of the deep reflexes in the

affected limb. It is remarkable with what rapidity the ankle-jerk may be lost; moreover, it is well to remember that it may never return, its perpetual absence being as it were a scar of the old disease which, many years after perhaps, may complicate the diagnosis of a new train of symptoms in the same patient.

#### *Sciatic Neuralgia.*

I pass on now to consider what is in my own view perhaps the most common form of sciatica. You will, I feel sure, all agree that even when the cases due to gross pressure lesions—that is, the secondary sciaticas—have been weeded out, and when the cases of definite neuritis of the nerve have also been excluded, there yet remains a very considerable moiety of uncertain nature. In this group the pains may be just as severe, just as persistent, and just as genuinely sciatic in distribution as in the forms I have already described. There may be in such cases practically no tenderness of the nerve trunk at all; further, the ankle-jerk is by no means invariably lost. A suggestive feature of these cases is the tendency of the pain to radiate, especially in the distribution of the fifth lumbar nerve root. It is quite common, for example, for the pain to appear first in the region of the outer side of the ankle or the outer aspect of the dorsum of the foot, not infrequently also round the head of the fibula. It is very uncommon, on the other hand, to find the pain referred to the sole of the foot or the actual calf of the leg. This so to say selective incidence of the pain upon the area supplied by the fifth lumbar nerve root, as compared with the areas innervated by the other roots constituting the great sciatic nerve, must in my opinion influence our views of the etiology of the symptoms.

At this juncture I should like to interpellate this question for your consideration. Why is sciatica so common? The correct answer to this question should provide a valuable clue to the problems of diagnosis and treatment. But can we find the answer?

#### *Scoliosis.*

There is one important symptom often associated with sciatica to which I have not yet referred—that is, scoliosis. In a certain number of the cases which do not yield rapidly to treatment and in a very large proportion of the chronic cases a scoliosis may be observed. It may be one of two kinds—the contralateral or the homolateral type. Of these the more common is the contralateral form. In this form a lateral flexion of the lumbar spine away from the affected side may be seen. Attempts by the patient, or the more forcible efforts of the observer, to correct this deformity immediately cause pains in the distribution of the affected sciatic nerve. Associated with this scoliosis in nearly every case is a rigidity of the lumbar spine, with defective flexion and extension as well as impaired lateral movements. Moreover, it is often possible, especially in thin subjects, to palpate an unusually firm and contracted condition of the erector spinae muscle.

There can be, I think, no doubt that this form of scoliosis is due to a muscular contraction, reflex in nature, exactly analogous to that with which we are so familiar in disease of joints elsewhere in the body. In this type of case with a contralateral scoliosis it is interesting to find further confirmation of the suggested lumbar vertebral site of the lesion in the not uncommon experience of a preserved ankle-jerk in association with severe sciatic pain; further, as Harris<sup>2</sup> has pointed out, saline injections of the nerve trunk are not as a rule successful in giving relief in those cases showing a contralateral scoliosis. This form of scoliosis will, as far as the lumbar articulations are concerned, produce a tendency to a wider separation of the articular surfaces of the intervertebral joints and enlargement of the intervertebral foramina on the side of the sciatic pain.

Less commonly found is the homolateral type of scoliosis, where there is a lateral flexion of the spine to the side of the affected nerve. One effect will be to lessen any possible tension on the roots or trunk of the nerve on that side. Harris<sup>2</sup> states that this form of scoliosis is readily amenable to treatment by the injection of saline solution into the trunk of the nerve at the sacro-sciatic notch or midway

between the great trochanter and the tuberosity of the ischium, an experience suggesting very strongly that in those cases with a homolateral scoliosis the lesion is probably a neuritis or a perineuritis of the nerve trunk itself.

Much less common than these two varieties of scoliosis is an alternating form, now homolateral and now crossed in the same patient. Putti<sup>2</sup> believes that these cases are due to a bilateral arthritis of the lumbosacral joints, and that the varying nature of the deformity is due to the need felt by the patient to rest the joints first on one side and then on the other.

#### THE CAUSATIVE LESION.

Enough has already been said to make clear my belief that in a large number of what I have provisionally called the primary or essential sciaticas the lesion probably lies higher up than is often supposed—in the neighbourhood, in fact, of the lumbar vertebrae themselves. We grant at once the existence of a true sciatic neuritis affecting the nerve trunk or its constituent roots in the plexus, in the latter case an intrapelvic situation. But there yet remains the large group where the symptoms suggest a vertebral or at any rate a juxta-vertebral lesion. This group demands close attention.

For the views I am about to put before you I claim no originality. They are based on those of the French school, notably the work of Sicard<sup>1</sup> and of Putti, as well as other orthopaedic surgeons. My excuse for asking you to consider them carefully is the fact that these conceptions have as yet found little mention in English textbooks. According to Sicard neuralgic pains in the distribution of a spinal nerve root, nerve plexus, or nerve trunk can be classified topographically as follows.

1. Neuralgias due to lesions of the posterior nerve roots within the spinal theca; to such the term "radiculitis" has been applied.
2. Neuralgias due to lesions between the posterior root ganglia and the origin of the nerve plexus. This condition Sicard has called "funiculitis," the funiculus being the name given to that part of the nerve root between the ganglion and the plexus. (It will be noted that the funiculus is that part of the nerve root which is mostly contained in the bony canal formed by the intervertebral foramina.)
3. Neuralgias due to lesions either of the nerve plexus or of the nerve trunk itself.

Sicard lays especial stress on the conception of funiculitis, and, since this lesion occurs in the situation of the intervertebral foramina, has coined the term "neurodocite" or "neurodocitis," indicating thereby some inflammatory lesion of the bony canal through which the nerve root passes, and by which the root is irritated.

It will be noticed that radiculitis is a lesion within the subarachnoid space, where the roots are still bathed by the cerebro-spinal fluid. Such lesions are not very common, if we except the syphilitic processes (including tabes), herpes zoster, and various forms of acute spinal meningitis.

The funiculus is a part of the nerve roots subjected to possibilities of very diverse types of lesions, traumatic and arthritic; and the region of the lower lumbar spines, especially the articulations between the fourth and fifth lumbar vertebrae and the fifth lumbar and the sacrum, is particularly prone to be affected, for reasons which I hope soon to give you.

The fact that a neuralgia is unilateral is, as Sicard points out, an argument in favour of an extra- as opposed to an intra-meningeal lesion—of a funiculitis rather than a radiculitis.

It is surely clear that the muscular contractions causing the rigidity of the spine and the scoliosis which we have already considered are powerful arguments in favour of such a conception as that of neurodocitis.

An examination of the cerebro-spinal fluid will provide, again according to Sicard, a further distinction between radiculitis and funiculitis. He states that in radiculitis a lymphocytosis of the fluid is found, while in funiculitis there is a characteristic condition of an increase in the protein without any increase in the cells, the "dissociation albuminocytologique" of the French authors. Greenfield and Carmichael<sup>3</sup> have found this increase in albumin in cases of sciatica up to as much as 0.1 per cent.—a very great increase. These authors state that in the cases with

a high albumin content the pain was severe and symptoms marked, suggesting an active process.

Sicard describes three clinical varieties of sciatica as follows:

1. High sciaticas—that is, those due to funiculitis or neurodocitis.
2. Middle sciaticas—those due to lesions either of the plexus or of the trunk of the nerve from the sacro-sciatic notch to its entry into the thigh proper.
3. Low sciaticas—those due to affections of the nerve in the popliteal space or of its external popliteal division in the leg.

His class of high sciaticas would include, therefore, those which I have here designated as vertebral or juxta-vertebral; the class of the middle sciaticas embraces those common forms of sciatic neuritis or perineuritis; while the low variety is formed by those cases of a more or less localized neuritis or perineuritis of a nerve lower down in the thigh and popliteal space, and even of the external popliteal nerve in the leg or just above the ankle.

It is perhaps easier to follow Putti, who calls the high sciaticas "central" and the middle and lower forms "peripheral." This last division is useful, as it follows what I consider a difference in the usual etiology of the cases, the central forms being those due to vertebral lesions, while the peripheral forms are those to which the term of neuritis or perineuritis is more properly applied.

If this conception of the central forms of sciatica be accepted as due to a vertebral lesion, probably of the nature called by Sicard a neurodocitis—a term whose meaning I have already discussed—we have still to find the answer to the question, Why is sciatica so common? or, to put it in another way, Why should the lower lumbar region of the spine especially suffer in this respect?

The anatomical peculiarities of this region appear to afford a satisfactory explanation. Danforth and Wilson,<sup>4</sup> in an interesting paper, have reported the results of their observations on the anatomy of the lumbosacral region in relation to sciatic pain. They found the intervertebral foramen between the fifth lumbar vertebra and the sacrum to be the smallest, and that between the fourth and fifth lumbar vertebrae the next smallest in this region. This is surely a significant fact.

These authors think that, anatomically, nerve pain due to joint lesions might occur, as regards the fourth lumbar nerve root, from (1) lesions in the intervertebral canal, and (2) at the lower margin of the sacro-iliac joint close to the great sacro-sciatic notch; and as regards the fifth lumbar nerve root, from lesions (1) in the intervertebral canal, (2) at the lateral margin of the joint, between the body of the fifth lumbar vertebra and the sacrum, and (3) at the lower edge of the sacro-iliac joint. They conclude by expressing the view that sciatic pain of the type studied is a symptom of disturbance in the lower lumbar spine, and that the site of the lesion is most frequently the lumbosacral junction, and the nerve chiefly involved is the fifth lumbar nerve.

I have already pointed out how in many cases the pain radiates especially, and sometimes solely, in the distribution of the fifth lumbar nerve root—for example, along the outer part of the leg below the knee and the outer aspect of the region of the ankle.

Other anatomical considerations are also of importance. It is well recognized that the fifth lumbar vertebra is peculiarly liable to congenital variations, of which the most striking is that termed "sacralization," though it is unlikely that this sacralization is often of itself responsible for sciatic pain. Putti has called attention to the frequency of various anomalies in the articular facets of the lumbar vertebrae, and especially of the fifth lumbar vertebra, which, he says, may alter the shape of, or reduce the capacity of, the intervertebral foramen, sometimes on one side only. Finally, the importance of the fifth lumbar vertebra as the foundation stone, as it has been called, of the whole spinal column must ever be borne in mind.

To Putti the central sciaticas are synonymous with a spinal arthritis, which he claims can always be demonstrated by good lateral and stereoscopic skiagrams. In this respect I must admit that my experience has been less fortunate.

Enough has been said, I hope, to convince you that there

are at least good grounds for supposing that in many cases of sciatica a vertebral lesion exists, probably of the nature of an arthritis, and that the nerve root principally affected is the fifth lumbar root.

But even when we have satisfied ourselves that our case of central sciatica is due to a lesion involving the nerve root or roots in the intervertebral canals we have yet to find the cause of this particular form of arthritis. This may be no easy task. Careful search for foci of infection must be made just as in other forms of infective arthritis elsewhere in the body. Teeth, tonsils, accessory sinuses, alimentary tract, and genito-urinary tract must all receive due consideration. I have already indicated my own experience of failure in establishing cause and effect in most cases in this matter of focal infection, but nevertheless I believe it is the right practice to make a careful search and treat adequately any infective foci found. And in this connexion it is well to remember the possibilities of a gonococcal infection, even of some antiquity, as a cause of the more chronic forms of inflammatory lesions of the spinal column. Such considerations, however, must never lead us to neglect the prompt symptomatic treatment of any case of severe sciatica.

From time to time the view is expressed that disease of the sacro-iliac joint is a common cause of sciatica. It will be readily appreciated from the brief anatomical digressions I have made that, theoretically at least, such a combination of cause and effect might easily occur. Actually, however, I believe the event to be rare, although I confess it is a possibility difficult to disprove. Certainly cases seldom if ever exhibit the classical symptoms of sacro-iliac disease, but these, it must be remembered, are those of an advanced disease of the joint, generally of a tuberculous nature. Quite minor inflammatory affections of the joint would certainly be very difficult to detect, both clinically and radiographically, although they might well be associated with sciatic pain.

There is, however, a considerable body of opinion, especially in America, which believes very strongly in the relation between sciatic pains and minor subluxations or strains of the sacro-iliac joint. This belief does not as a rule, I think, meet with general acceptance here, but it is a hypothesis well worth careful testing. Hoyt Cox<sup>7</sup> has recently well summarized certain American views on this point. He distinguishes two types of sacro-iliac subluxation: (1) the traumatic form, usually, of course, acute, which may follow a fall or a heavy lifting strain; and (2) a postural form, usually chronic, due to long-continued faulty postures. In this form the back is unduly flat, the lumbar curve obliterated, and the ilium tilted forwards at an abnormal angle with the sacrum. The chronic forms may also result from infections, with subsequent relaxation of the ligaments of the joint.

It is in this second or chronic type that sciatic pains are likely to form one of the principal symptoms of a clinical picture in which the following signs may also be found: (1) an undue prominence of the sacrum; (2) a rigidity of the spinal muscles; (3) an obliteration of the normal lumbar curve; (4) a lateral curve of the spine away from the affected side; (5) marked tenderness on pressure over the affected joint.

#### DIAGNOSIS.

According to Hoyt Cox x-rays are of little help in diagnosis, a fact which perhaps partly explains the hesitation with which these opinions on sacro-iliac subluxations are apt to be accepted. He states that the "pathological process consists of a definite displacement forwards of the ilium from the sacrum at the upper part of the joint, produced by extreme hyperextension of the spine, together with the strong muscular pull on the anterior part of the ilium."

The effects of trauma, however, are not confined to the sacro-iliac joint. There are obvious possibilities of injuries to the bony components of the lumbosacral region of the spine, and especially of the fifth lumbar vertebra, and fractures, even without displacements, are certainly capable of producing sciatic pain by involvement of the fifth lumbar nerve root itself, or of constant pains in the region of the buttock, referred later, perhaps, down the leg as well,

from involvement of the posterior primary division of this root. But, bony lesions apart, muscular and ligamentous injuries may lead to the formation of scar tissue which may implicate nerve fibres, perhaps of the superior or inferior gluteal nerves, leading to pain in the buttock and pains referred to the sciatic distribution. Such cases demand a clear appreciation of the site and nature of the injury before suitable treatment can be instituted.

#### TREATMENT.

It is obvious that in this, as in every condition in medicine, successful treatment depends on an accurate diagnosis, although palliative treatment may, of course, temporarily relieve all the symptoms. The treatment of the secondary forms of sciatica is clearly that of the causal factor, but where that is unfortunately not amenable to direct treatment we must be content with methods designed to mitigate discomfort and suffering.

Let us consider first the treatment of those cases where a real neuritis or perineuritis of the nerve is present. As previously indicated, a careful search for etiological factors will have been made, and any diabetic element in the case noted and treated. In the severe and acute cases rest in bed is nearly always essential. The application of a splint to the affected leg is sometimes advised, but in my experience this can seldom be tolerated; indeed, the maintenance of any position of the limb for long at a time is often almost impossible. Undoubtedly the most useful local method for the relief of pain is the application of heat in some form or another, whether this be achieved by poultices, fomentations, radiant heat, or diathermy. The last, when available, is a most useful method. Ultraviolet rays with the mercury vapour lamp or the tungsten are applied locally are also of value in the relief of pain.

Many authorities think highly of the value of electricity, either in the form of the simple constant current or of ionization. I must confess to having been little impressed by these methods of treatment, and now seldom employ them. For slighter cases some benefit may be derived from counter-irritation, whether this be effected by strong liniments or ointments, or by blisters, or by the old-fashioned method of painting with concentrated hydrochloric acid, but in any severe case such methods are generally of doubtful value. In the early stages of an acute neuritis massage is definitely contraindicated.

I cannot deal in any detail with all the innumerable drugs which have been used in this disease, either as supposed cures or as mere relievers of pain. Any condition amenable to medicinal treatment, such as constipation or urinary infections which may be a factor in the causation, must, of course, receive prompt treatment. The salicylates and the iodides are about the only drugs which seem to have any direct effect on these cases. The intravenous injection of sodium iodide has been advised, but I cannot say that I have found this method to possess any particular advantage over the ordinary form of medication by the mouth.

Analgesic drugs will nearly always be needed in cases of any severity, especially for the relief of pain at night. Aspirin, phenacetin, phenazone, may all be tried; "dialaceticin" is a useful compound, and I have also found "allonal" of value. A mixture of drugs which I have found effective is a cachet containing 5 grains of aspirin, 5 grains of pyramidon or amidopyrin, and a small dose of heroin, say one-eighth or one-quarter of a grain. It need hardly be said that the use of morphine should be restricted as much as possible, although in really bad cases its use for a time will be almost imperative.

Cases of sciatic neuritis which do not yield fairly rapidly to treatment along these lines, say in two or three weeks at most, may be very advantageously treated with injections of saline solution into the nerve trunk—a method which marks a distinct advance in our therapeutic armamentarium. This method is particularly indicated in cases where there is definite evidence of the presence of a true neuritis, such as marked tenderness on pressure of the nerve and loss of the ankle-jerk. The best sites for the injection are just below the sacro-sciatic notch and at a point on a level with the tuberosity of the ischium. The method is now well known, so that I need not enter into all the details, but it is important to make certain that

A man, aged 30, was admitted to St. Bartholomew's Hospital on June 16th, 1927, having been sent up by his doctor on account of irregular fever. The history was as follows. He was in his usual health until May 7th, 1927, when he had an attack of unsustained pain which lasted four hours and was severe enough to double him up; later that day he vomited three or four times. He felt better the next day and continued at his work; but three days later, not feeling in his usual health, he consulted his doctor.

The patient was ordered to bed and stayed there until his admission to hospital some six weeks later. During the whole of this time until June 9th he had no definite symptoms or signs beyond feeling ill and becoming progressively weaker. From June 9th to June 16th, approximately five weeks after the onset of his illness, he had a rigor every day. There was nothing in his family or past history of importance relating to his present condition, and he had never been abroad.

On admission he looked very toxic and ill; he had a muddy complexion and a drawn anxious expression, and there was great emaciation. Temperature 99.8° F., pulse 120, respirations 30. He was not jaundiced, the tongue was dry and furred, and the breath was offensive. There was a slight fullness in the right lower chest extending downwards to the right hypochondrium: the respiratory movement of the right side was restricted. Vocal fremitus was absent in the right axilla and right base, the percussion note being much impaired and the breath sounds weak over this area. There were no added sounds in the lungs, and the left lung was normal. The heart was normal. The abdomen moved well on respiration; there was a slight fullness in the right hypochondriac region continuous with that in the right lower chest. The liver dullness was increased to the fourth rib above in the mid-clavicular line, but it did not extend downwards beyond the costal margin. There was no tenderness or rigidity even on deep palpation over the liver, spleen, or right iliac fossa. The spleen and kidneys were not felt. The urine was normal. A white blood count showed 27,000 cells per c.mm.

On June 17th the right chest was explored in the seventh intercostal space in the post-axillary line, with negative results. Next day, under x rays, it was seen that the right dome of the diaphragm was abnormally high and that its movements were limited. The diagnosis of right subphrenic abscess was suggested. On June 19th the right subphrenic space was explored, with negative results. During these few days his temperature rose to 103° F. each evening, and fell to 99° each morning. The pulse varied from 130 to 120, the respirations were 25. There were no rigors.

During the next few days his general condition became worse and the physical signs changed. The conjunctivae became slightly jaundiced, his spleen became palpable, and there was epigastric tenderness. In addition there was now a definite outward bulging of the right hypochondrium, and the liver was palpable below the level of the costal margin. A white blood count showed 27,000 cells per c.mm.; a differential count revealed a polymorphonuclear leucocytosis. Blood culture was negative.

On June 25th the patient was extremely ill; he was seen for the first time by Mr. T. P. Dunhill, who made a diagnosis of right subphrenic abscess or hepatic abscess, and advised an exploratory laparotomy. This was performed on the same day by Mr. Dunhill, nitrous oxide gas and oxygen being the anaesthetic, together with local anaesthetic (1 per cent. solution of novocain) for infiltration of the anterior abdominal wall. The abdomen was opened through a right paramedian incision. On opening the peritoneal cavity the liver was found to be much enlarged, a deep purple colour, and intensely congested; it blanched on pressure and was oedematous; there was no perihepatitis. There were some areas paler than normal, and on palpation they felt firmer than the intervening liver tissue, suggesting induration underlying them deep in the liver. The largest of these areas, about three inches in diameter, was situated in the left lobe of the liver, and smaller ones were in the right lobe. It was then decided to explore the indurated area in the left lobe with a syringe. Pus was discovered and about 1 c.cm. withdrawn. The gall-bladder was normal: the portal vein was palpated and appeared to be thickened. The appendix was next examined and found to be surrounded by recent adhesions, the last two inches of it being buried in a loop of mesentery. On peeling it out this two inches was dissected with fluid, which afterwards proved to be mucoous. It was lying in a mass of material which was obviously the remains of an abscess. Appendicectomy was then performed; the peritoneal cavity was packed off and the left lobe of the liver was next opened up with Spencer Wells forceps at the point at which pus had been found; the haemorrhage was considerable, but no more pus escaped. A rubber drainage tube was inserted deeply into the liver and held in position by a catgut suture, two other sutures controlling the haemorrhage. The abdomen was then closed.

The pus from the liver was examined pathologically and proved to be Gram-negative coliform bacilli.

**After History.**—Pus was discharged in large amounts through the drainage tube for the first few days, and then the quantity gradually diminished. The temperature varied from 100° to 93.4° F., pulse from 130 to 110, respirations 26. The patient felt better, the appetite rapidly improved, and he slept well. On the fourth day after the operation the white blood count showed 22,800 cells per c.mm. On the eighth day the drainage tube came away with the dressing; the temperature dropped to normal, and blood count was 7,200 cells per c.mm. He made an untroubled recovery and was discharged on the twentieth day. He was seen again on November 23rd, when he was in the best of health and had regained his normal weight.

The interesting features of the case are: (1) The mildness of the signs and symptoms from the beginning of the illness, including the attack of appendicitis, up till the onset of the rigors some five weeks later. (2) The interval which elapsed between the attack of appendicitis and the onset of suppurative pyelophlebitis and hepatic abscess, as indicated by the rigors. (3) The slight jaundice, profound

toxaemia, rapid prostration, enlarging liver and spleen associated with the onset of portal pyaemia, and leucocytosis.

The whole story is typical of this condition, except for the fact that the patient recovered. The significance of the case lies in the importance of draining the liver and in the proof it affords that the condition, although one of extreme gravity, is not necessarily fatal.

While in St. Bartholomew's Hospital the patient was under the care of Dr. C. M. Hinds Howell and the Surgical Professorial Unit, to whom we wish to express our thanks for permission to publish the case notes.

## THE EXAMINATION OF URINE FOR PUS.

BY

CUTHBERT DUKES, M.D., M.Sc., D.P.H.,

DIRECTOR OF RESEARCH LABORATORY, ST. MARK'S HOSPITAL, LONDON.

THE presence of pus in the urine can only be established certainly by microscopical examination. Other methods of testing for it, such as the guaiac and caustic potash tests, or simple turbidity estimations, only give positive results when much pus is present; they are open to many fallacies because they are not in any way specific. Microscopical examination requires some preliminary preparation of the urine; this has been hitherto effected by centrifuging or sedimentation. A method which obviated preliminary preparation would be an advantage, because the apparatus necessary for centrifuging is not always available, and it may be inconvenient to wait while the cells of the urine settle in a conical vessel. Moreover, each of these methods has certain inherent disadvantages too often overlooked. In the case of the centrifuge the faster the revolutions and the longer the time revolved the more numerous are the formed elements swung to the bottom of the tube, so that a diagnosis of pus is more likely to be made by the owner of a powerful centrifuge than by one who relies on simpler apparatus. The disadvantages and fallacies of sedimentation are so obvious that it is surprising to see such methods still trusted. The rate of sedimentation depends on so many variable factors, and the cells are often unrecognizably deformed consequent on the increased alkalinity accompanying bacterial fermentation.

The following method of microscopic examination of urine for pus can be performed immediately the urine is voided. The test is completed in two or three minutes, and the only apparatus required is a microscope, a pipette, a ruled slide, and cover-glass. The method has the great advantage also of expressing the amount of pus quantitatively as cells per cubic millimetre, a procedure of special value in those doubtful cases in which one observer reports "excess of leucocytes" and another "small quantities of pus." It allows also a record to be kept of the progress of the disease, the increase or decrease of pus being registered as easily as the temperature and pulse.

*Method of Counting Leucocytes in Urine.*

The formed elements of the urine (casts, red blood corpuscles, and leucocytes) are enumerated in a counting chamber by a method similar in principle to that employed for blood counts. The chamber differs in that the glass cell is 0.2 mm. in depth and not 0.1 mm. as in the ordinary haemocytometer, and the area of the ruled lines is 16 sq. mm. The Fuchs-Rosenthal slide for enumeration of cells in the cerebro-spinal fluid is very suitable for this urine test and the one now recommended, but other cerebro-spinal fluid chambers providing a depth of 0.2 mm. may be easily adapted. The ordinary haemocytometer cell is unsuitable because the volume enclosed in it is too small. The ruled area of the Fuchs-Rosenthal slide encloses a square, each side of which is 4 mm. in length, the enclosed space therefore being 16 sq. mm. (See Fig. 1.) This large square is divided into sixteen smaller squares, distinguished by being bordered by three lines, each of which encloses one square millimetre. Each of these is again divided into sixteen squares, bounded by sides 1/4 mm. in length. Since the cell is 0.2 mm. in depth (this being the distance between platform and cover-glass) the volume enclosed in the whole cell is  $16 \times 0.2 = 3.2$  c.mm.

The urine to be tested is shaken thoroughly to distribute the cells evenly; a sample is then taken with a clean rubber test pipette, and a drop of the urine is transferred to the platform of

the slide and allowed to run between the platform and cover-glass. A minute or two having been allowed for the formed elements to settle, the cells are counted by moving the ruled slide to and fro across the microscope stage until the whole ruled area has been surveyed.

The most convenient objective to use for this purpose is an 8 mm. or 1/3 in. dry lens providing an initial magnification of about 20. This objective with a  $\times 10$  eyepiece includes comfortably in its field of view four of the smallest squares (see Fig. 1, A), and this permits the whole field of 16 sq. mm. to be surveyed in eight light and four from right to left, 200 (diameters) leucocytes and red easily.

Most microscopes in common use are provided with only two dry lenses, a 16 mm. or 2/3 in., and 4 mm. or 1/6 in. The 8 mm. objective recommended for this test is intermediate between the two; it is well worth while to exchange the 16 mm. for an 8 mm. objective for cell count work. The test can be performed with the 4 mm. or 1/6 in. objective and a low power eyepiece, but, although the magnification is quite satisfactory, the microscope field is much more restricted than with an 8 mm. or 1/3 in., so that only one of the smallest squares is completely enclosed in the field of view. (See Fig. 1, B.) Thus sixteen journeys must be made—eight from left to right and eight from right to left—before the whole field has been surveyed. The 16 mm. or 2/3 in. objective, although offering a wide microscope field (Fig. 1, C), does not provide sufficient magnification, even when combined with a high eyepiece, to permit distinction between leucocytes and bodies which closely resemble them in size and shape. It may be used for the rapid examination of a urine almost free from cells, but if formed elements are present in the urine it will usually be necessary to re-examine the field with a higher objective to determine what should or should not be counted. A mechanical stage is almost indispensable. In an emergency the count can be made without a movable stage if the observer has acquired sufficient dexterity to move the slide by hand, but a mechanical stage saves time and energy and ensures much greater accuracy. Unless pus is present in large quantities all the sixteen large squares must be counted—that is, the whole ruled area. The volume thus surveyed is 16 sq. mm. by 0.2 mm. = 3.2 cubic millimetres. The number of cells observed in the whole ruled area divided by 3.2 gives the number of cells per cubic millimetre. It is sufficiently accurate for practical purposes to count all the cells in the sixteen squares and divide by 3. If pus is present in such large quantities that each microscope field shows several cells, then the survey of all the 16 sq. mm. may mean counting several thousand cells. For such specimens a shorter method is sufficient. Only the first four of the sixteen 1 mm. squares need be counted, and the figure obtained is multiplied by 4 and divided by 3 to give the cells per cubic millimetre.

FIG. 1.—Ruling of Fuchs-Rosenthal slide magnified nine times. A=field of view with 8 mm. objective and  $\times 10$  eyepiece; B=field of view with 4 mm. objective and  $\times 5$  eyepiece; C=field of view with 16 mm. objective and  $\times 10$  eyepiece.

cytes and bodies which closely resemble them in size and shape. It may be used for the rapid examination of a urine almost free from cells, but if formed elements are present in the urine it will usually be necessary to re-examine the field with a higher objective to determine what should or should not be counted. A mechanical stage is almost indispensable. In an emergency the count can be made without a movable stage if the observer has acquired sufficient dexterity to move the slide by hand, but a mechanical stage saves time and energy and ensures much greater accuracy. Unless pus is present in large quantities all the sixteen large squares must be counted—that is, the whole ruled area. The volume thus surveyed is 16 sq. mm. by 0.2 mm. = 3.2 cubic millimetres. The number of cells observed in the whole ruled area divided by 3.2 gives the number of cells per cubic millimetre. It is sufficiently accurate for practical purposes to count all the cells in the sixteen squares and divide by 3. If pus is present in such large quantities that each microscope field shows several cells, then the survey of all the 16 sq. mm. may mean counting several thousand cells. For such specimens a shorter method is sufficient. Only the first four of the sixteen 1 mm. squares need be counted, and the figure obtained is multiplied by 4 and divided by 3 to give the cells per cubic millimetre.

#### Leucocyte Content of the Urine in Health.

A few leucocytes are often found in the urine of healthy men and women who give no history of any disease of the genito-urinary organs. Whether or not such cells are physiological, or represent the after-effects of some morbid lesion too slight to evoke symptoms, is a question on which urologists have held different views. For practical purposes it is generally admitted that if only an occasional leucocyte or two is found in a centrifuged urine after searching several fields of the microscope, the urine may be regarded as normal; but the fact that a few leucocytes may be present in the urine of healthy people necessitates a definition of the normal limits before a numerical definition of pyuria is possible.

The cell count method of examining urine for pus has been applied to more than 700 samples of urine; of these examinations 411 were of men and women free from genito-urinary disease and 291 were of cases of urinary sepsis. The summary of results obtained with normal men and women is recorded in the following table.

	Nn. of Counts.	No. of Individuals.	Maximum Count.	Minimum Count.	Average Count.
Healthy men ...	288	157	50	0	2.1
Healthy women ...	123	85	50	0	7.1

#### A Numerical Definition of Pus.

A total of 291 counts has been made on patients suffering from various diseases of the genito-urinary tract, including nephritis, pyelitis, cystitis, prostatic abscess, urethritis, stone in the ureter, and many undetermined inflammations. Insufficient data have been collected to permit any sort of classification of the pus counts of different pathological conditions; for the present purpose they are grouped together as individuals suffering from some disease of the genito-urinary tract in whom the diagnosis of pyuria was justified. The counts ranged from 100 to 5,000 leucocytes per c.mm. In most cases of acute inflammation a leucocyte count higher than 500 cells per c.mm. was obtained; in more quiescent or chronic cases the figure was less than 500. Experience has shown that a count of more than 100 leucocytes per c.mm. points to disease of the genito-urinary tract, and justifies the designation pyuria. Urine should be described as containing pus when more than 100 leucocytes are present per c.mm. This allows of a very generous margin above the average count of 2.1 cells per c.mm. for men and 7.1 for women, but such a wide margin is advisable because of the normal range of variation. What significance, if any, should be attached to counts between 50 and 100 will probably have to be decided separately for each individual case when other sources of information have been explored.

#### Comparison with Previous Standards for Pus.

In deciding whether or not a urine shall be said to contain pus reliance is sometimes placed upon the number of leucocytes seen per field of the microscope after the urine has been allowed to settle or been centrifuged. Obviously no comparison is possible between the standard now recommended of 100 leucocytes per c.mm. and the number of cells per field of the microscope, because the thickness of the drops adds yet another variable factor to those already mentioned inherent in the process of centrifuging and sedimentation. Comparison was made with other methods by adding leucocytes to normal urine until the tests became positive and then counting the cells, and by diluting pus-containing urine with normal urine until the tests became negative and again counting the cells. These comparisons, repeated on many occasions, only served to emphasize how crude and full of pitfalls are all methods for the detection of pus other than by the microscope. These comparisons may be summarized in a sentence by saying that urine which is clear from every other possible cause of turbidity must contain more than 400 leucocytes per c.mm. before the pus causes sufficient opacity to be detected by the naked eye, and the guaiac test and liquor potassae test are often negative with urine containing more than 500 cells per c.mm.

#### The Examination of Urine for Blood.

The cell count method of estimating pus is applicable also to the study of haematuria. An occasional red blood corpuscle may be found in the urine of healthy people, but except after injury or disease of the genito-urinary tract, or during menstruation in women, there are always far fewer red blood corpuscles than leucocytes. The discovery in the urine of more than 2 or 3 blood cells per c.mm. is an important observation, but the counting of the cells has no practical value except when both red blood cells and leucocytes are found, and the question is raised whether the condition is one of uncomplicated haematuria or whether blood and pus are both present. When both red and white corpuscles are enumerated the cell count method will decide this question, thereby showing whether or not the relationship existing in the blood of one leucocyte to 500 red blood cells is maintained or exceeded in the urine.

First count the red cells per cubic millimetre of the urine (after suitable dilution if necessary) and divide by 500 to give the number of leucocytes expected to accompany this quantity of blood. Then count the number of leucocytes per cubic millimetre actually present in the urine (after taking the red cells with acetic acid if necessary), and if this figure per cubic millimetre exceeds the estimated figure by more than 100 pus is present in addition to blood.

The delicacy of the cell count method for detection of blood is proved in a convincing way when a comparison is made between this and other methods. It was noticed during routine testing, and has been frequently verified by

the simple experiment of adding blood to urine and then counting the cells, that all methods of testing for blood other than microscopic are not only valueless, but a positive source of deception. The guaiac test for blood is hardly ever positive unless the urine is red in colour, and experiment has shown that more than 10,000 red blood corpuscles must be present per c.mm. before this point is reached. The pyramidon and heazidine and spectroscopic tests are only positive when the urine is either obviously red or has a "smoky" tint, "smokiness" being reached only when the urine contains at least 1,000 red blood corpuscles per c.mm. When less than 1,000 red blood cells are present per c.mm. no test other than the microscope will show the presence of blood. On the other hand, the cell count method may be relied on when such small quantities of blood as 10 red blood cells or even less are present per c.mm. The delicacy of the cell count method is revealed when these facts are presented in an example. A specimen of urine containing about 800 to 900 red blood corpuscles per c.mm. would show no smokiness and no trace of blood to the naked eye, and the guaiac, benzidine, and spectroscopic tests might all be negative, and yet the presence of blood would be indisputably demonstrated by the cell count method after the urine had been diluted more than one hundred times.

#### Practical Points.

The specimen of urine to be examined should be the first passed in the morning, and the patient should be instructed to pass the urine direct into a wide-mouthed bottle, or into a clean receptacle from which it is to be transferred at once to a clean bottle. The figures given above are based on early morning specimens; lower counts are obtained if a specimen is collected only an hour or two after the bladder has been emptied and the patient has taken a lot of fluid. Specimens may be accepted if an interval of more than four hours has passed since the last micturition, but in all doubtful cases the early morning specimen must be insisted on. The urine should be examined on the day on which it is passed.

#### Turbid Urines.

Urine need not be clear from crystalline or amorphous deposit of inorganic salts, but if these are dense accurate counting becomes impossible. A cloud of phosphates may be quickly dispelled by a drop of acetic acid. A deposit of urates and oxalates cannot be easily removed by any chemicals, but urine turbid from this cause usually becomes quite clear by dilution with an equal volume of warm water.

#### Recognition of Leucocytes.

Only round cells of the size and shape of leucocytes must be counted. Until the eye has become trained to

FIG. 2.—Field of view obtained with 8 mm. objective and  $\times 10$  eyepiece, enclosing four  $1/4$  mm. squares, reduced for reproduction to one-fifth of the size actually seen. Red blood corpuscles in upper left-hand square and leucocytes in lower right-hand square.

red blood cells have been drawn to scale, and in the lower right-hand square leucocytes. An impression of the relative size of things can be obtained by recollecting that each of these smallest squares is bounded by lines 250 microns in length. Red blood cells in urine usually measure 8 to 9 microns in diameter, a little less than  $1/25$  of the boundary

line, and leucocytes usually measure 10 to 12 microns, a little more than  $1/25$  of the boundary line.

Epithelial cells must not be included in the count. These are usually larger, often irregular in outline, with a relatively small conspicuous nucleus. Squamous cells are easily distinguished and disregarded; caudate cells with a tail-like prolongation of the body, and pear-shaped cells, usually attributed to the renal pelvis or neck of the bladder, must not be included in the count. In judging whether or not a cell should be counted as a leucocyte special attention should be paid to the size, the definite rounded outline, and the presence of a nucleus. The recognition of a leucocyte is an accomplishment that becomes progressively easier with experience. No advantage is gained by trying to stain the cells, and the so-called differential stains purporting to distinguish epithelium from blood cells are unreliable. Acidifying with acetic acid makes the cell nuclei more conspicuous, but with experience in the counting of leucocytes even this simple step is usually unnecessary.

#### Recognition of Red Blood Cells.

Red blood corpuscles are more difficult to distinguish than leucocytes, and it is well before attempting to count erythrocytes to become familiar with the shapes they may assume, whether the disc is viewed through the centre or periphery. Accurate measurements are necessary in doubtful cases.

#### Storing of Apparatus.

After use the slide and cover-glass are conveniently disinfected and stored in methylated spirit. The glass pipette should be well rinsed out with water and stored standing in a test-tube containing 1 per cent. formalin. After use for a urine containing much pus the pipette should be boiled or thrown away. The pipettes are made by drawing out glass tubing in the blowpipe flame, and it is useful to have about a dozen at hand.

#### Summary.

The most accurate method of determining whether or not pus is present in urine is to count the leucocytes in a chamber similar to that used for counting the cells in cerebro-spinal fluid. The sample to be tested must be the first urine passed in the morning or after an interval of four hours. The test can be completed in two or three minutes, and provides a quantitative record comparable from day to day. It is suggested that no urine should be said to contain pus unless it contains more than 100 leucocytes per c.mm.

## SARCOMA OF THE STOMACH.

BY

JAMES S. HALL, M.B., B.S.LOND., F.R.C.S.ED.,  
SURGEON, VICTORIA HOSPITAL, DEAL.

THE following case presents so many features of interest, apart from the extreme rarity of the condition, that it seems worthy of record. Most of the surgical authorities consulted either make no reference to the incidence of this type of growth or else quote it as a "rare pathological curiosity." In this instance the only practitioner to diagnose the case as one of malignancy was the anaesthetist, who was not acquainted with the physical signs or the clinical history.

A man, aged 40, was first admitted to the Victoria Hospital, Deal, on April 14th, 1927, under my colleague the late Dr. F. M. S. Hulke. The diagnosis made on admission was chronic duodenal ulcer. The history was typical: pain an hour or two after food, slightly relieved by food, melaena, some wasting. A skiagram after a barium meal confirmed this diagnosis. There was a rapidly acting stomach with considerable deformity of the duodenal cap, no filling defects, no sign of crater in the lesser curvature, and, to complete the picture, an apparent duodenal ileus.

Dr. Hulke commenced medical treatment, and the results were excellent. The patient put on weight, a stone or more, regained his healthy appearance, and was discharged fit a month later. After three months of rather strenuous work he came to consult me with a view to operative treatment of his condition. His previous good health had disappeared, he was emaciated, had frequent vomiting, and melaena with a good deal of pain and discomfort. He was therefore readmitted to hospital on August 15th for a preliminary course of rest and dieting, as his condition was too poor to risk immediate operation. During the following

week he had so much tenderness and rigidity in his epigastrium that no tumour could be felt. After the first week he was considerably better; the vomiting and melaena had ceased.

**Operation.**—On August 22nd he was taken to the theatre with a view to removing the appendix and performing duodeno-jejuno-stomy. Under general anaesthesia a movable epigastric tumour, about 4 inches in diameter, was felt through the abdominal wall and explored through a right paramedian incision. It proved to be a growth of the middle of the stomach, slightly adherent to the pancreas, with multiple glands in the gastro-hepatic and gastro-colic omenta. I removed the growth with the enlarged glands and a small portion of pancreas by the modified Polya method, leaving about a quarter of the cardiac end of the stomach to anastomose to the side of the jejunum. Convalescence was uneventful.

Macroscopically the stomach showed two large ulcers about 2 inches in diameter, facing each other on the anterior and posterior walls, with very thick heaped-up edges and obvious neoplasms in their bases. A section of one was sent to a pathologist, who reported as follows: "This is a difficult specimen about which I felt doubtful. A second opinion I obtained was given as follows: 'The gastric wall is occupied by small polygonal cells of connective tissue type and oat-shaped form. Being almost absolutely uniform in character, without admixture with chronic inflammatory cells, the condition cannot be related to a hyperplastic gastritis or leather bottle condition. The diagnosis would be spindle-celled sarcoma.' I hesitate to accept this diagnosis as the condition would be extremely rare, and I think there are other possibilities. Without knowing anything of the clinical condition, I do not care to express a definite opinion."

Having fortunately preserved the specimen I forwarded a section of the growth from the other ulcer and an enlarged gland. A second report read: "This is evidently a deposit of small round-celled sarcoma which has become ulcerated, a very rare condition. The gland does not appear to be affected."

The patient was seen again four months after the above account was written; he had then gained 2 st. in weight and all signs of malignancy had disappeared.

From a surgical point of view one would certainly say from the specimen that the sarcoma supervened upon chronic ulceration, but that is a pathological point I am not qualified to dispute.

The salient points of the case are rather remarkable—the clinical evidence of duodenal ulcer, the condition found at operation, and the points against malignancy, especially the considerable improvement after rest and diet. I have no information as to the prognosis of these cases, if, indeed, any have been operated upon before.

I would like to express my thanks to Dr. Ponder for the pains he has taken to give me an accurate statement of the microscopical condition of the growth.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### MECKEL'S DIVERTICULUM IN STRANGULATED INGUINAL HERNIA.

The following case, in which a Meckel's diverticulum was found in a strangulated inguinal hernia, seems worthy of record.

A married woman, aged 66, was admitted to the Royal Infirmary, Liverpool, in October, 1927, with a history of having been acutely ill for three days with a lump in the right groin, abdominal pain, and vomiting; strangulated inguinal hernia was diagnosed. There was a tender, tense, rounded swelling at the lower end of the right inguinal canal; the skin moved freely over it, and there were no signs of inflammation of the cutaneous tissues. The patient stated that she had had a rupture for some years, and that three days before admission, while exerting herself, a sudden severe pain had appeared in the groin, causing her to vomit.

On opening the sac some sanguineous fluid escaped, and a tube was discovered about three inches long, and intensely congested at its distal end. This tube had a small mesentery, and at first sight I took it to be the appendix. On pulling out the portion of bowel to which it was attached, however, a loop of small intestine presented instead of the caecum. After ligaturing and dividing the mesentery (or meso-diverticulum) the tube was clamped at its base, the stump invaginated, and the loop of small intestine returned to the abdomen. The sac was removed in the usual way and the inguinal canal repaired.

The patient made an uninterrupted recovery and no complications have arisen since.

Pathological examination of the tube showed the structure to be typical of a Meckel's diverticulum.

HUGH RED, M.B., F.R.C.S.,  
Honorary Assistant Surgeon, Royal Infirmary,  
Liverpool.

## UNUSUAL COMPLICATIONS OF PNEUMONIA.

In view of the exceptional symptoms, course, and complications the following case of pneumonia appears to be worthy of record.

A man, aged 65, when first seen complained of headache, slight headache, and "cold chills." He had not had a rigor, and did not look very ill. His tongue was very dry and red; the pulse was 100, the respirations 20, and the temperature 101.5° F. Physical examination was negative. The next day he had a slight cough, with a little yellow sputum. The chest was resonant, with a few rales at both bases. He had no pain. On the third day the cough had almost gone and the general condition was the same. On the fourth day he had severe hiccup, which continued almost without pause for two days. He also had slight conjunctival jaundice. On the fifth day jaundice became very deep over the whole body, and the abdomen was greatly distended, though no cause was found. The patient passed a small, soft yellow stool, and the urine was

On the sixth day the jaundice returned, and there was a suspicion of the right lung. The pulse was 100, and the temperature 103° F. The abdomen was still greatly distended; and on this day a hard, globular swelling about the size of an orange was noted in the left iliac fossa. This had a clear edge below, but the upper margin was ill defined; there was a resonant note over it, and it did not move on respiration.

The diagnosis up to now had been influenza with mild bronchitis, and later early pneumonia, possibly. The jaundice presented a difficulty, but was recognized as occurring rarely in influenza. The distension was attributed to a condition of paralytic ileus due to profound toxæmia. The lump could not be explained, and was the chief difficulty.

Dr. J. H. Thornley, honorary surgeon to the Scarborough Hospital, saw the case in consultation, and agreed to take the man into hospital. During the following day the patient became gradually much worse, and died that evening with definite signs of a right-sided pneumonia.

At the necropsy marked pneumonia was found in the lower lobe of the right lung; the heart contained ante-mortem clot. There was no lump within the abdomen, but a large hæmatoma was present in the abdominal wall.

The unusual points in this case are: (1) The huge hæmatoma. I cannot find a record of this occurring in the abdominal muscles during influenza and pneumonia. I would suggest that the cause was thrombosis of a vessel in the abdominal wall. (2) The marked jaundice.

I am indebted to Dr. Thornley for the later history of the man, for the necropsy findings, and for helpful suggestions generally.

Scarborough.

N. WALSH, M.B., Ch.B. Leeds.

## Reports of Societies.

### ANAESTHETICS IN OBSTETRICS.

At a joint meeting of the Sections of Anaesthetics and Obstetrics of the Royal Society of Medicine on March 2nd, with Dr. Cecil Hughes, president of the Section of Anaesthetics, in the chair, a discussion was held on anaesthetics in obstetrics.

Mr. EARDLEY HOLLAND, opening the discussion from the obstetric standpoint, said that he was glad to see that obstetricians were beginning to take an interest in anaesthetists of their art which hitherto they had almost neglected. The requirements of the obstetrician were that the anaesthetic should be simple and safe in administration, and capable of being used by those inexperienced in the use of general anaesthetics. Pain must be abolished and, if necessary, kept in abeyance for long periods of time, but there must be no interference with the force or frequency of the normal uterine contractions, or with the safety of the mother and the foetus. Chloroform and ether were equally good anaesthetics, but the latter needed more expert administration, as it was more difficult to ensure quick results and required more elaborate apparatus. Stovaine was useful in certain obstetric operations, but was not advised in "common labour." Morphine was a good analgesic for the mother, but was dangerous to the foetus. For common labour he believed that intermittent chloroform, as administered by Simpson, its originator, was the best way of ensuring relief from pain. If administered by means of a Junker bottle with a small hand-bulb it was difficult to give an overdose, and so an unskilled person

could be allowed to administer it in the presence of the obstetrician. Chloroform should not be given until the second stage of labour was beginning. In the first stage fairly large doses of chloral (30 grains) might be given, and if necessary repeated; morphine and hyoscine in small doses were also useful. These ensured relief from pain without marked interference with the uterine contractions. Mr. Holland pleaded that Simpson's method should be taught to students. It was difficult to keep patients in the first stage of anaesthesia without practice. It was a reproach to obstetrics that in hospitals and in the practice of midwives common labour should be conducted without the use of chloroform or some other general anaesthetic. The first stage of anaesthesia was ample to relieve pain for the second stage of labour, and with it there was relaxation of the levator ani muscle, with consequent shortening of the time of labour, as there was less resistance to the passage downwards of the head. The anaesthesia needed deepening towards the end of this stage, when the head was engaging the cervix and stretching it. He referred also to the effect of emotion on labour pains. Suitable mental treatment was valuable during the last months of pregnancy, so as to ensure the co-operation of the patient by gaining her confidence. Pain was greatly increased if a patient were unduly apprehensive or frightened by tales told by her friends. Psychic treatment tended to make the ordeal less terrible, and she went through it with far less emotion.

Dr. JOSEPH BLUMFIELD agreed as to the desirability of anaesthetics being given in common labour, but denied that anaesthetists had only just commenced to take an interest in obstetric anaesthesia. Their opportunities had been limited hitherto by lack of invitations to co-operate with the obstetricians. In his opinion nitrous oxide and oxygen, owing to the bulk of the apparatus necessary for their effective administration, could not be used as a routine in private houses. Moreover, it was difficult to give these gases in a wide bed such as was commonly used for parturition. They caused a condition of excitement in many people which militated against proper asepsis for the accoucheur. He believed chloroform was the anaesthetic of choice. Regarding synergistic analgesia, he was surprised at the choice of this route of anaesthesia. The pelvis was already full, and it was proposed to add several ounces of fluid. Ethylene and acetylene, excellent for producing quick loss of consciousness, were unsuitable if the anaesthesia had to be prolonged. Ethyl chloride was very useful, and could be used repeatedly in small doses without any ill effects on the patient.

Mr. W. GULLATT said there were three types of confinements: (1) among the poor and in hospital; (2) in a doctor's practice, where the practitioner gave the anaesthetic and conducted the confinement; and (3) among the wealthier classes, where an obstetrician and an anaesthetist were employed. In the first group an anaesthetic was not usually given. Chloroform was the most useful anaesthetic in the second group, and where a skilled anaesthetist was employed, as in the third group, the choice of anaesthetic could safely be left to him. Chloroform certainly delayed delivery more than did ether, and the use of this anaesthetic increased the probability of forceps being needed. On the other hand, the immobility of the patient which followed chloroform lessened the chance of contamination of what should be a sterile field. Probably nitrous oxide, oxygen, and ether were the ideal anaesthetics for confinements, but these necessitated the presence of a skilled anaesthetist, and so had to be ruled out of court as the routine procedure. Chloroform had its dangers, and might lead to changes in the liver and kidneys; any existing toxæmia might be increased by its use, and if a second operation subsequently became necessary chloroform was very risky, and should not be used on any account. Spinal anaesthesia with stovaine was useful for Caesarean section, but should not be given with an inhalation anaesthetic, even of nitrous oxide, as lung complications were very likely to ensue.

Dr. H. A. RICHARDS said the selection of an anaesthetic for a woman in labour depended on the state of the patient, just as in general surgery. The first anaesthetic could consist of any suitable drug, but on no account

should a second anaesthetic contain any chloroform. Nitrous oxide was not suitable when the patient was in a state of apprehension of pain, as it only tended to excite her, and chloroform could be dispensed with in cases of Caesarean section. If stovaine were used he recommended that a small dose, such as 0.4 cg. in saline solution, should be given. If nitrous oxide were used he preferred to give it without oxygen, but with air, and possibly with a little carbon dioxide.

Dr. H. E. G. BOYLE had been much impressed with what he saw in the United States, where nitrous oxide and oxygen were given to a great extent. So far from being diminished, he believed that the uterine contractions were increased both in force and frequency, and the length of the labour thereby shortened. A little ether should be added when the head was being born. This could be cut off before the body was delivered, and oxygen and carbon dioxide substituted. After the birth of the body the nitrous oxide and oxygen should be continued until the placenta was delivered.

Dr. BECKETT-OVERY believed that in the hands of the unskilled nitrous oxide and oxygen were dangerous; chloroform could be given by the woman herself with the help of a Junker inhaler. During the first stage he liked to give morphine and hyoscine, as it led to calm and quiet.

Mr. SYDNEY MALKIN said that he had had a limited experience with synergistic analgesia and thought it might be useful. Of twenty cases analgesia had been entirely successful in twelve; two failed completely; one patient showed undue excitement; in one case, with a quick second stage, the child was born blue, and the rest were not entirely satisfactory. Dr. CLARKE strongly approved chloroform, both in obstetrics and in general surgery. When properly given, according to the Scottish method, it was both safe and satisfactory. Dr. Z. MENNELL believed that the method of nitrous oxide and oxygen as used in America was excellent in America, where all obstetric cases were dealt with in private and public hospitals, but that in this country it was impracticable because of the drawback of lack of portability of the apparatus.

#### MEASUREMENT OF BASAL METABOLISM.

At a meeting of the Liverpool Medical Institution on February 16th, with the president, Dr. JOHN HAY, in the chair, Dr. H. S. PEMBERTON and Dr. R. T. GOODYEAR made a communication on the clinical value of basal metabolism measurement.

Dr. Pemberton, dealing with the clinical side, compared this method of measuring thyroid activity with the well-established tests of functional efficiency of other tissues, and defined it as the measurement of resting heat production or minimal oxygen consumption under basal conditions. He contended that it now had, or should have, its place in the diagnostic armamentarium of the modern general hospital. In discussing the practical value which might be obtained from a knowledge of the basal metabolic rate, he drew attention to four questions: (1) In the case of apparent hyperthyroidism or goitre, what was the actual level of thyroid activity? (2) In cases in which there were no definite signs of altered thyroid activity was there, in fact, an alteration in so far as this was expressed by an abnormal basal metabolic rate? (3) The success or otherwise of treatment as reflected in a movement of the basal metabolic rate towards normal; guidance from this movement as to subsequent treatment; and a comparison between alternative methods of treatment. (4) The prognosis as measured by the basal metabolic rate.

Dr. Goodyear described in detail the working of the modified Benedict instrument in a room especially set aside for the purpose. The production of the basal state, the many factors which influenced it, and the difficulties in technique were discussed. The standards of Aub and Du Bois were those upon which estimations were based. He laid stress upon the careful preparation and the handling of the patient while undergoing the test, and particularly the lighting, decoration, and heating of the basal metabolism room. The reliability of the results was also discussed in detail.

## Rebels.

### EDEN AND LOCKYER'S "GYNAECOLOGY."

THE third edition of EDEN and LOCKYER'S *Gynaecology*<sup>1</sup> will receive a hearty welcome, for it has already established itself as one of the soundest and sanest presentations of the subject published in this country. From the first the authors set themselves the difficult task of striking an even balance between the pathological and the clinical aspects of gynaecology, and they are to be congratulated on having maintained that balance throughout successive editions. From the standpoint of those specially practising and teaching this branch of medicine the thorough manner in which the pathological side is treated has made it essential for them to find a place for this volume on their bookshelves. It gives in small compass a judicious summary and world-wide review of the advances in gynaecological pathology, particularly in morbid histology.

This edition has called for considerable addition both to text and illustrations. The physiology of menstruation—both the histology of the endometrium throughout the cycle and the influence of the corpus luteum—has been revised in the light of recent research, including the work of Wilfred Shaw on the formation and structure of the yellow body. Other new matter calling for mention is the full account of adenomyoma—or endometrioma, as it is now more often termed—and its place in the causation of the tarry blood cysts of the ovary, as worked out by Sampson and Bailey. The book has, too, a correspondingly valuable practical side, and the more modern means of diagnosis and treatment are fully considered and weighed. The section on operations is clearly written and well illustrated; the attention paid here to the after-treatment of both abdominal and vaginal operations is particularly worthy of notice, and must prove of value to those who have the after-care of the patients as well as those who operate.

The section on cancer of the uterus provides a good example of the authors' skill in combining the scientific and practical sides of their subject. The naked-eye and microscopic characters and the mode of spread of the various forms of uterine cancer, together with their features as found on clinical examination in their early and late stages, are fully described and illustrated, and possible lines of treatment, operative and otherwise, and selection of cases are carefully discussed. Treatment by radium is regarded with an open mind and optimistic outlook, and the technique for its application is exemplified by figures showing a front and side view with a tube in the canal and needles palisading the periphery of the growth. The dosage advised is, however, smaller than that commonly adopted. The difficulty in reaching glandular and cellular-tissue metastases is stressed, and deep x-ray radiation advocated for them.

The inclusion of puerperal sepsis in the infections is greatly to be commended, for it cannot be reasonably separated from other infections of the female genital tract, although customarily it is allocated to obstetrics. Good use has been made of the old surgical division of the subject into general and regional, but we question whether this classification is any less open to the objection the authors make to a pathological classification—that it tends to dissociate conditions which are in close clinical relation.

This new edition of a good book deserves all the appreciation accorded to its predecessors.

### FRACTURES.

SCUDDER'S *Treatment of Fractures*<sup>2</sup> is recognized as a leading authority wherever the English language is spoken or read, and the issue of the tenth edition will be welcomed by all who have to do with these injuries—that is to say, by every medical practitioner—for the spread of the motor

car epidemic makes it impossible for any man to foresee when or where he may be called upon to treat a fracture. We are not surprised to learn from Dr. Scudder that the incidence of fractures is increasing in the United States, but the figures he quotes are appalling. He tells us that in 1924 155,000 cases of fracture were treated in "A Grade" hospitals in that country. How many cases should be added for hospitals of lower grade we cannot tell, but the figures above quoted signify that one person in seven hundred suffered from fracture in one year and was fortunate enough to be admitted to hospitals of A grade. This new edition has been brought thoroughly up to date, the operative treatment being especially fully discussed and described, including both plating and grafting methods. The importance of team work is emphasized. For the first time Dr. Scudder has, in this edition, confined the articles on special subjects to specialists. Dr. Joseph C. Bloodgood writes on pathological fractures, Dr. F. W. Bancroft on bone repair, Dr. Kurt H. Thoma on fractures of the maxilla and mandible, Dr. James Menoll on massage, Dr. Frank Richardson on anaesthesia and anaesthetics, and Dr. Edward Truesdell on birth fractures, a subject that he is peculiarly qualified to deal with. Dr. Scudder recognizes that if better functional results in fractures are to be attained, treatment, especially in difficult and complicated cases, should be carried out by specialists, or at least by general surgeons who have had special experience, and that such treatment should be initiated as early as possible, if it is to give good results.

The publishers of Dr. ETIENNE'S *Traitement des Fractures par le Praticien*<sup>3</sup> say that "this little book has been written for the practitioner who, in the presence of a fracture, without radiographer, special apparatus, or skilled assistance . . . has to decide on and apply treatment." Any practitioner in such a predicament has our sincerest sympathy, for the absence of radiography alone presupposes that he is fighting with one hand tied behind him, and that he may be the victim of an action for malpraxis. This is a handy little guide to the rudiments of fracture treatment, and contains useful hints as to first-aid. Unlike most Continental surgeons, the author seems to have some knowledge and some appreciation of the merits of Thomas's splints. The figure which purports to represent the conditions in a fracture of a vertebral body does not show the ordinary compression fracture, but a fracture-dislocation, which is uncommon. In the case of a fracture of the patella we are told that there is only one logical method, and that that is open operation and "corlage." How the practitioner in the circumstances presupposed by the publisher is to carry this out we do not know. No other method of treatment is so much as alluded to.

### BIRTH INJURIES OF THE NERVOUS SYSTEM.

DRS. FORD, CROTHERS, and PUTNAM, in their book on *Birth Injuries of the Central Nervous System*,<sup>4</sup> have attempted to arrive at a more exact definition of the group of true birth palsies than has been hitherto attained. The subject of "cerebral" birth injuries is dealt with by Dr. Ford, who states that there is convincing evidence that the congenital diplegias which constitute by far the largest group of infantile spastic palsies are not to be attributed to meningeal haemorrhage at birth, but are the result of various pathological processes of intrauterine origin. Cerebral birth injuries producing lesions of a kind that would lead to congenital diplegias he considers to be rare, and he concludes that the great majority of infantile palsies can no longer be lightly attributed to faulty obstetrical procedures. As regards hydrocephalus, no final statement can be made about its relation to birth injury. Marked enlargement of the head may occur, with extensive bleeding into the ventricles or subarachnoid spaces; but

<sup>1</sup> *Gynaecology for Students and Practitioners*. By Thomas Watts Eden, M.D., C.M., F.R.C.P.Lond., F.R.C.S. Ed., and Cuthbert Lockyer, M.D., N.S., F.R.C.P., F.R.C.S. Third edition. London: J. and A. Churchill, 1928. (Roy. 8vo, pp. xv + 822; 555 figures, 32 plates, 3ss.)

<sup>3</sup> *Traitement des Fractures par le Praticien*. Par Dr. Etienne. Préface du Professor Jeanbrau. Paris: Masson et Cie. 1927. (8½ x 7½, pp. 194; 145 figures. 16 fr. sans.)  
<sup>4</sup> *Birth Injuries of the Central Nervous System*. By Frank R. Ford, P. Crotthers, and Marian C. Putnam. London: Baillière, Tindall and Co. 1927. (8½ x 7½, pp. 57 figures. 38s. net.)

"Cerebral Birth Injuries" by Bronson Vol. XI. xiii + 164;

usually the blood becomes absorbed, though possibly hydrocephalus may result occasionally from plugging of the iter. The common diffuse meningeal haemorrhage, which is not large enough to cause death, apparently leaves no residuum as a rule. The real birth injuries to the brain are caused by the rarer intracerebral haemorrhages and necroses, by depressed fractures with laceration of the brain, and by some encapsuled haemorrhages which compress and soften the cortex. The true birth palsies are apparently represented, not by the diplegias, but by the congenital hemiplegias, the monoplegias, and the asymmetrical and unequal bilateral spastic paralyses; asymmetrical congenital defects of the brain will, however, be unavoidably included in this group since they are clinically indistinguishable. If this view is correct it would appear that only about 6 per cent. of all infantile cerebral palsies are due to birth injury, but the group is not well enough defined to permit of exact numerical estimation. Recurrent convulsions occur in about one-third or more of these cases, and it is probable that about 2 or 3 per cent. of all epilepsies seen in children are related to birth injury. Severe grades of mental defect are probably not related to birth injury, with the exception of that type which develops in association with frequent convulsions.

Birth injuries of the spinal cord are considered by Crothers and Putnam. The ordinary type of brachial palsy is well understood; it is produced by traction, usually lateral, and in general is characterized by paralysis of definite groups of muscles. In a number of cases, however, where the disability was paralysis of the arm, the authors found evidence that the spinal cord was also involved, and they have come to the conclusion that in most cases where the spinal cord is affected the cause has been traction exerted during delivery and not congenital or other pre-natal influences. The most fragile and least elastic structures, they contend, are the spinal cord, the membranes protecting it, and the nerves, and it is these structures which are liable to suffer from undue traction. The authors note that obstetrical textbooks are almost completely silent on this point; and they consider that until more emphasis is placed on the importance of the control of traction as a factor in successful delivery, accidents will occur in unnecessary numbers. If no adequate warning is given by teachers that traction may result in serious injury to the spinal cord, the individual practitioner may use it to the detriment of the children he delivers.

#### SYNOPSIS OF SURGERY.

POPULAR books seem to grow in bulk with every new edition, and the eighth edition of *A Synopsis of Surgery*<sup>2</sup> by Mr. E. W. Hey Groves, is no exception. It would almost seem that it has outgrown its original title, and that the present volume is deserving of a more imposing name. Written as it is in short, concise sentences, on subjects well and extensively classified, it covers such an enormous and increasing field that it is in danger of becoming more a book of quick and easy reference than a "crum" for the student on the threshold of his surgery examination.

With each edition new work is introduced on various subjects without elimination of that which has become obsolete. Not that anyone desires the latter to pass into oblivion, for it can be retained in all the larger textbooks, but its reappearance in a synopsis tends to make the book top-heavy. For example, the older forms of treatment for syphilis, and such operations as necrectomy and nerve stretching, could be dispensed with, and for facial tie stretching is advised and no mention made of alcohol injections. Recent work, such as cholecystography and ventriculography are mentioned, and lipiodol injections could usefully have been included with these, also the relation of the vertebral spines to the spinal segments, rather than its enlargements. Several black-and-white illustrations have been incorporated in the text, and as an appendix there is a chapter on surface markings.

<sup>2</sup> *A Synopsis of Surgery*. By Ernest W. Hey Groves, M.S., M.D., B.Sc.(Lond.), F.R.C.S.(Eng.). Eighth edition. Bristol: J. Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. 1927. (Cr. 8vo, pp. viii + 674; 146 figures, 13 plates, 17s. 6d. net.)

All students will find in these pages what is necessary for their pass examinations, a great deal of practical help and wisdom to guide them in their period of hospital apprenticeship, and concise references on most of the important points of surgery likely to arise in the course of busy general practice.

#### NORMAL HISTOLOGY.

THE thirteenth edition of *Piersol's Normal Histology*,<sup>6</sup> revised, and in part rewritten, by Professor ADDISON of the University of Pennsylvania, shows a welcome advance, though all too small, in the physiological treatment of the subject. Histology is the easiest subject to master in the medical curriculum, and the easiest to teach. Hence it is too often taught in uninteresting fashion, and the student fails to obtain that familiarity with the minute anatomy of the normal tissues, as distinct from the "spotting" of organs, which is so necessary for the later study of morbid anatomy. The decay of morbid anatomy is partly due to lack of vision in histological teaching.

As an example of the anatomist's outlook the book is satisfactory, and many new illustrations have been added, notably those showing vascular injections of various organs. Considerable space is devoted to those organs which are examined in the *post-mortem* room, and the section dealing with the blood has been amplified. From the point of view of the physiologist the work suffers from an inadequate description of the appearance of freshly examined tissues and from a lack of historical consciousness of the continuity and interrelationship of form and function in the work of all the masters in this subject. There is a useful appendix of routine methods and a list of selected references based on the reading lists that are such a feature of American seminars. This list includes about 165 titles, of which 130 are purely American. The student would benefit in his reading if he were made acquainted with some of the giants of histology, such as Kölliker, Ranvier, and Virchow among the earlier, and Sobotta, Schaffer, and Schäfer among the more recent. The description of the blood vessels is still inadequate, and the statement that the intima of the veins sometimes contains muscle is not in keeping with the description in Piersol's textbook of anatomy. We find no reference to the Rouget cells of the capillaries, or to the work done thereon by Clark of Philadelphia, or to the direct examination of the circulation of the blood in the kidney described by Richards of the same school, and the masterly Harvey Lecture by Gideon Wells on calcification and ossification is omitted from the reading list.

The section dealing with the nervous system is in keeping with the anatomical tradition, but suffers from brevity. The histology of degenerating nerve is still omitted. The clinical and pathological significance of Wallerian degeneration is one of the main weapons of the histologist, and the most important of the few that he has. The stria of Gennari in the visual cortex is not figured or described. At a time when increasing attention is being paid to metaplasia of tissues, senescence, and normal decay, it seems a pity that the histology of the ductus arteriosus, ductus venosus, allantois, Wolffian duct, and foetal oesophagus should be omitted, for the student will surely hear of them during his later studies in morbid anatomy.

#### NOTES ON BOOKS.

*Treatment by Manipulation*<sup>7</sup> is the second edition of Mr. TIMBRELL FISHER's *Manipulative Surgery*, which was reviewed by us in our issue of December 26th, 1925 (p. 1231). We do not quarrel with Mr. Fisher's change of title, although a captious critic might object that all surgical treatment is treatment by manipulation, for the cheirourgus is essentially a manipulator. The sections on osteopathy, tennis elbow,

<sup>6</sup> *Piersol's Normal Histology*. Thirteenth edition, now first edited and in part rewritten by William H. F. Addison, M.D. Thoroughly revised and reset. London: J. B. Lippincott. 1927. (Med. 8vo, pp. viii + 477; 432 figures, 25s. net.)

<sup>7</sup> *Treatment by Manipulation*. By A. G. Timbrell Fisher, M.C., F.R.C.S.(Eng.). Being the second edition of *Manipulative Surgery*. London: H. K. Lewis and Co., Ltd. 1928. (Demy 8vo, pp. xi + 209; 62 figures. 9s. net.)

chronic arthritis, and lesions of the sacro-iliac joint have been rewritten and enlarged. As regards the last named, Mr. Fisher's views now approximate to those held by the Boston school in America, but in a book on manipulation we can hardly expect to find a recommendation of fixation operations in extreme cases of subluxation. His discussion of osteopathy and chiropractic is timely, and the instances he quotes of damage done by osteopaths and chiropractors should be a warning to those who are inclined to be indulgent towards such practices, and will furnish valuable arguments to medical practitioners who are trying to guide their patients into safe ways. As regards the elusive syndrome known as tennis elbow, but not confined to tennis players, we note that Mr. Fisher does not mention the method of treatment which has been so successfully used by Mr. G. Percival Mills of Birmingham, and which was described in our issue of January 7th (p. 12). Mr. Fisher's remarks on the value of movement and rupture of adhesions in various cases of chronic arthritis are worthy of notice.

Under the editorial direction of three distinguished surgeons of Berlin, Halle, and Berno, a *System of Urology*<sup>8</sup> is being prepared. The first volume deals with urology generally, and in particular with its surgical anatomy. A careful account is given of operations on the kidneys, ureter, bladder, and male generative organs. The physiology and pathology of the urinary secretion are similarly dealt with on an elaborate scale. The book is copiously illustrated, and there is a useful index. It is a good example of the characteristic type of German publication which endeavours to combine the textbook and the reference volume.

Dr. JOAN ROSS, now lecturer in pathology at the London School of Medicine for Women, brought out in 1925 a book on *Post-mortem Appearances*,<sup>9</sup> which was favourably noticed in these columns (1926, i, 331). It has now deservedly passed into a second edition, which has been revised and enlarged by some additions. The book is a little longer, but there is every reason to repeat what we said on the previous occasion, except those suggestions then made as to slight changes, which have been adopted.

All workers on mosquitos in tropical and South Africa will be greatly indebted to Miss ALWEN M. EVANS for her *Guide to the Anophelines of Tropical and South Africa*,<sup>10</sup> which appears as one of the Memoirs of the Liverpool School of Tropical Medicine. As the author states, "it is not in any sense of the word a monograph . . ." but it is all the more useful to the medical and sanitary officers in these countries, for whom, in fact, the volume is likely to prove indispensable. A key for all adult species and a key for larvae of the six most widely distributed species is given, followed by a systematic and bionomic account of each, with excellent illustrations in the text, and at the end a series of plates of breeding places and many very beautiful delineations of arrangements of scales and tarsus markings.

Volume XLVII of the *Transactions of the Ophthalmological Society of the United Kingdom*<sup>11</sup> contains the proceedings during the past year of this society, and also of the Midland, North of England, and Irish Ophthalmic Societies, and of the Oxford Ophthalmological Congress in 1927. Good illustrations are provided for the various papers, and the present issue, like its predecessors, constitutes a valuable record of progress in ophthalmology in Great Britain.

*Lippincott's Pocket Formulary*<sup>12</sup> requires a somewhat capacious pocket. The volume has been compiled by Dr. GEORGE E. REHBERGER in order to provide the medical practitioner with a ready reference manual. The first section gives an alphabetical list of diseases and symptoms, with appropriate treatment and prescriptions. Some of the conditions may sound quaint to English ears, such as eaked breasts and milk sickness. The latter part of the book contains lists of U.S.P. X drugs, of drugs in the *National Formulary*, and of new and non-official remedies. Sundry tables of weights, measures, and so on are appended.

<sup>8</sup> *Handbuch der Urologie*. Herausgegeben von A. v. Lichtenberg, F. Voelcker, H. Wildholz. Erster Band, Allgemeine Urologie I. Berlin: J. Springer. (Roy. 8vo, pp. x + 754; 312 figures. R.M.33.)

<sup>9</sup> *Post-mortem Appearances*. By Joan M. Ross, M.D., B.S.Lond., M.R.C.S., L.R.C.P. With a preface by E. H. Kettle, M.D. Second edition. Oxford Medical Publications. London: Milford, Oxford University Press. 1928. (Fcap. 8vo, pp. ix + 228. 7s. 6d. net.)

<sup>10</sup> *A Short Illustrated Guide to the Anophelines of Tropical and South Africa*. By Alwen M. Evans, M.Sc. Liverpool School of Tropical Medicine, Memoir (New Series) No. 3. London: Hodder and Stoughton. 1927. (7½ x 10½, pp. 54; 10 figures, 12 plates. Paper cover, 7s. 6d. net; cloth, 8s. 6d. net.)

<sup>11</sup> *Transactions of the Ophthalmological Society of the United Kingdom*. Vol. XLVII. London: J. and A. Churchill. 1927. (Demy 8vo, pp. xlviii + 467; 82 figures, 3 plates. 30s. net.)

<sup>12</sup> *Lippincott's Pocket Formulary*. By George E. Rehberger, M.D. London: J. B. Lippincott Company. 1927. (4 x 8½. 15s. net.)

## LIVER EXTRACT IN THE TREATMENT OF PERNICIOUS ANAEMIA.

REPORT BY THE MEDICAL RESEARCH COUNCIL.

THE following preliminary report on the liver treatment of pernicious anaemia has been received for publication from the Medical Research Council.

The treatment of pernicious anaemia by addition of liver to the diet, introduced in America by Minot and Murphy, has already been widely adopted with encouraging results. An important development of this has recently become possible through the successful preparation, by Cohn and others, of an extract of liver containing in small bulk the unknown factor which produces the ameliorating effect. The treatment is thereby made available for patients who cannot tolerate the large daily consumption of liver itself.

In the past autumn, through the courtesy of the Pernicious Anaemia Committee of Harvard Medical School, the Medical Research Council received information about this method of preparing liver extract, and were invited to make trial of it with a view to assisting introduction of the treatment in this country. On the basis of this information experimental work was undertaken in the Council's laboratories at the National Institute for Medical Research, and a modification of the American process was found, through the co-operation of Professor F. R. Fraser of St. Bartholomew's Hospital, to yield a satisfactory extract. To increase the scope of the work the Council then invited the co-operation of manufacturing firms likely to be interested, and arrangements were made for clinical trials of the preparations thus obtained in adequate quantity.

Supplies of liver extract made on a manufacturing scale by the modified process were received from the Boots Pure Drug Company, from the British Drug Houses, Limited, and from Messrs. Burroughs Wellcome and Co.

It is at present impossible to gauge the therapeutic effects of liver extracts in pernicious anaemia by any other method than that of direct trial upon human patients. The extracts supplied by the three firms were, therefore, distributed widely to various hospitals, and clinical reports upon the activity of the several preparations have been received from the following physicians: Dr. John Cowan, Glasgow; Dr. S. P. Davidson, Edinburgh; Professor E. C. Dodds, Middlesex Hospital; Professor T. R. Elliott, University College Hospital, London; Professor A. W. M. Ellis, London Hospital; Sir Thomas Houston, Belfast; Professor W. E. Hume, Newcastle-on-Tyne; and Professor E. Mellanby, Sheffield. To these, and the colleagues who have been associated with them in this work, the Council are much indebted.

A total of 34 apparently clear cases of the disease came under treatment. The object of the trials was to test the activity of each extract as rapidly as possible, rather than to watch the results over a long period of time. For this purpose the early increase in the count of reticulocytes—the young red cells with special staining properties—was adopted, as it had been found to be satisfactory in the American work. This rise is usually associated with clear sensations of improvement on the part of the patient, and it is succeeded by a progressive increase in the general red cell count, while the relative proportion of reticulocytes diminishes.

Out of the 34 cases all but 2 showed a good response. In 23 of these the conditions were such that other reasons for the improvement than the administration of the extract were clearly excluded. In the remaining 9 the response during treatment was no less marked, but the possibility of natural remissions or the influence of other treatments, such as previous administration of fresh liver, rendered the conclusion less certain. The daily dose of extract, corresponding to half a pound, or 250 grams, of liver, generally brought a clear rise in reticulocytes, culminating about the twelfth or fifteenth day; double that amount daily excited an earlier reaction, with a maximum as early as the fifth day. As illustrating the remoter benefit in a case that had been treated with only the smaller doses, but over a longer period, the total red cell count rose from 750,000 to 5,000,000 in thirty-four days.

These effects are identical with those obtained with liver itself, although the effect of a given dose of the extract is not so great as that of the quantity of liver from which it is

derived. Time has not yet permitted an estimate of any possible deterioration of the extract on keeping.

These preliminary reports enable the Medical Research Council to state that the preparations submitted have been found to be satisfactory. The process used in making these extracts has not necessarily any peculiar value as compared with possible alternatives, but it is one capable of ready application on a large scale. The Council believe that further progress will be best facilitated if extracts of the type which they have investigated are now made available, along with any others introduced apart from the Council's action, to the medical profession in general.

It is understood that supplies of these liver extracts will at once be obtainable, through the usual commercial channels, from the firms already named. The Council are not themselves able to deal with any applications for the material.

## THE GLASGOW MEDICAL JOURNAL.

### A CENTENARY NUMBER.

A HUNDRED years have passed since Dr. William Mackenzie launched the first number of the *Glasgow Medical Journal* upon the waters of Scottish medical life. His name and a list of the appointments which he held occupy such a prominent position on the title-page of the first number that it is fair to assume that even if he did not himself build the ship, his at least was the hand that knocked away the dog-shores and allowed the vessel to glide down the metaphorical ways, as so many tall ships and ocean liners have done on the banks of the actual Clyde. This centenary occasion is celebrated by the publication of a commemorative number which consists entirely of historical articles and notes, and is illustrated by a number of portraits and views. It includes also papers on medical journalism by Sir Dawson Williams and Sir Squire Sprigge.

Sir Dawson Williams's contribution—which now has a sad interest as being the last of the few articles he ever signed—traces the origin of newspapers to the newsletters of business firms, such as the great Augsburg house of Fugger, whose system, at first intended only for their own use, was afterwards extended, so that their periodical dispatches were allowed to be copied and sold to the public. This interesting article is illustrated by reproductions of the title of the earliest French medical paper, the *Journal de Médecine* of 1683, and the first British one, the *Medicina Curiosa* of 1684, of which latter only two numbers are known to have been published. Our late Editor recalls that the first person to issue a newspaper in the modern sense—that is to say, a printed sheet published at regular intervals—was a Doctor of Medicine, Theophrastus Rendudot, whose *Gazette* and *Nouvelles Ordinaires* appeared in Paris in 1631.

Sir Squire Sprigge would put back the origin of medical journalism to a date somewhat earlier than 4000 B.C. when an unknown Babylonian physician recorded a case of incurable dropsy on a clay tablet; but he evidently realizes that as one swallow does not make a summer, so one, or even several, clay tablets do not constitute a medical periodical. He assigns the honour of being the first British medical newspaper to the *Foreign Medical Review* of 1780. Other journals followed this, some of which survived the date of the first appearance of the *Lancet*, which in 1823 made a complete innovation in the matter and manner of medical journalism. It had its rivals, as Sir Squire Sprigge tells his readers, among them the *Provincial Medical Journal*, the organ of the great Association founded by Sir Charles Hastings, and our lineal ancestor.

The *Glasgow Medical Journal* resembles perhaps more some of the earlier medical publications in that it has at no time been published at shorter intervals than one month. Indeed, for nearly half the time of its publication it was a quarterly, but since the year 1877 it has appeared regularly once a month. It has long been produced by the Glasgow and West of Scotland Medical Association, of which Dr. J. Wyllie Nichol is president, and the two editors to-day are Mr. John Patrick and Dr. George A.

Allan. The *Journal* has not been without its local rivals during its long career, of one of which there is an entertaining account in the leading article of this centenary number, "The *Glasgow Medical Journal* and its Editors." This was the *Glasgow Medical Examiner*, which had a brief existence in 1831, and was revived in 1869. It became known as the "Mustard Plaster," so called partly from the colour of its wrapper, but still more on account of the blistering qualities of its articles. Even so late as 1869 it ridiculed Lister, congratulating its readers on his removal to Edinburgh and on the hope that "our Alma Mater will no doubt be purified from even the smell of the quackish puffed nostrum" (that is, carbolic acid). Gairdner was bracketed with Lister as a subject of its denunciation. But the *Journal* itself was not always polite in its reviews of books. In 1853 Syme came in for very rough treatment, even being reminded by the reviewer of individual patients whom he had failed to cure.

The principal of the University, Sir Donald MacAlister, has contributed a short note on that school as it was a hundred years ago, when the professor of botany was Sir William Hooker, afterwards director of Kew Gardens, whose son and successor, Sir Joseph, the friend of Darwin and Huxley, died as recently as 1911. The school was flourishing, for at that time the number of matriculated students of medicine was 428. The Scottish universities at that period, and for some time afterwards, had no rivals in Great Britain as regards medical degrees, for Oxford and Cambridge scarcely counted as schools of medicine, and London University was not. Yet few Englishmen seem to have availed themselves of the opportunities offered at Glasgow, for of the thirty-eight degrees granted in 1827 in medicine or surgery, only two were conferred upon Englishmen. Probably Edinburgh offered greater attractions. Sir Donald MacAlister's article is illustrated by a photograph of the picturesque old college in the High Street.

The old universities did not condescend to meddle with the "base mechanic art" of surgery, except in so far as it was studied by physicians who professed to control the practitioners of surgery. Thus in Glasgow, as in London, we find the teaching of surgery in the hands of corporations of less dignity than the universities. The Faculty of Physicians and Surgeons of Glasgow was established by a charter of King James VI in the year 1599, and given authority, among other things, to examine all persons professing the art of chirurgery. It is noteworthy that in the same charter it is enacted that no one is to practise *medicines* "without a testimonial of a famous university quhair medicine be taught." When the University took to granting degrees in surgery, as it did in 1816, competition between it and the Faculty became keen. Despite the prestige of the additional title of "Royal" which was granted by King Edward in 1909, the Faculty finds itself handicapped by the action of the Carnegie Trust, under which many students' university fees are paid. Although the Faculty had furnished surgical teaching to its apprentices, the extramural school really dates from the year 1744, when William Cullen, a physician, founded it by instituting courses of lectures, but Dr. John Henderson tells us, in his article on "The position of extramural teaching in Glasgow," that the era of continuous teaching in Glasgow dates definitely from the establishment of the medical school of Anderson's College in 1799. This very flourishing school at one time called itself Anderson's University, although it was never incorporated as such. It still continues to contribute largely to the educational needs of Glasgow medical students, and among its teachers have been many distinguished men, not the least of whom is the present regius professor of surgery, Dr. Archibald Young. Besides a former school of medicine of the Western Infirmary, the Royal Infirmary has also had its medical school, for which a charter was obtained in 1875, and this school is still carried on, notwithstanding the competition from which it and Anderson's College suffer from the University.

This centenary number contains much more than is of interest, including a paper by Dr. Fergus on the Glasgow hospitals, and the editors, Mr. Patrick and Dr. Allan, deserve congratulations on the result of their labours.

## THE JOHN HUNTER BICENTENARY.

## CELEBRATION AT ST. GEORGE'S HOSPITAL.

THE two Hunterian Societies—one of them the Hunterian Society of London, particularly of the City, founded in 1819, and the other the Hunterian Society of St. George's Hospital, founded in 1832, but not taking the name of Hunter until 1850—united at St. George's Hospital on March 1st to celebrate the bicentenary of John Hunter's birth. The gathering, which was of the nature of a conversation, took place in the board room—not the board room of John Hunter's time, which has disappeared, but on almost the same site. Behind the speakers was the couch on which Hunter died, his portrait was over the mantelpiece, and various prized writings and other relics of him were on exhibition. Dr. HUGH GAINSBOROUGH, who presided, said that St. George's Hospital, in which Hunter worked and died, was the most appropriate of all places for a celebration, for the proudest of many proud boasts of St. George's was its connexion with Hunter.

Sir HUMPHRY ROLLESTON said that the four most famous names in British medicine were those of William Harvey, the physiological physician; Thomas Sydenham, the master of practical medicine; and John Hunter and Joseph Lister, the two greatest surgeons the world had ever known. In two months' time the tercentenary of the publication at Frankfurt of Harvey's *De Motu Cordis*, which marked the birth of experimental physiology, would be duly honoured. The Lister centenary was fresh in the mind, and Sydenham's tercentenary was celebrated only in 1924. It was appropriate that Harvey and Hunter, both students of nature and experimental philosophers, should be linked together in our grateful recollection. Hunter, whose original observations ranged over the whole animal kingdom, including even fossil remains, was the first to describe the circulation in crustaceans and insects, just as Harvey discovered and demonstrated the circulation of the blood in the higher animals. Further, in his great treatise *The Blood, Inflammation and Gunshot Wounds* (1794), Hunter investigated the power of the blood to repair damaged and diseased tissues. Again like Harvey, he studied the earliest stages of life, and left behind him the dictum that "embryology indicates the steps by which higher forms in a group of animals have been evolved from a lower." The more he was known the more wonderful Hunter became, and as the years went by his intellectual standard seemed only to grow grander; anatomy, physiology, pathology, surgery, and biology in its widest sense found in him their master. The acknowledged founder of scientific surgery, and, in Timothy Holmes's words, "the greatest man indeed who ever practised surgery," his original researches and philosophical principles were on such broad lines that they provided the basis for medical science as a whole, and were in no way confined to that branch of the profession which he specially followed, though probably he did more than anyone else to elevate surgery to its proper and high position in medical science. It was therefore not unnatural that a claim was made for John Hunter as a physician; it was made by Dr. Newton Pitt in his learned oration before the Hunterian Society in 1896. But, as Sir Clifford Allbutt eloquently argued, the divisions of the healing art were artificial, and as, to quote Sir Jonathan Hutchinson, "the ideal surgeon is a physician who operates," all branches of the profession, therefore, were surely united in their debt of gratitude to Hunter for his services and example. Hunter had been described as a martyr to science, for the ill health which dogged his later years, and his death in tragic circumstances in 1793, had been ascribed to the effects of his auto-inoculation with venereal pus. This experiment on himself was the self-sacrificing practice of the advice he gave to his distinguished pupil Edward Jenner, to try rather than to speculate, thus recalling Harvey's exhortation to the Fellows and Members of the College of Physicians "to search and study out the secrets of Nature by way of experiment." In Nature's most securely guarded secret—namely, the meaning and source of life—Hunter was keenly interested, and in regard to the much-discussed problem of its mechanistic or vital origin, which the new science of biochemistry might

be hoped to bring nearer to solution, Hunter's philosophical teaching would appear to be in favour of the view that it was a supernatural endowment.

Much had recently been said elsewhere about John Hunter's world-wide pre-eminence in medical science, but in that hospital in which he worked and died, of which he was the chief glory, and where he first instituted clinical teaching in surgery, it was meet and right that the bicentenary of his birth should be specially celebrated. Sir Humphry recalled how in 1893 the centenary of his death was commemorated there by Mr. Timothy Holmes in a fine classical appreciation, and by the erection of Gilbert's masterly bronze bust, which since 1924 had adorned the entrance to the out-patient department and medical school in Knightsbridge.

Sir CHRIS ENGLISH also delivered a brief appreciation. What body of people, he asked, could make the greatest claim to John Hunter? Hunter was born in Scotland, but Scotland did not seem to have appropriated Hunter in the same way as Lister. It might be that Scotland had not taken much notice of John Hunter because, when he came to years of discretion, he left that country and started for the south. The Royal College of Surgeons of England had rather annexed Hunter, but it was worth remembering that Hunter's collection did not reach the College until seven years after his death. It was a remarkable thing that the House of Commons, which so seldom showed any practical interest in science, should have voted a large sum for Hunter's collection, and that at a time when Pitt was calling for money for munitions of war. Leicester Square might possibly put in a claim for Hunter, for there it was he started his collection. In Leicester Square, too, lived Sir Joshua Reynolds, and it had been said of Hunter and Reynolds that each helped the other to immortality, the one as subject and the other as painter. But St. George's claims stood out above all others, for Hunter was first surgeon to the hospital from 1768 until his death. He was never an assistant surgeon, and no doubt was truly grateful for that. He was probably a difficult person to get on with, continually at loggerheads with his colleagues, of whom he wrote as a "damned disagreeable lot." Reynolds's picture, on the other hand, conveyed a different impression of him, which they would like to retain, and Edward Jenner and other pupils, who probably had a better knowledge of him than anybody else, always called him the "dear man." The speaker commented on some curious things in the Reynolds portrait—the expression of power in the face, the uncomfortable position of the left hand, the fact that there were two inkpots on the table, both closed, though Hunter held a pen in his right hand, and the bigness of the right arm as compared, so it seemed to him, with the left.

Mr. R. R. JAMES, dean of the medical school, exhibited the pupils' register for 1756, in which one of the first names entered was that of "Mr. Hunter." He also showed an original letter, dated 1765, which, though written in the third person, was unquestionably, in his view, in John Hunter's hand. In that year there was a vacancy for a surgeon, and the letter was to explain to the board Hunter's position why he did not apply against his rival John Gunning, who obtained the post. Another exhibit was a house-surgeon's certificate of 1769, signed by Hunter and others. The pupils' register of subsequent years, which was also produced, showed the much greater number who entered under Hunter, and reminded one of the famous squabble which reached its climax at the special court in 1793. A poignant exhibit, not for what it showed, but for what it omitted, was the minute book of the weekly board for Wednesday, October 16th, of that year. It was a very small meeting: only four were present. After some trifling matter about coffins and shrouds, which the hospital was going to receive cheaply, it was ordered that Mr. Hunter's letter relating to pupils should be reserved for future consideration, and the meeting passed to the next business. Of the fact that Hunter's death took place in the adjoining room during that meeting there was no mention. Mr. MORTIMER WOOLF, president of the Hunterian Society of London, said that that society existed, not for any claim it could lay to John Hunter, but solely to perpetuate the memory of a great man.

## MEDICINE IN THE FIELD OF LIFE ASSURANCE.

IN the course of a thoughtful address, delivered lately to the Assurance Medical Society, its president, Dr. H. G. Turney, found some interesting things to say about modern developments of life assurance and their bearing upon the world of medicine. He sketched the evolution of the medical examination for assurance from a stage when the examining doctor would submit a laconic "Good" or "Bad" to his directors on the strength of little more in the way of examination than the shrewd appraisal of a seeing eye. But he might have gone a step further back yet, to a day when (in some offices at least) the appraisal was a confessedly lay affair, carried out by the directors after a personal inspection of the candidate.

From these beginnings medical selection gradually won its way, until a day was reached some twenty-five years ago when an observer might justifiably have assigned the future to the medical profession, so far as concerns the selection of lives for assurance. But he would have judged amiss; for at about this time lay opinion in the insurance world, hitherto trending steadily towards the enlargement of medical influence in this sphere, evinced a tendency to branch. While the great majority of those concerned were content to pay increasing tribute to the claims of medical selection, there arose in this country a school of pioneers with the unexpected and reactionary watchword, "Life assurance without medical examination." It is not easy at this distance to appreciate as it deserves the hardihood involved in this daring breach of the acceptances of the day. The scheme, however, was put into effect, at first tentatively and with reservations, and later with increasing boldness; and it succeeded. Since then the system has widened its scope and influence without interruption, though without speed, and may now be said to be common form in a good many institutions.

What is the special appeal of "life assurance without medical examination"? Dr. Turney allots its appeal mainly to the large body of semi-invalid and valetudinarian people who shrink from a medical examination lest it reveal some sinister but as yet happily hidden portent of disaster. We cannot but think he is at fault in this. There are, no doubt, a good many people who approach a medical examination with apprehensions of the kind he describes, but surely it is Dr. Turney's second group—"the average lazy man in the street"—which feels the temptation of the examination-free assurance. Life assurance is a commodity for sale, and one that yields no immediate gratification to the buyer, but rather the reverse. So since a man can get on without it he is likely to be lazy about buying it, though he knows well enough in his heart that it will be good for him. Accordingly, when the agent pins him down and proves to demonstration his need to cover himself against unforeseeable contingencies, he may be in a mood to listen, but he listens under protest and without enthusiasm. And so it comes about that the way he chooses is prone to be the way which will lead him with the least expenditure

of trouble to the end which his reason—but not his indolent habit of mind—has considered and approved.

As to the future of this system, Dr. Turney thinks it has come to stay under certain restrictions, at all events for sums of moderate amount, and he deplors the injury thus inflicted upon the pockets which, in a better-ordered world, would continue to gather the honest guineas thus withheld from the medical profession. We agree that it has come to stay; indeed, we fancy the speaker underrated the firmness of its footing at this minute. Certain it is that an approved life can already obtain cover under this system, without limitation of amount and subject to no other restriction than a generous limit of age. But as regards the guineas, we are fain to believe that the new order entails less prejudice to our cloth than Dr. Turney fears; for though it dispenses with medical examination it is far from dispensing with medical selection. Nay, it leans at every doubt upon medical assistance in the shape of reports from medical attendants. So perhaps we may hope, after all, that a good proportion of the guineas which used to be ear-marked for medical examinations will find a dedication no less honourable under the new dispensation in the discharge of fees for medical attendants' reports. But if in "life assurance without medical examination" we see ourselves faced by a tendency which is, however slightly, uncomplimentary, we may seek consolation in turning to another and more flattering tendency in the opposite direction. This finds its expression in the periodic examination of assured lives at the expense of the assuring offices. The idea underlying the periodic examination is, of course, that under such a scheme a double and mutual advantage will accrue to the parties concerned: the assured will be warned in good time of the errors of addiction or regime into which he has been beguiled by the naughtiness of appetite or the "strength of nature in youth" (as Bacon aptly designates the reserve-against-stupidities by means of which a merciful heaven tides us over the follies of that epoch); while the assuring office is able to rest happy in the confidence that its clients are being maintained in a condition to go on paying their premiums punctually up to the very last unescapable moment.

Periodic examination is, it seems, an American product, though even in its homeland its vogue is strictly limited. Such success as the movement has had in the United States Dr. Turney attributes to "the very large class of people of the Babbitt type who are extremely well-to-do, who have made a fortune in a strenuous business life involving much nervous strain, and who have retired in the prime of life. They have unlimited leisure, with no outside interests to fill it, and it is not long before *tedium vitæ* begins to take its toll of their sense of spiritual and bodily well-being." We are invited, that is to say, to believe that the valetudinarian habit of mind, which drives some men to assure their lives non-medically for fear of the doctor, will equally drive others who belong to the same category into the doctor's consulting room time after time under the system of periodic examination; and it must be admitted that the reactions of the human mind are sometimes bizarre enough to bring even this paradox within the bounds of belief.

Dr. Turney's conclusion is that the periodic examination is not desirable because it will tend to create a race of cranks and hypochondriacs. We wonder whether cranks and hypochondriacs are really so easily made as this conception implies. The deplorable abundance of indifferent health which seems

to be a corollary of sedentary existence may be, as Dr. Turney holds, purely an expression of morbid states of mind reflecting themselves in misdemeanours of the body. But there is an equal likelihood—and more hope—in the view that some kind of physical or chemical misdemeanour of the body is needed to determine the valetudinarian habit, at its beginning at any rate. If this view is the more correct, we need not vex ourselves on the subject of morale; and since it is certain that a great many people are daily running risks of irreparable damage to their bodies owing to their innocent disregard of unappreciated but avoidable perils, it seems almost a pity to impede a movement which is designed to warn them before it is too late.

#### ALKALOSIS AND KETOSIS.

THE effect of the ingestion of alkali upon carbohydrate metabolism has been further discussed by Goldblatt in a recent paper,<sup>1</sup> and the subject is perhaps of sufficient clinical importance to warrant a brief summary of some of the earlier literature. Davies, Haldane, and Kennaway<sup>2</sup> showed in 1920 that alkalosis, produced experimentally by bicarbonate ingestion or overbreathing, caused acetone bodies to appear in the urine. Haldane, Wigglesworth, and Woodrow<sup>3</sup> repeated these results, using themselves as experimental subjects, and found that after overbreathing and after bicarbonate ingestion large amounts of  $\beta$ -oxybutyric acid and small amounts of acetone were excreted. The increase of ketosis after alkali administration to diabetics had often been observed, but had been put down to a "washing-out" effect on the aceto-acetic acid and  $\beta$ -oxybutyric acid already present in the body. The ketosis produced by alkali administration to normal subjects would be difficult to account for in this way, and Haldane, Wigglesworth, and Woodrow thought that it might be due to deranged carbohydrate metabolism, and sought further evidence of such a derangement. The respiratory quotient was found to fall very low about three hours after bicarbonate had been taken, and remained low for several hours. In some cases the quotient was well below 0.7, this showing that no carbohydrate at all was being oxidized during that period. At the same time the sugar tolerance was very much lowered, and the blood sugar curves after taking glucose resembled those given by diabetic subjects. The ketosis, very marked during the experimental period, was only partially suppressed by the glucose, and returned again as the blood sugar level fell. As such results (except, of course, the altered respiratory quotient, which could not be determined in overbreathing) could be obtained either by overbreathing or by bicarbonate ingestion, both of which methods produce alkalosis but otherwise have very dissimilar effects upon the blood and tissues, the authors thought it safe to assume that their results were indeed due to the state of alkalinity produced in the body. They pointed out the similarity between the conditions of alkalosis and diabetes, and suggested that the administration of large amounts of alkali to diabetics might well prove dangerous. Collip and Backus<sup>4</sup> had previously shown that severe overbreathing could produce actual hyperglycaemia. Pavy in 1861 had shown, on the other hand, that acidosis was often accompanied by glycosuria. Haldane, Wigglesworth, and Woodrow, therefore, compared the effects of acidosis produced by ammonium chloride ingestion with the effects of alkalosis previously described. They found that acidosis, like alkalosis, lowered very definitely the glucose tolerance, and that the lowering of tolerance much outlasted the acidotic state. On the other hand, they found no ketosis

and no lowering of the respiratory quotient, so that there was no sign of interference with the oxidation of carbohydrates. They therefore concluded that alkalosis checked the oxidation of carbohydrate, whereas acidosis only hindered its storage. Wigglesworth in 1924<sup>5</sup> further investigated the effect of alkali administration upon fat metabolism in rats. He showed that rats, when fed upon a diet consisting wholly of fat, developed a considerable ketosis, which, however, was transitory. By about the fifth day of feeding the rats had become acclimatized, and had no abnormal ketosis and showed no ill effects. The addition to this diet of considerable amounts of bicarbonate caused exaggerated and greatly prolonged ketosis, delaying the acclimatization almost indefinitely. It also produced ketosis in rats on a normal diet, and, as in the case of the human subjects, the "acetone body" excreted was chiefly  $\beta$ -oxybutyric acid. If large doses of bicarbonate were given to rats on a fat diet, however, greatly increased excretion of acetone and aceto-acetic acid was also demonstrated. It thus appears certain that alkali renders more difficult the oxidation of fat in the absence of sufficient carbohydrate, and a condition of alkalosis would thus aggravate one of the difficulties of the diabetic organism. Goldblatt tried the effect of administering alkali to a subject with high sugar tolerance, and found that the tolerance was lowered by the alkalosis. He found also that the ketosis and intolerance to carbohydrate produced by starvation are both definitely increased by the ingestion of alkali by the starving subject. The administration of 30 grams of bicarbonate to a case of severe glycosuria without any ketosis caused the appearance of ketone bodies in the urine. This case had been observed intermittently for twelve months previous to the experiment, and had never before shown any ketosis. Goldblatt confirmed the results of Hetenyi, which showed that the administration of alkali inhibits to a considerable extent the action of insulin. Goldblatt's work thus confirms the belief that alkalosis causes a derangement of carbohydrate metabolism. It suggests, moreover, that the storage as well as the oxidation of carbohydrate is interfered with, since he found in experiments with rats (which should perhaps be repeated on a larger number of animals) that a very considerable diminution of the amount of glycogen present in the whole carcass was produced by feeding with a diet to which alkali was added.

#### LUNACY REFORM IN FRANCE.

FRANCE bears an honoured name in lunacy reform. It was the immortal Pinel who, during the tumult of the revolution, unfettered the insane from their chains, and ushered in a new era of humanitarian progress. "Everywhere throughout Europe until 1794," said Esquirol, his pupil, "the insane were in chains. It was not thought that anything more should be done for them." Pinel's ideas, however, were inadequately realized, and although the lunacy enactments which followed his dramatic stroke were conceived with the purpose of mitigating the harshnesses and abolishing the abuses under which the insane laboured, they yet exhibited no understanding of the problem as one of medical care and treatment, but had regard only for the public safety. Such an enactment was the Act of 1838, which still regulates the procedure with regard to the certification of the insane, and is now under review by the French Government. It has frequently been assailed ever since it was placed on the Statute Book, but of recent years its critics have become more numerous and more insistent. At the request of a committee (la Commission d'Hygiène du Sénat) Dr. Toulouse, who is chief of the Henri-Rousselle Psychiatric Hospital in Paris and president of the League of Mental Hygiene, has submitted a memo-

<sup>1</sup> *Biochem. Journ.*, xxi, p. 99L.

<sup>2</sup> *Journ. Physiol.*, 54, 1920.

<sup>3</sup> *Proc. Roy. Soc.*, B, 96, 1924, p. 15.

<sup>4</sup> *Amer. Journ. Physiol.*, 61, 1920, p. 568.

<sup>5</sup> *Biochem. Journ.*, xviii, 1924, pp. 1203, 1217.

randum which, has caused widespread comment. Dr. Toulouse criticizes freely the provisions of the 1838 Act, and asserts that its spirit is inimical to the interests of the mentally affected patient. He thinks it should apply only to the relatively small number of violent and dangerous patients, and be suitably amended accordingly. For the great majority of the mentally deranged the thorough treatment required can, he maintains, be attained only by the conversion of the present asylums into hospitals. Where it is found necessary that a patient should be kept in confinement, the preliminary examination would be made elsewhere than in the infirmary, which, under the Act, is, like the asylum, a place of detention. The certificates would be signed by specially appointed alienists, who would be quite independent of the judicial authority, which would then be enabled to render the certificate operative. Dr. Toulouse advocates the provision in every region of France of centres for the prevention and early treatment of mental disorder, along the lines of the Henri-Roussello Hospital in Paris; this institution is a complete psychiatric unit with various activities. It comprises a department for the prophylaxis of mental disorder, an out-patient mental clinic where patients are examined and, if necessary, the services of other specialists utilized, a voluntary treatment centre for all kinds of mental disorder, an observation pavilion in which borderland cases are studied and where, if necessary, detention can be enforced for a week, quarters for dangerous or violent patients, laboratories, and instructional classes dealing primarily with the problems of prevention of mental disease. It will be interesting to see what action is taken in regard to these proposed amendments. It would seem that the time is ripe for a thorough revision of the lunacy laws in France, and the present attitude towards reform augurs well for the ultimate success of measures which will react beneficially on the whole life of the community.

#### SERUM TREATMENT OF POLIOMYELITIS.

THE treatment of acute anterior poliomyelitis by means of injections into the spinal canal of serum from patients who have suffered from the disease previously has not received an extended trial in this country, although the late Dr. F. E. Batten interested himself in it. Since 1910, when this procedure was suggested by A. Netter, attention was given to its possibilities by Professor G. Etienne of Naney, and on October 22nd, 1927 (p. 743), we referred at some length to the results which have been obtained. In a recent communication<sup>1</sup> to the Académie de Médecine A. Netter suggests that the reasons for the relative neglect of what is held to be a valuable therapeutic measure are an insufficient knowledge of the indications for the use of serum and an exaggeration of the difficulties of obtaining it. In consequence of the outbreaks in 1926 in Great Britain and Germany Netter has reviewed the subject, and recalls the fact that in 1910 he discovered, jointly with Levaditi, that the blood of patients who had suffered from anterior poliomyelitis contained immune bodies which rendered virulent spinal cords uninfected for monkeys. Netter places the cases for which convalescent serum is indicated in three groups—namely, those in the pre-paralytic stage, those with rapidly spreading paralysis (Landry type), and acute cases with recent paralysis which is showing no tendency to extend. In the first group, he remarks, the main difficulty lies in diagnosis, but in the presence of an epidemic this should not be impossible, and lumbar puncture gives valuable help. In one series of cases in America seven patients were treated within the first twenty-four hours of onset by intramuscular injections of serum, with rapid recovery in each instance. Of the acute spreading variety, the ascending type of Landry, Netter records his

personal experience of two cases where the prompt injection of convalescent serum not only prevented further paralysis, but brought about in one the complete disappearance of a paraplegia with retention of urine. When paralysis is already established the beneficial results of serum treatment depend largely upon how soon it is employed. Netter believes that it is of little efficacy after the fourth day, and still less at the end of a week, although reports from South America seem to indicate that small doses may still do good as late as the twelfth day after onset. The dose of serum employed by Netter varies with the age of the patient, the gravity of the symptoms, and the duration since the onset. He usually administers 10 to 30 c.cm. intrathecally, although in one case he gave as much as 66 c.cm. in ten injections. He adds that the difficulty of obtaining the serum of patients who have suffered from the disease has been largely overcome by keeping a record of old patients so as to make use of them when an epidemic commences. This was accomplished in 1925 in Melbourne, where 110 patients who had previously had the disease were quickly obtained as donors by the help of official registers, hospitals, doctors, masseurs, and even orthopaedic instrument makers. The serum so obtained can apparently be stored for short periods in ampoules. The serum of immunized horses has also been efficacious in certain cases, but its supply at the present time is limited.

#### THE PREVENTION OF INDUSTRIAL INVALIDITY.

THE Council of Industrial Medicine called a number of representatives of industry into conference in London on March 2nd, at the house of the Federation of Medical and Allied Services, with a view to discussing schemes for the prevention or amelioration of industrial invalidity. Dr. D. A. Coles, the chairman of the council, who presided, referred to the millions of weeks wasted annually by disablement or illness. A skilfully devised scheme whereby this invalidity could be prevented or more expeditiously treated would, he said, cast no additional burden upon industry, but, on the contrary, would relieve it of a part of the burden it already carried. In a plea for works clinics Professor E. L. Collis pointed out that the treatment of industrial injury included wound healing and restoration of function, and, while every surgeon was concerned with wound healing, it needed some special acquaintance with industrial medicine, and in particular with the occupation to which the injured person was returning, to bring about restoration of function in the best way. He urged that the setting up of industrial clinics would vastly reduce compensation claims. Dr. Alfred Salter, M.P., as a medical officer of three large trade unions, referred to the acute difficulty of men employed on the industrial fringe of London in obtaining suitable after-treatment in cases where traumatic arthritis had developed. They could get such treatment only by travelling to a central London hospital, which often they were not able to do. He said that if only after-treatment were available very many of these cases, which now dragged on for months, would be restored to full functional activity after a few weeks. Some account was given of an industrial clinic by Mr. Maurice Salmon, of the Lyons catering firm, who said that in trying to deal with the slighter kinds of accidents on the premises, rather than send them out to the hospitals or insurance practitioners, his firm had felt that they were saving themselves a great deal of lost working time and their employees a great deal of suffering. Dr. Howard Mummery, director of the Lyons clinic, said that during the past three months 2,909 new injuries of all kinds had been treated in his clinic, and in 2,730 of these cases the patients had remained at work; thus in only 6 per cent. was there any lost time involved. The number of redressings during that period was 5,060, of which 4,716 were

<sup>1</sup> Bull. de l'Acad. de Méd., xlix, January 31st, 1928, p. 141.

done during employment without loss of time. The treatment and dressings were given by hospital-trained nurses under close medical supervision, and the average time was ten minutes to each case. So far as first aid is concerned, the railways were highly commended. Sir Percy Wilkinson, secretary-general of the Order of St. John of Jerusalem, said that over 40,000 railway employees had been trained to deal with accidents, and Dr. W. Salisbury Sharpe, chief consulting surgeon to the Great Western Railway, spoke of the very large number of men on that railway who not only had had training in first aid, but who kept up their training by passing through a course every year. Dr. Drummond Shiels, M.P., as one who had a great deal to do with railway workers, said how much he was impressed by the skill shown by numbers of them at various points in the railway system in dealing with the accidents which occurred to their fellows in the course of their employment. Mr. Henry Lesser mentioned one interesting experiment in progress at a gas works, where, after any serious injury, a jury of workmen was called together—the members of the jury having had experience of the work on which the injured man was employed—and the official responsible at the particular depot or station where the accident had occurred presided. Witnesses were summoned, including, if possible, the injured man himself, and the jury decided whether there was any fault, and, if so, where it lay, and made suggestions as to prevention. Dr. Fortescue Fox, Dr. M. B. Ray, and other speakers mentioned the movement for the establishment of clinics dealing with rheumatism, in particular the venture in London sponsored by the British Red Cross Society. The large number of cases of so-called rheumatism which were not suitable for the hospitals, and for which there was at present no provision, accounted for a vast sum of industrial invalidity. A resolution from the chair was carried approving, in general, co-operation between industry and medicine, and pledging those present to support schemes tending in that direction. It will now be for the Council of Industrial Medicine, in the light of the expressions of opinion at the conference, to suggest some practical proposals. Employees of labour are to be asked what steps the council can take to help them.

#### PULMONARY ACTINOMYCOSIS.

INFECTION with the ray fungus, the causal organism of actinomycosis, is said to be fairly frequent in certain parts of the world, such as Germany, Russia, and Austria. In England and America, though isolated cases are reported from time to time, the disease would appear to be a comparatively rare one in man. Infection is usually found to occur in those whose occupation entails the handling of straw and grain and by those in close contact with vegetable products. It is through the alimentary or respiratory tracts that infection most commonly occurs, and statistical considerations indicate that the infection is primarily a pulmonary one in from 15 to 18 per cent. of the recorded cases. The symptoms produced in the lungs closely resemble those of tuberculosis, and this diagnosis will usually be made, provided the continued absence of tubercle bacilli in the sputum is ignored. This lesson is well brought home by a case reported by Dr. F. M. Johns.<sup>1</sup> This patient had been regarded as tuberculous for twelve years, and during that time this diagnosis was confirmed by numerous x-ray and sputum examinations, in which tubercle bacilli, however, were never found. Expectoration had always been profuse, containing numerous large granules which the patient himself, being a mechanic, had found to measure up to three-sixteenths of an inch. These granules, when compressed under a cover-glass and examined microscopically, presented the characteristic

appearance of actinomycotic granules. Cultured on glucoso agar the organism had grown into long filamentous forms, which were partially acid-fast. Both the granules in the sputum and the cultures were not pathogenic for guinea-pigs. A month's treatment with rather large doses of iodides has resulted in an encouraging reduction in the amount of the sputum.

#### THE CORONARY CIRCULATION.

THE physiology of the blood supply to the heart has hitherto been very much a matter for conjecture. That this should be so, and that experimental work on the subject has given somewhat conflicting results, is little to be wondered at if the difficulties of such investigations are appreciated. It is, however, becoming more and more obvious that better and fuller knowledge of this branch of physiology is essential in view of the rapid advances that have of recent years been made in the study of coronary disease. Few of those interested in current medical thought and work can have failed to notice frequent references to the comparatively newly recognized syndrome of coronary infarction. The pathological entity has long been appreciated, but that the condition is now clinically separable from the great group of angina pectoris is shown by several recent publications, notably that by Parkinson and Bedford,<sup>2</sup> who analyse 100 cases, most of them correlated with post-mortem findings. Clearly, in the present state of our knowledge, research into the vascular supply of the heart must be by animal experiment. This line has been followed in the past principally by Rebatel in his investigations on the horse, by Porter, and by Langendorff, but the value of their work has been called in question by succeeding investigators on account of the inadequacy of their recording systems, or the artificial conditions under which their experiments were conducted. These earlier attempts at elucidating the problem are reviewed by Anrep, Cruickshank, Downing, and Rau<sup>3</sup> in their recent work on the coronary circulation in relation to the cardiac cycle. For their experiments they employ the denervated heart-lung preparation of the dog, and the coronary inflow and outflow are recorded electrically, both separately and together, and are further correlated with the electro-cardiogram and with curves of intracardiac pressure. These observers find that the curve representing coronary outflow shows three waves, the first closely following auricular systole, the second at the beginning of ventricular systole, and the third during the ejection phase of ventricular contraction. The last wave is by far the largest, showing that the contraction of the heart is the principal factor in promoting coronary outflow. It might be argued that this increased outflow was the result of systolic increase in the aortic pressure, but this is disproved by taking a curve of coronary inflow, which is found to be restricted during the ejection phase of ventricular systole. Analysis of coronary inflow gives evidence that blood flows into these vessels during ventricular diastole. Auricular contraction does not influence inflow, but contraction of the ventricle impedes the passage of blood into the vessels, this hindrance reaching its maximum at the conclusion of ventricular systole, and presumably being due to compression of the coronary arterioles by the heart muscle. In these important results there is provided at last a clear and precise picture of the vascular supply of the heart, and it is necessary to consider how these findings widen our conception of coronary disease and whether they are of assistance in determining treatment in myocardial infarction. Coronary thrombosis is attended by two dangerous possibilities. The first is that extensive necrosis may be followed by cardiac failure; the second is that as a result of high blood pressure haemorrhage and extension of the morbid process

<sup>1</sup> *The Medical Clinics of North America* for November, 1927.

<sup>2</sup> *Cardiac Infarction and Coronary Thrombosis*, *Lancet*, 1928, i, 4.  
<sup>3</sup> *Heart*, 1927, xiv, 111.

may occur. Treatment in the first event must be directed toward the maintenance of adequate blood flow through the coronary vessels, so that nutrition may be encouraged and the damage reduced to a minimum; just as we employ stimulants with this aim in cerebral thrombosis, so we should expect them to exert a beneficial influence in obstruction of the coronary circulation. On the other hand, in order to avert the possibility of further damage, reduction of blood pressure should be the aim. Only by careful consideration of the individual case can it be decided which of these courses should be followed. Past or present evidence of high blood pressure in a patient suggests measures for the prevention of a return to the habitual pressure level following the fall in arterial tension which is nearly always a sequel of myocardial infarction. In view of the fact that systole occupies a constant time whatever the heart rate, it is clear that with increased rate of beat there is in a given period less aggregate time for coronary inflow than with slower rates; with the aim of slowing the heart and so providing better blood supply to this organ Parkinson and Bedford recommend the use of digitalis in cardiac infarction, especially where rapidity of the heart's action is the result of fibrillation or other abnormal rhythm, and where failure is present or appearing. The tendency for digitalis to raise the blood pressure should contraindicate its administration in coronary thrombosis when there is evidence of hypertension and when the normal cardiac rhythm is preserved.

SIR HUMPHRY ROLLESTON will give the William Sidney Thayer and Susan Read Thayer Lectures on Clinical Medicine on March 20th and 21st at the Johns Hopkins University, Baltimore.

Dr. T. Izod BENNETT will deliver the Goulstonian Lectures before the Royal College of Physicians of London on March 13th, 15th, and 20th, at 5 p.m., at the College, Pall Mall East, S.W.1. His subject is "Some problems of nephritis." Any member of the medical profession will be admitted on presentation of card.

As we announced last week, the Sir Charles Hastings Popular Lecture for this year will be given by Sir George Newman, Chief Medical Officer to the Ministry of Health, whose subject will be "The fundamentals of health." The lecture will be delivered in the Great Hall of the British Medical Association's House in London on the evening of Wednesday, March 21st, when the chair will be taken at 8 p.m. by Lord Cozens-Hardy. Admission is free, by tickets obtainable from the Financial Secretary, B.M.A. House, Tavistock Square, W.C.1. Seats not occupied by 7.50 p.m. by ticket holders will be available for other members of the public.

Dr. E. GRAHAM LITTLE, M.P., will give an address on the future of medical practice—intended more especially for senior students and young practitioners—at a meeting arranged by the Metropolitan Counties Branch of the British Medical Association, to be held at the B.M.A. House, Tavistock Square, London, on Thursday, March 22nd, at 5.30 p.m. Tea and coffee will be served at 5 o'clock. All fourth and fifth year medical students and recently qualified practitioners are cordially invited.

We regret to announce the death on March 3rd of Dr. James Wbeatley, county medical officer of health for Shropshire, and president of the Society of Medical Officers of Health.

## Nova et Vetera.

### A MEDICAL LITERARY CLUB.

THE doctor who devotes all his time and energy to the practice of medicine, without any outside interest, may be a very successful practitioner, but he must lead a routine life. Incessant concentration of thought on one subject promotes a narrow outlook on life, limits his point of view, and hastens his degeneration into a mere machine. While some form of sport provides the youthful members of the profession with much-needed relaxation, many of middle age interest themselves in local government, and do useful work for the community as councillors, aldermen, or mayors. There have been exhibitions of the works of medical artists. A minority, perhaps, find distraction from the *sturm und drang* of medical practice in the cultivation of the literature of their own and other countries. After the daily round, the common task, these men find pleasure in some intercourse with the great minds of all ages. "Let me have books," said Horace, "and a contented mind."

Sit bona librorum et provisae frugis in annum,  
Copia, neu fluitem dubiae spe pendulus borae,  
Sed satis est orare Jovem quae donat et aufert;  
Det vitam, det opes, aequum mi animum ipse parabo.

*Epistles, I, 18.*

A few doctors, filled with these desires and the ambition to attain Horace's degree of contentment, founded a literary club in Newport (Mon.) some twenty years ago. Now since it has run its course and ceased to be, perhaps the brief account of it which follows may lay the foundation on which similar structures may be raised. Its proceedings were never chronicled in lay or medical papers, publicity was not one of its objects, and this *post-mortem* report is its only introduction to the medical world.

Now as to its pre-natal conditions and the manner of its birth. All potential medical members were approached, the scheme was explained, and, their consent obtained, a preliminary meeting was held at which a code of rules was drawn up and adopted. As the members numbered ten the club was called "The X Club."

A meeting was held once a month from October to June at each member's house in rotation; the host of the evening was chairman. Members might be fined for absence without sufficient cause and for ignorance of the subject under discussion. At each meeting the subject for the following one was chosen, and it was the duty of every member to procure and read books dealing with the matter. The chairman for the evening opened the discussion with either (a) a written paper or (b) a verbal discourse, and at its conclusion called on each member in turn to supplement this with further matter relevant to the subject. He might provide light refreshments. Minutes were kept. The club displayed great catholicity in its choice of subjects. Ruskin's "Stones of Venice," Carlyle's "French Revolution," Boswell's "Johnson," Keith's "Antiquity of Man," eugenics, Prescott's "Conquest of Peru," the dole in ancient Rome, glaciers, "Pepys's Diary," and many others appear in the minute book. Much has happened since Norman Angell's book "The Great Illusion" was written. It provided the club with a subject.

During the summer one day was devoted to a visit to some place of interest—a cathedral, an abbey, or one of the numerous Norman castles along the Welsh border. The club continued its activities during the war, as all its members were over military age and were employed at home. Its monthly meeting was a welcome diversion from the work and anxiety inseparable from the world conflict.

The club achieved its objects. Members were faithful, the club's monthly meeting was eagerly anticipated, and penalties were seldom inflicted for any breach of the rules. The reading habit was encouraged among its members, and they gained that *aequum animum* alluded to above.

The manner of its exit? No, it did not meet a violent end like that other society ever famous in the course of Bret Harte. It died of asthenia. Three of its members predeceased it, another left the district, a fifth was in feeble health and unable to attend. The time of its passing had arrived, and the survivors, with much regret, sounded a coronach and celebrated its obsequies.

A. HAMILTON, B.A., M.D.

## Ireland.

### The Samaritan Hospital, Belfast.

THE LAY MAYORESS presided at the annual meeting of the Samaritan Hospital, Belfast, in the City Hall, on February 29th. The annual report stated that the extension of the buildings was commenced in August, 1926, and that the new building would be ready for occupation on May 6th. The senate of the Queen's University had made available, meanwhile, temporary accommodation. One new ward would be named after Viscountess Craigavon, and another the Florence Henderson ward, in grateful recognition of the efforts of these two ladies to raise funds. The ceremony of laying the foundation stone had been performed by Lady Craigavon on December 5th, 1927. The new operating theatre would be named after the Northern branch of the Irish Rugby Football Union, from whom the building fund had received help amounting to £1,000 in the last few years. The medical report showed that 339 patients had been admitted to the wards during the last year, and that 331 operations had been performed, of which 128 were major ones. In the out-patient department 646 patients were treated. The Right Hon. H. M. Pollock, D.L., M.P., Minister of Finance, moving the adoption of the annual report, drew attention to the fact that this hospital received patients from all Northern Ireland, and even beyond its boundaries; no charge was made unless the patient could pay. He emphasized the consensus of opinion favouring the present voluntary system of hospitals. The Lord Bishop, the Right Rev. Dr. Grierson, proposing a vote of thanks to the surgical staff, referred to the loss the hospital had sustained by the resignation of its senior surgeon, Mr. John Campbell.

### Appointment of New Medical Officer for Belfast.

At the monthly meeting of the Belfast Corporation on March 1st it was decided to advertise for a medical superintendent officer of health at a salary of £2,000 a year, and for a city surveyor and engineer at a similar salary. These appointments are to fill the vacancies caused by the resignations of Dr. H. W. Bailie and of Mr. E. S. Pinkerton. Alderman Dr. Williamson, who moved the adoption of the minutes of the Public Health Committee, said that the committee and corporation were determined to appoint candidates of ability and public health experience so that Belfast should no longer lag behind in matters of public health. The duties had been increased; the Ministry of Home Affairs had asked them to take over all public health services. The man to be appointed must have had not less than ten years' experience in public health work. A special resolution granted a retiring allowance of £906 a year to Dr. Bailie.

### Public Health Works for Relief of Unemployment.

The committee appointed by the Free State Government to consider and report as to the steps that might be taken for the immediate relief of unemployment has included in its recommendations the undertaking of public health developments such as waterworks, sewerage schemes, improvement of burial grounds, provision of fair and market greens, and works of construction in connexion with county homes, county hospitals, mental hospitals, and sanatoriums. Housing, which is a work of public health, has already been dealt with in this connexion. The committee is satisfied that much work has yet to be done before the position of the Saorstát in the important matter of public health services is satisfactory or equivalent to that of other countries. It is common knowledge that in many parts of the country water supply and sewerage conditions are deplorable, and the committee indicates in an appendix to the report the various towns and villages in the Saorstát which are at present without modern or up-to-date waterworks or sewerage systems. At the same time, the committee feels that the Government is to be congratulated upon the steps which have been taken to secure improved conditions in this respect. Since the beginning of the great war financial advances for this purpose ceased to be obtainable, and the banks were reluctant to lend for

any extended period. The action of the Government, however, in providing, in the Local Loans Fund, since 1925 for loans to local authorities for works of this nature has proved most beneficial, and many necessary schemes have been sanctioned. The committee would, however, like to see these loans made use of by local authorities to a very much greater extent than has been the case up to the present. The committee believes that the appointment of county medical officers of health, whose duty it will be to educate public opinion in the matter of public health and to ensure that the chronically bad conditions of the various towns and villages throughout the whole country are speedily remedied, will result in a steady improvement; it is added that no time should be lost in the appointment of these officers. A difficulty which, the committee understands, is holding up many urgently needed public health schemes is that of cost. The ratepayers who are to benefit immediately are often unable to bear the whole of the increased rate represented by the loan charge, and there is disinclination on the part of ratepayers in contiguous areas to shoulder any part of the burden. While it may not be unnatural for a ratepayer or taxpayer to hold that he should not be obliged to pay for a service which he does not receive, the committee considers that this difficulty would speedily be removed if he could be made to see that he is, in fact, paying in other ways a great deal more; by reason of the absence of proper public health systems of the kind. The committee considers that this aspect of the case should be brought to the notice of the local authorities and the general public; if the problem of public health were approached in this way, and a suitably graduated system of charge could be devised, the question of the area of charge would no longer be a bar to the progress of such schemes. It will be obvious, the committee concludes, that the more of these schemes that are put in hand the greater will be the relief of unemployment, and that the removal of any difficulties in the way of carrying out such works must necessarily result in increased employment.

### Milk Contractor Heavily Fined.

At Enniscorthy District Court the contractor for the supply of milk to the County Home was prosecuted under the Food and Drugs Act in respect of milk supplied for consumption to the inmates. Having heard the evidence, the judge said the circumstances surrounding the case made it the worst of its kind he had yet met with. He was entitled, where there was a second conviction, to send the defendant to prison for three months, and but for the defendant's physical condition he would not hesitate about awarding this penalty. The maternity home for the county had at least a hundred infants in it, and had been receiving this inferior quality of milk. He inflicted a fine of £20, with the analyst's fee, 10s. 6d., and £2 2s. costs. The defendant would be allowed ten days in which to pay, or, in default, would be imprisoned for four months.

## Scotland.

### Morningside Annual Report.

THE 115th annual report of the Royal Edinburgh Hospital, Morningside, records yet a further advance in the campaign directed towards the hospitalization of the epileptic so assiduously waged by the physician-supervisors, Professor G. M. Robertson. The Royal Asylum, which has been given to an Act by which the title "The Royal Edinburgh Hospital for Mental and Nervous Disorders" has been substituted for that of "The Royal Edinburgh Asylum for the Insane." The new designation is appropriate, and justly reflects the gradual alteration in the character of this hospital and the increasingly enlightened attitude of the public towards mental disease. Professor Robertson states that twenty years ago 317 persons were admitted to this institution, of whom only 2 per cent. were voluntary patients, while last year there were 239 admissions, of which 62 per cent. were voluntary. An institution to which nearly two-thirds of those admitted come voluntarily can no longer be truly described as a

place of detention. Professor Robertson sums up his experience of the benefits of voluntary treatment as follows:

"We find that voluntary patients are admitted for treatment sooner than certified patients, that they come when their malady is more recent and less serious, that they are more contented to be treated, that their residence in the hospital is shorter, and that a larger proportion of them recover, though many leave before they are quite recovered. They leave when they feel themselves improving, and some, no doubt, complete their recoveries at home. More than one-half have been ill for less than three months before coming for treatment, and more than one-half who come suffer from melancholia. In these cases voluntary treatment leads to earlier recovery and the prevention of many suicides."

With regard to the certified patients two features in the statistics call for notice. The first is the small number of admissions compared with the large resident population—the legacy of the past. Of 812 certified patients treated during the year only one-ninth were new admissions. In the second place, the number of removals by discharge and death exceeds the number of admissions, so that the certified population in the Royal Hospital is diminishing, and in the course of a decade may shrink to a half of what it is at present. Professor Robertson suggests that the form of official statistics should be recast with a view to recognizing these changes. In addition to the two departments of the Royal Edinburgh Hospital, Craig House and The West House, there are, under the same management, six nursing homes to which patients may be admitted in exactly the same way as they would be to ordinary nursing homes; in this respect these are unique medical institutions. Most patients admitted to these nursing homes have come for the treatment of functional systems, including states of neurasthenia, depression, anxiety, sleeplessness, and nervous exhaustion. Work is proceeding in connexion with the completion of the Jordanburn Hospital, which was designed for the treatment of cases of nervous and of early mental disorder. Accommodation will be provided for the psychiatric and psycho-pathological investigations required by the public authorities of the city, its schools, and police courts, and by social agencies in and about Edinburgh, as well as for a free mental out-patient clinic. The building is to include a lecture theatre for the benefit of students attending the class of psychiatry. The weekly out-patient mental clinic is being held at present at the Royal Infirmary. Professor Robertson foresees remarkable developments in the psychiatric world, and compares the new psychiatric crusade with the successful campaign against tuberculosis started in Edinburgh under the auspices of Sir Robert Philip. "Forty years ago patients were sent to hospitals with cavities in their lungs and in the last stages of the disease. Arrangements were therefore made to discover the disease at an earlier and more hopeful stage; out-patient clinics and dispensaries were instituted; finally, the family and the home came under review for early and preventive treatment." Psychiatrists, Professor Robertson adds, must do likewise. Referring to the report of the recent Royal Commission on Lunacy, Professor Robertson expresses his fear that the new legislation in England will, in some important matters, be on lines seventy years behind Scottish procedure. In Scotland no layman ever sees a patient to decide whether he should be treated in a mental hospital or not. "The responsibility of dealing with a difficult medical problem has been wisely left in the hands of the medical profession. This trust has not been misplaced, the public has not been let down, for there is no record in our law courts during the last seventy years of anyone being improperly detained in a mental hospital."

#### Glasgow Western Infirmary.

The fifty-third annual meeting of the Western Infirmary of Glasgow was held on February 17th. Lord Provost Sir David Mason, who presided, said that an important feature of the report was that this infirmary was in a most satisfactory position from a financial point of view. The ordinary revenue was greater by nearly £3,000 than that of last year, while the ordinary expenditure had decreased by nearly £2,000. Mr. John C. Roxburgh, chairman of the board of managers, pointed out that although there was a deficit as regarded ordinary income and expenditure

of £10,042, this was the smallest during the last ten years, except for the exceptional year of 1925, when it was about £7,000. As showing the rise in cost of running the infirmary, he mentioned that in 1924 the expenditure had been £44,152, while in 1927 it had been £82,375. Workmen's contributions, which had been recently depressed, were now again on the up grade, and the speaker referred to the collections by students, which had already endowed three beds in the hospital at a cost of £1,500 each. The important feature of the year had been the opening of the David Elder Infirmary at Govan, which was to be carried on as an annex of the Western Infirmary, and was already making its influence felt on the waiting list. The annual appeal for increased funds must be renewed, but the managers were especially anxious to obtain money to erect a new x-ray and electrical department, as the present department had been built twenty years ago in the early days of x-ray development, and now proved inadequate to the amount of work which had to be done. For this purpose the managers had in hand a sum of £5,800, but at least £20,000 would be required before they could feel justified in beginning the new building.

#### Craigleith Hospital.

Some discussion has taken place in regard to the proposed closing of Craigleith poorhouse, which has been used as a Ministry of Pensions hospital since the war, and during the war was in use as a military hospital. A letter was read by Sir Samuel Chapman at the annual dinner of the Edinburgh Parish Council and District Board of Control which he had received from the Minister of Pensions. The letter made it clear that it is not the intention of the Ministry of Pensions to remove all pensioners in Scottish hospitals to England, as had been rumoured. The natural decline in the volume of medical work in respect of pensioners in Scotland had made it necessary to revise the arrangements for their treatment, and as the number of pensioner patients now under treatment is about 100, with a tendency to grow less, it appears unreasonable that a hospital accommodating 520 beds should be maintained for the small number requiring treatment. The alternative accommodation, to which it is proposed to remove the pensioner patients, is Edenhall Hospital, which was built, equipped, and placed at the disposal of the Government by the Scottish Red Cross during the war. As this affords sufficient accommodation, it is proposed by the Ministry of Pensions to utilize it for their future requirements and to hand back the building at Craigleith to the parish council.

#### Poisoning from Furs.

At a meeting of the North British Branch of the Pharmaceutical Society of Great Britain at Edinburgh on February 29th Mr. J. Wilson Dougal, B.Sc., read a communication upon dermatitis caused by wearing furs. The lecturer had found that in some cases where dermatitis had been caused an infusion made from the fur worn was poisonous to tadpoles, while antimony could be detected by careful analysis, suggesting that tartar emetic had been used as a mordant in dyeing the fur. The toxic action of tartar emetic was evident even in so dilute a solution as 1 in 50,000. Cases of such dermatitis had not been so frequent of late, since dealers in furs had, to a large extent, given up employing tartar emetic as a mordant. Dr. E. G. Bryant read a paper on recent work on the glucosides, in which he discussed the formation of glucosides in plant metabolism. He said that vitamin D, which was of great importance in animal nutrition, could be formed by the action of ultra-violet rays on the glucoside ergosterol. Mr. William H. Millar read a note on arsenious oxide in neutral and alkaline solution, dealing with the arsenical solutions used in medicine. There were objections to Fowler's solution of arsenic because it was unstable and incompatible with medicines containing alkaloids. He had found that a satisfactory 1 per cent. neutral solution of arsenious oxide could be prepared by using just sufficient potassium carbonate to dissolve it, and neutralizing the solution with sulphuric acid.

## Leith Hospital Report.

The annual meeting of contributors to Leith Hospital was held on February 24th under the chairmanship of Mr. John A. Lindsay, D.L., president of the Board of Management. It was stated that the total number of patients treated in the wards and out-patient department during the year had numbered 19,305, of whom 1,003 had been dealt with in the new children's wing. The ordinary income had amounted to £16,349 and the ordinary expenditure to £16,834. The extraordinary income had amounted to £28,067, while the extraordinary expenditure had been only £4,913. The chairman said that contributions by the employees in the various workshops had risen from £1,692 to £2,037 in the past year, which was particularly gratifying. He also intimated that the Leith Provident Co-operative Society had decided to give a sum of £1,750 to endow a bed in the hospital.

## Presentation to Dr. T. A. Sellar.

Dr. Thomas Sellar of Aberlour, Speyside, was presented on February 25th with a Morris-Oxford motor car and a portrait of himself, on the occasion of his retirement after forty-four years of medical practice in the locality. The Provost, Canon Jenks, referred to the great services rendered by Dr. Sellar to all classes throughout his wide district, and mentioned the leading part he had taken in the various social activities of the community. Dr. Sellar, replying, said that he proposed to continue to live in the neighbourhood, and gave an account of the many changes he had noted during his residence there. With very few exceptions every house and farm in the various parishes and villages had changed hands. When he began practice his visits were paid on foot, on horseback, or in a gig. After a few years the introduction of the bicycle enabled him to reach his patients much more quickly, and, when the motor car became available, it materially shortened the time taken by his long rounds. Dr. Sellar commented on the longevity of the local inhabitants, and quoted a curious case of twin birth: one twin had been born on one day and the second not only on the following day, but in the next year and the next century.

## England and Wales.

## Bridewell and Bethlem Royal Hospitals.

THE LORD MAYOR OF LONDON presided at a court of governors of the Royal Hospitals of Bridewell and Bethlem, held at Bridewell Hospital on February 27th, in support of an appeal for £120,000 required for the erection of the new Bethlem Hospital buildings at Monks Orchard, Shirley, Surrey. He announced that the president, Sir Charles Wakefield, Bt., had given £25,000 to defray the cost of the science and treatment unit and the chapel, and that Lady Cooper had presented £5,000 for the main recreation hall, in memory of her late husband. Other donations reported included an anonymous gift of £5,000, and one of 1,000 guineas from the treasurer, Sir Lionel Faudel-Phillips, Bt. The Lord Mayor commented on the scheme of building the new hospital which had been adopted by the governors, and referred to the great interest in it of the Corporation of London. Bethlem Royal Hospital, an ancient foundation of the City of London for the treatment of mental and nervous disorders, traces its origin to the year 1247, and some reference to its history since that date was made in our columns on May 7th, 1927 (p. 849). The present buildings in the Lambeth Road, Southwark, opened in 1815, are quite unsuitable now, more space for special treatment and accommodation for the medical and nursing staff being urgently required. On the new site detached buildings will permit better classification of the patients, with pathological, bacteriological, psychological, dental, electrical, and radiological departments; fuller facilities for research will also be available. The governing body of the hospitals is now appealing for a sum of about £120,000, which will enable the new buildings to be opened without debt, and permit the continuance of the present charitable basis, 75 per cent. of the total cost of treatment

and maintenance of patients being provided from the hospital funds. No previous appeal on behalf of the hospital has been made within living memory, and if this sum is obtained it is stated that no further appeal to the present generation should occur. Contributions may be sent to the Lord Mayor at the Mansion House, or to the president, or the treasurer, at Bethlem Royal Hospital Office, New Bridge Street, E.C.4.

## Report of Committee on London Floods.

The report of the Committee on Thames Floods, which may be obtained from H.M. Stationary Office, Adastral House, W.C.2, price 6d., is remarkable, not for its conclusions, but for the evident lack of scientific knowledge which the members encountered in their search for light on the problem. Measures have already been taken to ensure the establishment of a system of warnings, while the committee, in recommending that the statutory duty of supervising and inspecting floods defences should be definitely placed upon the London County Council within the county area, is, in effect, seconding a resolution of that body, whose position was explained in a report of the proceedings of the conference of local authorities which appeared on page 112 in our issue of January 21st. Having carried the investigation to this point the committee suggests that an intensive study of the whole subject of tides in the Thames should be undertaken by the Liverpool Tidal Institute in co-operation with the hydrographic department of the Admiralty and the Meteorological Office. It is further suggested that when the results of this investigation are available they should be applied to conditions in the upper part of the river, and that efforts should meantime be made to obtain more exact information of the part played by land floods in producing high waters. The committee's references to the unsatisfactory housing conditions brought to light by the disastrous events of January are of some interest. Many thousands of persons, it is stated, now live in dwellings in low-lying areas near the river, much below high-water level. It is regarded as impracticable to propose their displacement, but it is recommended that the London County Council should try to obtain power to prohibit, on land within possible flood limits, the erection of new dwellings or the re-erection of existing dwellings the floors of which are not up to a specified minimum level. A measure of this kind, the committee holds, would facilitate drainage, and appears to be commendable on grounds of health. The use of basement rooms as sleeping quarters was given special consideration, emphasis being laid upon the relation of this question to the general housing problem and upon the desirability of enforcing, wherever possible, the existing statutory provisions relating to such dwellings.

## Alcohol in Relation to Business Life.

An address on the relation of alcohol to business life was given by Sir Maurice Craig at the Mansion House, London, on March 1st; Sir Thomas Barlow, F.R.S., president of the National Temperance League, occupied the chair. Sir Maurice Craig said that medical science was tending more and more to the prevention of disease, and people were being encouraged to acquire some knowledge of their bodies and their mental reactions. After fifteen years in mental hospitals he had come to the conclusion that at least half of those who broke down need not have done so, and for over twenty years his work had been increasingly the teaching of persons to understand themselves and to get the best out of their mental activities. A person endowed with a highly sensitive nervous system must understand how to use it, and what external or internal stresses might affect or injure it. The minor mental disturbances were important, not only because of their manifestations, but because of the way they might develop if uncorrected. It was generally agreed that alcohol was a sedative in action and not a stimulant as had been supposed. Its effect on conduct led sometimes to the idea that it was stimulating, but the behaviour resulted from lessened control. Alcohol inhibited the control of the nervous system, diminished the power of thought, and affected judgement and accurate thinking; unfortunately the drinker was often quite unconscious that it was having

this effect upon him. One of the greatest dangers of alcohol was its power of bestowing a transitory feeling of well-being; yet it might be lessening the mental values and reducing the resistance to disease. Drug addiction was treated very seriously, though rare in this country, and yet little was done comparatively to control alcoholism, which was infinitely more common. The stresses of modern life, Sir Maurice continued, were many and severe, and no men had a greater share of them than those who worked amid the industrial difficulties and financial strain of our great cities. Therefore they must preserve their health in every way in their power. He advised them to watch their sleep, as this was the only thing that repaired fatigued tissue, but never to rely upon alcohol to get sleep. It was the worst form of sedative, for the dose required to be constantly increased. In the case of some persons it might overcome the early difficulties of defective sleep, but in the end not only failed to produce it, but aggravated the condition by bringing in other symptoms.

#### The Working of Tuberculosis Schemes.

It was reported to the London County Council on February 21st that the Minister of Health was unable to see his way to accede to a resolution supported by the council calling for the setting up of a departmental committee to inquire into the working of tuberculosis schemes throughout the country. The Minister stated that some of the matters in connexion with the treatment of tuberculosis which the council thought might be the subject of inquiry were scarcely appropriate for investigation by a departmental committee, and that if inquiry was needed on the point it should be undertaken by a medical committee. With regard to institutional accommodation for advanced cases and the appropriate duration of treatment for intermediate cases, the Minister stated that his views had already been given in circulars issued by his department, while as to the after-care and employment of tuberculous persons he was now in a position to encourage the provision of further workshops on an experimental basis in two or three large towns. He thought that any inquiry on the subject might be deferred until the result of these experiments was seen, and until further experience was available with regard to the village settlements and workshops already established.

## Correspondence.

### TETRA-ETHYL LEAD IN PETROL.

SIR,—Although no one here can pretend to expert knowledge of lead-petrol, yet I submit that we already know enough to condemn it provisionally on these three grounds:

- (1) That it can produce death or severe or mild poisoning.
- (2) That mild poisoning among the public will be unrecognizable by doctors.
- (3) That its motoring advantages can be attained otherwise and are incommensurate with the health risks. Aeroplanes may be in a different category; I do not know.

*Point (1).*—This is beyond dispute. Tetra-ethyl lead can be absorbed by the mouth, lungs, or skin. Although diluted 1 in 1,300 with petrol, the latter evaporates quickly, leaving a film of highly toxic tetra-ethyl lead for absorption through the skin. If this lead-petrol is let loose on the public, women will use it—innocently and dangerously—for cleaning purposes, in spite of warnings.

*Point (2).*—This is my chief point. Poisoning by tetra-ethyl lead is not branded by the old hall-marks on which a doctor relies to diagnose lead poisoning. Colic, blue line in gums, and wrist-drop do not occur. The symptoms are: "Drop of blood pressure, drop of body temperature, reduced pulse, sleeplessness, loss of weight, sometimes nausea, sometimes tremor, and, in most serious cases, delirium tremens. The first three symptoms are warnings, but are not serious."

<sup>1</sup> T. Midgley, *Industrial and Engineering Chemistry*, August, 1925, p. 827.

Now these acute symptoms may be enough to warn a vigilant works doctor in a tetra-ethyl lead factory; but I submit that mild poisoning, acute or chronic, of the ordinary citizen by tetra-ethyl lead cannot be diagnosed by a doctor. That, in my opinion, is the danger and treachery of this stuff.

The careful expert investigation and report to the American Surgeon-General (January, 1926), with faecal analyses and blood-stippling tests, discovered "no good grounds for prohibiting the use of ethyl-gasoline"; but the investigators go on to say that further experiments and larger experience may lead to recognizable lead poisoning or chronic degenerative diseases. Actually they did find slightly increased storage of lead in the employees of garages, etc., where lead-petrol was used.

Mr. Pryce-Jones kindly tested lead-petrol with sulphuretted hydrogen for mo: no black sulphide was produced. Doubtless this is why no blue line is found in the gums with this non-ionized compound.

The Government proposes to appoint a strong committee to investigate lead-petrol, and meanwhile to permit its use. Surely this is the wrong order. A poison should be investigated before being let loose on the public. And the committee will take a year at least to report adequately; the American report took seven months, and found it too short a time.

Another fallacy is that the problem can be solved by chemical and medical investigation. I feel convinced that this is impossible in regard to slight or chronic poisoning effects. No investigators can report whether slow slight deterioration of arterioles or of nervous tissues occurs in the course of years in human beings. That is the main danger to the public, and, speaking medically, I would say it is certain to occur to some unknown extent. Urbanization and civilization already have sufficient drawbacks to health—for example, the smoke pall—without stupidly allowing another unseen, unrecognizable, insidious horror in our garages and in our streets, polluted with exhaust gases containing lead.

The public expect that an alert and intelligent Government will protect them against this, until investigators can assure them positively that there is no risk to public health. It can be said in advance that no men of wisdom who have experienced even the old form of lead poisoning can make such an unscientific statement. The least that they could say is that, while finding no positive evidence of danger, there may be protracted summative ill effects on health which baffle experimental investigation. The soothing parliamentary reply "no evidence of danger" is not enough, and yet positive elimination of all possible perils by experimental investigation is unattainable. I have read all the Blue Books on lead poisoning and know the difficulty of getting evidence.

Switzerland—an intelligent, well-educated country—has made lead-petrol illegal, and we should do the same provisionally. Another point is that the stuff should be called—compulsorily—by the warning name "lead-petrol" and not by the pretty euphemism of ethyl-petrol.

*Point (3).*—Turning now to the countervailing advantages for the motorist, I have inquired of experts, and find that the chief claim is elimination of "pinking" in high compression engines. But "pinking" may also be eliminated (in some cases better) by using a benzol mixture or by cleaning out carbon or tuning the ignition or carburettor. The use of this fuel in aeroplanes may be in a different category, and the public would not mind if it were allowed under supervision. But, so far as I can gather, the motoring advantages are not indispensable, and are small compared with the risks to health. Certainly I would not use it.

The problem is a confusing one to get into proper perspective. Neither the politician, nor chemist, nor motorist, nor the public is likely to see all round it. The medical profession alone can envisage its insidious dangers. They alone are aware of their powerlessness to answer a patient who asks "Am I suffering from mild poisoning from lead-petrol?" or "Will my health suffer if I work for months or years in a garage using lead-petrol?" Until, at any rate, they can answer these questions, doctors must

condemn the domestication of a deadly, insidious, and cumulative poison, even though it is highly diluted.

We should not pandor to the erudo mechanism of the motor at the risk of damaging the exquisite bodily machinery of our citizens and workmen.—I am, etc.,

Hull, March 1st.

FRANK C. EVE, M.D., F.R.C.P.

P.S.—The Ministerial reply (March 1st) that lead-petrol is to be allowed because latterly "no cases of poisoning" have occurred may be true and yet quite misleading. Translated medically, it may mean that in tetra-ethyl lead factories any man with suspicious symptoms is promptly changed to other work, while, outside factories, severe poisoning is unlikely to occur, and mild poisoning will not be recognizable. Hence "no cases of poisoning" are reported, though lots of minor poisoning may occur. The only safe course is to banish a poison until at least doctors can recognize its minor toxic effects, as they could with the old forms of lead poisoning.

\*\* There is no doubt that pure tetra-ethyl lead very readily produces poisoning. The whole difficulty of the matter lies in the fact that at present there is not sufficient evidence that the use of lead-petrol leads to toxic effects. The forthcoming appointment by the Government (announced in our last issue at page 381) of an Interdepartmental Committee to investigate the subject is a step which will be generally welcomed.—En., B.M.J.

#### DEFECTIVE STRUCTURE OF TEETH.

SIR,—With regard to the questions asked in your annotation on defective structure of teeth in the BRITISH MEDICAL JOURNAL of February 11th (p. 229) may I first say how much I appreciate the frank and friendly criticism of points which are, as stated in the article, only side issues? In reference to these points I should like to make the following observations.

1. As to the possibility of error in my definition of hypoplasia. I think that the evidence I have adduced suggests very definitely that the normal dentine of both the dog and man does not contain "interglobular spaces." The late J. Howard Mummery, in his *Anatomy of the Teeth*, states that interglobular spaces are usually associated with very conspicuous defects in the enamel, and are probably occupied by the uncalcified ground substance of the dentine. The small spaces of the granular layer of Tomes are usually confined to the dentine beneath the cement, but may occasionally, though very rarely in man, be found under the enamel. In comparing interglobular spaces with the granular layer of Tomes, Mummery says:

"The fact that the tubes of the dentine communicate with the spaces of the granular layer, while in the larger spaces they form no such communication, would apparently point to the explanation that the spaces of the granular layer represent a normal and functional structure, while the larger spaces are due to a defect in calcification."

The spaces to which I referred resemble interglobular spaces, and not those of the granular layer of Tomes.

You cite cetacea as creatures whose teeth show large numbers of interglobular spaces. As far as my knowledge goes, these animals are degenerate land animals whose teeth, when present, are often greatly modified. Cetacea occupy such an exceptional position in nature that arguments based on the structure of their teeth can be of little significance; moreover, the "spaces" in their dentine resemble those of the granular layer of Tomes rather than interglobular spaces. In some other animals interglobular spaces are seen occasionally—for instance, in horses, rabbits, and monkeys. Certainly in rabbits and rats they are easily produced by diets similar to those used in the puppy experiments, and they are equally easily prevented by adequate diets. Interglobular spaces are, however, rare in animals living under their natural conditions; but the teeth of civilized man, who lives under artificial conditions, usually, in my experience, display such spaces.

2. You suggest that Fig. 14 indicates that environment is more important than structure in producing caries. This is not, I think, a correct interpretation of the illustration. As is usual in the teeth I have examined there

is some normal dentine near the amelo-dentinal junction; this is well shown in Fig. 14. When the dentine is decalcified by acids the "spaces" often appear to be obliterated, as might be expected. This tendency is indicated in Fig. 14. In this figure the part of the tooth chosen for photographing was that in which caries was least extensive, as the object of the section was to show the structure of the dentine, and not to indicate the presence of caries. The greater part of the tooth was, in fact, carious.

3. From the evidence I have of calcification in puppies' teeth it seems clear to me that in those regions where calcification usually takes place most quickly the dentine tends to be worst calcified.

4. Fat-soluble vitamins have been shown to play a part in the resistance of teeth to caries.<sup>1</sup> The fact that the mother sacrifices her tissues to a certain extent for the sake of the developing offspring needs no comment. Experiments mentioned in the paper show that when a bitch is fed during pregnancy and lactation on a diet deficient in fat-soluble vitamins the deciduous teeth of the offspring are not as badly calcified as the permanent teeth would be if the same diet were given to the puppies after weaning. (Puppies' deciduous teeth are all erupted before weaning.) From this it seems probable that the mother has sacrificed some at least of her store of calcifying vitamin. If, as I have indicated, fat-soluble vitamins are of importance in resistance to caries, then the teeth of the pregnant woman might be expected to be more liable to caries than those of the non-pregnant, other things being equal.—I am, etc.,

MAY MELLANDY,

Pharmacology Department, Sheffield University,  
March 3rd.

#### CHEMISTRY AND PHARMACOLOGY OF ERGOT.

SIR,—In the article on ergot poisoning among rye bread consumers (February 25th, p. 302) we noted with surprise that the authors claim that "extracts from the rye were also tested physiologically for ergot, and the results were positive."

One of us (J. G.) prepared an extract from 600 grams (roughly 20 oz.) of the suspect flour, using the approved method of the U.S.P. X for "Fluidextractum ergotae." The neutralized extract was tested by the other (A. D. M.) on the isolated virgin guinea-pig and rat uteri, the blood pressure of the spinal cat, and also by the more specific test of intramuscular injection in the white Leghorn cock. The extract contained a histamine-like substance, but there was no evidence of ergotamine. Another extract, supplied by the city analyst, was even less active, so that our observations were diametrically opposed to your authors' conclusions, quoted above.

Microscopic examination, while revealing moulds, was similarly negative as regards ergot.—We are, etc.,

A. D. MACDONALD.

JAMES GRIER.

The Victoria University of Manchester,  
March 6th.

SIR,—In the interesting article on ergot poisoning among rye bread consumers by Drs. Robertson and Ashby, published in your issue of February 25th (p. 302), the following statement occurs:

"The three chief constituents of ergot are sphacelinic acid, cornutine, and ergotine. However, ergot is not as yet definitely split up into its component parts or active constituents, and little is at present known of them specifically."

This statement does not quite accurately represent the present position of the chemistry and pharmacology of ergot. From 1906 onwards chemical and pharmacological investigations conducted in our experimental department at Dartford and at the Wellcome Physiological Research Laboratories have shown that ergot contains the active alkaloid ergotoxine and the closely related inactive alkaloid ergotinine. Associated with these are a number of "putrefactive bases" produced by the action of the fungus on the proteins of rye grain, the most important of these being histamine ("ergamine") and "tyramine." In 1922 Spiro and Stoll isolated from ergot a new alkaloid

<sup>1</sup> British Dental Journal, October 1st, 1926, and December 15th, 1927.

ergotamine, which has qualitatively and quantitatively the same pharmacological action as ergotoxine. The questions that remain to be answered are: Is ergotamine identical with ergotoxine, and, if it is not, does it partially or wholly replace the latter alkaloid in certain varieties of ergot? From a medical point of view these questions are of academic importance only.

The facts given above are generally accepted; they are quoted, for example, in English, German, and Swiss textbooks on alkaloids, and are duly recorded in modern textbooks on pharmacology. It would in fact appear that probably no other natural drug has been so thoroughly investigated, both chemically and pharmacologically, as ergot, and in no other case can the activity of the crude drug and its extracts be so exactly associated with its known active components.—We are, etc.,

BURROUGHS WELLCOME AND CO.

London, E.C.1, Feb. 29th.

#### GASTRIC SECRETION OF NEUTRAL CHLORIDE.

SIR,—It is apparent that Professor MacLean thinks that I was guilty of some discourtesy in my previous letter, and if I really gave him cause I am extremely sorry, for it was far from my intention. Here, with the good news that his work is shortly to be published, I would gladly leave the matter; but his final paragraph shows such misunderstanding of my attitude that I must add something more. I think the truth is that Professor MacLean modestly underestimates the importance of his conclusions. To prove that normal gastric juice ever contains chlorine in any form other than that of hydrochloric acid is to disprove the united testimony of all the brilliant array of physiologists who have worked in this domain in modern times. This is no mean achievement, and it is surely not one that can suitably be dealt with by private correspondence. By the courtesy of the Biochemical Society it was my privilege to be present at their meeting to which Professor MacLean referred, and I made some observations in the discussion which followed his paper. The chairman, in his introductory remarks on that occasion, reminded us that the proceedings were private, so that Professor MacLean's communication was not even technically a publication, and all of us who heard it have had our lips sealed on the matter from that day to this. Perhaps at this date I may suggest, without any breach of confidence, that Professor MacLean's memory is playing him false when he says that the evidence I ask for was "fully communicated" at that meeting; he cannot be basing a statement of conclusive proof merely on the observations then made. This was in November, 1926. In the meantime the news of his conclusions has leaked out pretty widely, and I have been asked by members of my class how my views are tenable in view of Professor MacLean's recent work. It was February, 1928, when I wrote my letter, so that I have waited fifteen months before asking for the evidence; if this is fairly described as "rushing into print," I think I may claim pre-eminence in epistolary slow motion.—I am, etc.,

London, W.14, March 3rd.

GORDON W. GOODHART.

#### THE ACUTE ABDOMEN.

SIR,—It is quite clear that the somewhat earnest discussion which has been appearing in your columns arises from honest misunderstanding. The result, however, has been good, because once again the very difficult problem of diagnosis in acute abdominal disease has been forced to the front.

The surgeon who invariably operates early, and on slight signs, will miss nothing, but he will be faced every now and again by negative findings. He may, in most instances, succeed in thrusting these latter aside by the claim that no harm has been done, but, unfortunately, the parties interested do not always approve.

Much has yet to be done in the way of reaching agreement upon the earliest signs of surgical abdominal disease, but things are progressing rapidly. I think that too much is being said about those who wait for late symptoms. There are very few sinners in that respect now in practice.

One of the most impressive improvements in recent years is the anxiety of practitioners to refer their patients to the surgeon in the earliest hours of disease. The statistics of every hospital prove that. Neither general practitioners nor surgeons can be held responsible for delays brought about by patients or their relatives.—I am, etc.,

Glasgow, March 3rd.

CHARLES BENNETT.

#### PEPTONE TREATMENT OF ASTHMA.

SIR,—Perhaps I may be allowed to refer to a statement in the letter of Dr. James Adam in your issue of February 25th (p. 328). Referring to peptone, he says, "It may be dangerous, and many deaths have been recorded in America after its use." I have often pointed out that certain peptones are dangerous to give internally, but that I have never found the slightest danger with Armour's No. 2, after using it for many years. I have not, however, heard of deaths in America produced by any peptone. Perhaps Dr. Adam would kindly give us the references to these "many deaths."—I am, etc.,

London, W.1, Feb. 25th.

A. GUNN AULD.

#### MEDICAL EXAMINATIONS FOR LIFE ASSURANCE.

SIR,—While ready to agree with Dr. W. M. Robson that time is wasted by applicants being unprepared to micturate, I cannot by any means endorse the whole of his letter of February 20th which appears in your issue of March 3rd (p. 376).

No insurance company cares a straw for the exact ages of brothers and sisters. What is wanted is their relation to the age of the applicant; indeed, even the ages of parents are only important for the same reason. The word "about" may be appended to the figures given, and will salve the conscience of the ultra-scrupulous applicant—and there are such! But my experience is that to ask these details gives the examiner a valuable opportunity of gauging the truthfulness, or otherwise, of the applicant, and is a useful guide in assessing the value of his replies to more personal queries.

As to permitting women to bring urine in a bottle, let me recount one experience. I was once instructed to visit a lady of very exalted title at an hotel. I made the usual request for a specimen, and the lady retired to the adjoining bedroom in her suite. But I had taken the precaution of hiding a chamber vessel which I had found containing urine, and which I had reason to suspect had been passed by her ladyship's maid. As a result the urine passed at my request was found to contain sugar. I never allow urine to be brought in a bottle, and if the applicant has to be left to himself or herself I always satisfy myself that the urine is warm.

One further detail: I have in reserve a urinometer which can give the specific gravity in less than one ounce of fluid.—I am, etc.,

London, E.C.2, March 3rd.

A. OGIER WARD.

#### ULTRA-VIOLET LIGHT TREATMENT OF LUPUS ERYTHEMATOSUS.

SIR,—The remark of a speaker at the meeting of the Medical Society of London, recorded on February 18th (p. 259), to the effect that treatment of lupus erythematosus by ultra-violet light is "waste of time and effort," prompts me to record a recent experience of mine exactly to the contrary. I extract the following notes from my case-book.

March 9th, 1927.—Mrs. —, aged 47, family history unimportant, complains of an eruption on the right side of the face of twenty-six years' duration. There is typical lupus erythematosus extending over an area roughly semicircular in shape, and two inches in diameter, in front of the right ear. There is a very small thin scar in the centre of this area. The lobe of the ear, anteriorly and posteriorly, and the pinna, anteriorly to a slight extent, are involved.

A mask was made for the face to protect the unaffected area, and treatment was begun on March 6th. The patient received two local radiations per week from a mercury vapour lamp, the time of each exposure gradually

increasing from two and a half to ten minutes, and the distance diminishing from thirty to six inches. The lesion slowly but steadily improved, and on December 9th treatment was discontinued.

January 17th, 1928.—The eruption has completely disappeared, and the scar is so fine that it is hardly perceptible. Closer inspection reveals a small scale on the edge of the pinna.

I should add that no lotions, ointments, or dressings were applied to the affected area, and that only two general radiations were administered, the patient having refused any more because of the subsequent irritation of the skin. Probably the entire absence of local applications of ointments or lotions made the light therapy more effective; at any rate, one must agree with Dr. Heald that "a curious difference in clinical results" calls for more investigation.—I am, etc.,

Sunderland, Feb. 21st.

NOEL F. ROWSTON.

### INJECTION TREATMENT OF VARICOSE VEINS.

SIR,—In South Africa, where, as a nation, we are particularly free from syphilis, we have a great opportunity to observe the condition of varicosity of veins as it arises in the European and native races; some of the latter are heavily and widely infected, whereas some are not infected at all. Among the non-infected no varicose veins are found, but among infected persons—especially in hereditary cases—instances of varicosity occur.

The standard treatment, either by operation or by producing thrombosis, must in itself appear a crude temporary measure unless it cures the cause of the complaint, which, from a pathological point, is the same as aneurysm—in fact, it is inferred from the textbook statements.

I came to use "606" in the treatment of the varicose condition because I had to treat a patient who thought he had syphilis in a mild form; the Wassermann reaction of his blood was slightly positive. Knowing that he had varicose veins in both legs I injected a vein; to my astonishment, a few days later I found that the varicose condition had entirely disappeared. Since then I have always treated all varicose conditions and especially the accompanying hard ulcers so common among the poor, by arsenical compound injections, with the happiest results, as the ulcers heal up in about a fortnight without any special treatment except the concomitant mercury pills (Hutchinson's formula).

No one now suggests that arsenical compound preparations form thromboses in the veins, since the same vein can be used for months for the injection, showing that it has not become occluded in the course of treatment. The great objection, in my opinion, to the use of other drugs which do not attack the cause of the disease, but produce thrombosis, is the risk of embolism. Moreover, the principle of thrombosis is wrong, inasmuch as it throws a greater burden on the yet uncured veins. I am confident that the use of the arsenical compounds will become standard in all varicose conditions; I can especially recommend it for that intractable condition of varicose ulcer. In the case of a sleepwalker, aged 24 years, I used the same treatment after finding from the family history that his mother and two elder brothers died before the age of 38 from apoplexy. The effect of the first injection was complete cessation of the sleepwalking. He had in all three injections; incidentally, his piles were cured as well as a Circe's girdle of veins due to obstruction of the veins of the liver. I saw him in 1916 when he was suffering from chronic syphilitic rheumatism.—I am, etc.,

Uppington, South Africa.

W. M. BORCHERS.

SIR,—It may not be out of place to give some reasons why thrombosis need not be considered as a possible factor against the use of injections for varicose veins.

If 20 per cent. strontium bromide is injected into a varicose vein and a metal disc is placed over the site of the needle mark an immediate radioscopia will show that not a particle of the opaque substance goes above the metal disc, but on the contrary falls distally from it—that is to say, against what would be the normal venous flow in a healthy vein. By this same method the theory

of Trendelenburg, or the reversal of the blood stream in varicose veins, is proved to be correct. This, therefore, is one reason why a blood clot has no tendency to get into the general circulation (Yentzer). The first effect on the veins of an injection of certain substances is a chemical inflammation and destruction of the endothelial cells, with subsequent sclerosis of the vessel walls. The clot which forms after the endothelium has been destroyed is firmly adherent to the vessel wall.

The risks attending thrombosis and emboli are practically nil. There is far more danger from errors in technique. It must be borne in mind that great care and attention to asepsis are necessary when injecting the fluid into the vein. Not a drop must be allowed to get into the surrounding tissues, since great pain, and even a slough, may be caused, just as with injections of arsenic or mercury. The injections well done are painless, except for a cramp that spreads along the leg. It lasts only for a short time, and is of good omen with regard to the ultimate success of the treatment. It is only right to emphasize the fact that unless great care is taken in giving these injections complications may occur which would tend to discredit this form of treatment in the eyes of the practitioner and the public. When well done no form of treatment for this condition gives such rapid, lasting, and gratifying results. It is a boon to all classes, since they need not curtail their work nor their pleasure. The thrombus in ligatured vessels and in veins treated by injections does not become detached unless it is infected.—I am, etc.,

London, S.W.7.

T. HENRY TREVES BARBER, M.D., B.Sc.

### THE FUTURE OF OBSTETRICS.

SIR,—I was delighted to read the comments of Dr. G. W. Theobald of Bangkok (February 18th, p. 284) on my letter published in your issue of December 10th, 1927 (p. 1117), and I agree with much he has said.

The medical practitioner of to-day is far too often passed into the world of medicine with a scanty knowledge of obstetrics, and it is for the centres of teaching to supply that deficiency. I quite agree that so long as a midwifery case is progressing it should be left to Nature. I consider an enema a matter of course, but a catheter as a routine practice is an abomination; morphine, scopolamine, and tincture of opium are dangerous expedients that too often mask symptoms which are leading up to difficulties. These difficulties have to be dealt with after much unnecessary delay, indicating a want of perception of the causes of that delay.

Dr. Theobald suggests that strict asepsis is unattainable. I argue that asepsis is the chief and only point to be arrived at, and should be applied in midwifery in exactly the same way as it is in surgery. Where should we be but for the advance in this respect in surgery, and why should we fail in the attempt to bring midwifery up to the same standard? After forty years' practice, and having attended over 4,000 confinements, I claim that forceps, dilators, and turning can be aseptically applied in midwifery under reasonable conditions, and I have no regrets on the subject.

Midwifery in private practice is not the same as institutional treatment, and I consider that cases in institutions are often left far too long for the good of the patient; this would not be tolerated in private practice. It is often asserted that private practitioners have no time or patience to give a case decent opportunity to progress slowly, but it is not the truth; a general practitioner is as conscientious as anybody else, and it is high time that these offensive assertions were dropped and that fair play was allowed him. Axis-traction forceps, being scientific instruments, are invaluable in whatever position the head may be; ordinary forceps are out of date. I contend that when the head has come to the outlet of the pelvis—otherwise on the perineum—the time has come rather to take the forceps off than to put them on.

I have read and digested most of the papers Dr. Theobald mentions, and expressed my views in the *BRITISH MEDICAL JOURNAL* of January 22nd, 1927 (p. 164).—I am, etc.,

Wallington, Surrey, Feb. 21st.

A. Z. C. CRESSY.

## A SOCIOLOGICAL FORMULA.

SIR,—In view of your welcome report of Mr. C. J. Bond's Galton Lecture on eugenics (February 25th, p. 315) I beg to submit a sociological formula which would serve for all countries and for all time. The fundamental consideration in sociology is the very strong tendency of population to press upon the means of subsistence. This tendency must be completely counteracted if a satisfactory standard of living is to be maintained, and three factors are necessary to counteract it completely—namely, high production, a low birth rate, and eugenic selection. Thus I arrive at my formula: People must work their best, and also must not have more than two children unless they are above the national average in the advantages for parenthood. I assume that if the less eugenic couples do not have more than two children the others will be proud to have larger families.—I am, etc.,

London, S.W.7, Feb. 25th.

BINNIE DUNLOP, M.B., Ch.B.

## POLYDACTYLISM AND REVERSION.

SIR,—The case of supernumerary thumbs reported by Dr. R. H. Mitchell (February 25th, p. 308) raises interesting points. Darwin in his work *The Descent of Man*, chapter ii, page 55, says:

"I attributed, though with much hesitation, the frequent cases of polydactylism in men and various animals to reversion. . . . I was chiefly led to the conclusion that the presence of supernumerary digits might be due to reversion from the fact that such digits not only are strongly inherited, but, as I then believed, had the power of regrowth after amputation, like the normal digits of the lower vertebrata. . . . But at present it is the safest course to give up altogether the idea that there is any relation between the development of supernumerary digits and reversion to some lowly organized progenitor of man."

As Dr. Mitchell remarks, the lack of hereditary influence in his case makes the occurrence somewhat remarkable. Since the patient underwent an operation it would be interesting to be informed later whether there was evidence of any power of regrowth.

Haeckel asserted that the five-toed amphibian foot was formed from the many-toed fish fin (*Evolution of Man*, p. 306). It is a long way back in the animal scale for such a reversion to recur in man; even the interval between one of the apes and a fish is immense. Personally I do not think that Darwin realized the fact that polydactylism is more common than the occurrence of a tail, since otherwise he would not have made this statement about reversion. The question naturally arises, Can a human tail be looked upon as a reversion?—I am, etc.,

REGINALD COCK, M.R.C.S.Eng., L.R.C.P.

London, E., Feb. 26th.

## The Services.

## DEATHS IN THE SERVICES.

SIR ROBERT PORTER.

Major-General Sir Robert Porter, K.C.B., Army Medical Service (retired), was taken ill during the memorial service to Lord Haig in Westminster Abbey, and died of pneumonia and pleurisy a week later at his residence at Beckenham, Kent, on February 27th, aged 70. He was born in County Donegal on January 31st, 1858, the son of the late Andrew Porter, and educated at Foyle College, Londonderry, at Glasgow University, where he graduated M.B. and Ch.M. in 1879, and in Paris. He entered the R.A.M.C. as surgeon on February 5th, 1881, attained the rank of colonel on January 14th, 1910, and, after a four years' tour of office, was placed on half-pay on January 14th, 1914. Recalled to duty at the beginning of the great war on August 5th, 1914, he was appointed temporary surgeon-general on November 2nd, 1914, and confirmed in that rank—the title of which was subsequently changed to major-general—on February 18th, 1915. He retired after the war on March 3rd, 1920. He had a very fine record of war service, before as well as during the great war. His first active service was in the Ashanti campaign of 1895-96, when he was mentioned in dispatches and received the star given for that campaign.

He served throughout the whole South African war of 1899-1902, when he took part in operations in Natal, the Transvaal, the Orange River Colony, and Cape Colony, including the actions at Elandslaagte and Lombard's Nek, and the defence of Ladysmith, and received the Queen's medal with five clasps and the King's medal with two clasps. During the war of 1914-18 he was D.M.S., from 1914 to 1917, of the Second Army, the army which held Ypres throughout, and which maintained the long and bloody struggle of Passchendaele. Towards the end of this time this army had grown in strength to 800,000 men, and he had under his administration some twelve hundred medical officers, employed in twenty-eight Divisions, as well as in some thirteen casualty clearing stations, fourteen sanitary sections, three mobile laboratories, and five army schools of sanitation—a vast organization which he had himself built up. He was six times mentioned in dispatches—in the *London Gazette* of October 19th, 1914, February 17th, 1915, June 22nd, 1915, January 1st, 1916, May 29th, 1917, and December 24th, 1917. He was awarded the C.B. in 1916, and the Crown of Belgium, as commander, in the same year, the C.M.G. on June 3rd, 1919, and the K.C.B. on January 1st, 1921. He also had the Belgian Croix de Guerre. In 1903 he married Mary, daughter of the late John Johnstone of Barnard Castle, and leaves a widow and three sons.

Lieut.-Colonel Charles George Webster, Madras Medical Service (retired), died at Ryde, Isle of Wight, on January 26th, aged 56. He was born on July 5th, 1871, the son of the late John Henrie Webster, Government Telegraph Department, Chaudanagore, Bengal, and took the Scottish triple qualification in 1892, and subsequently the F.R.C.S. Ed. in 1905. Entering the I.M.S. as surgeon lieutenant on July 29th, 1895, he became lieutenant-colonel on January 29th, 1915, and retired a year later on January 29th, 1916. He served in the China war of 1900, receiving the medal. He entered civil employment in the Madras Presidency in January, 1902; in 1909-10 he held the professorship of medical jurisprudence in Madras Medical College, and in June, 1914, was appointed surgeon of the 1st District of Madras City.

## Universities and Colleges.

## UNIVERSITY OF CAMBRIDGE.

At a congregation held on March 3rd the following medical degrees were conferred:

M.B., B.Chir.—S. J. P. Gray, M. J. Harker, R. M. B. MacKenna, K. H. Uttley.  
M.B.—J. Dockray, H. K. Goadby, H. B. Stallard.  
B.Chir.—W. J. H. M. Beattie, D. R. Tweedie.

## UNIVERSITY OF LONDON.

At . . . . . examination held in January there were  
197 . . . . . in the first division and 880 in the second  
div' . . . . . took the supplementary certificate for  
Latin.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

## COUNCIL ELECTION.

THE Secretary of the Royal College of Surgeons has sent out the usual election notice, which on this occasion informs the Fellows of the College that on Thursday, July 5th, there will take place an election of four Fellows into the Council in the vacancies occasioned by the retirement in rotation of Sir Anthony Bowlby, Bt., Sir D'Arcy Power, and Mr. F. J. Steward, and by the death of Mr. W. Thelwall Thomas.

Blank forms of nomination and of the requisite notice from a candidate may be obtained on application to the Secretary, and the same must be received by him, duly filled up, not later than on Monday, March 19th. A voting paper will be sent by post on April 3rd to each Fellow whose address is . . . . .

The candidate elected by the smallest become substitute Member of Council for Thomas until 1935.

## Museum Demonstrations.

The following demonstrations of specimens in the museum will be given in the theatre of the Royal College of Surgeons of England by Professor Sir Arthur Keith.  
advanced students and medical  
the dates indicated at 5 p.m.: Ma  
of the sacro-lumbar region of the spine and their bearing on  
surgical practice; March 16th—Variations and anomalies of the  
cervical and costal series of the vertebral column and their applica-  
tion in diagnosis and treatment; March 23rd—A review of the  
present state of knowledge regarding the innervation and move-  
ments of the intestine.

MARCH 10, 1923]

[ THE BRITISH  
MEDICAL JOURNAL

*Deborah Williams*

of the standard of accuracy maintained by the *Journal* and of what is called its "news value" may be inferred from the attention they paid to our columns. Lord Northcliffe, who had a sure instinct for such things, is reported to have said that "the Editor of the *B.M.J.* must be a man who knows news when he sees it." Dawson Williams, when he heard this, remarked with a quiet chuckle that it was rather fun to note how often a good hare started in the *British Medical Journal* was hunted, first in the *Times*, and then up and down the press of the country.

In the scope of this notice it is not possible to deal with all the activities of thirty fateful years, but we cannot omit mention of Dawson Williams's action in bringing about the highly successful scientific and clinical meeting held in London by the Association soon after the war, or the work he did with the help of Dr. Johnson Horne, many years earlier—in 1904—in arranging for the reception and entertainment of 150 leading French physicians and surgeons who then paid a formal visit to London. Yet his habitual modesty was such that in the full reports of those proceedings in the *Journal* no mention of his name is to be found. During the war, when he worked for many months almost single-handed, he gave unflinching and effective support to the Naval, Army, and Indian Medical Services, and forwarded with all means at his command their best interests in war, as he had done in peace, believing that those interests were inseparable from those of the rank and file of the fighting forces. Although he had had no personal experience of general practice he had a deep understanding of the difficulties and needs of general practitioners, and championed their interests at least as much as those of any other branch of our profession.

His literary gifts may almost be left to speak for themselves in the pages of this *Journal* during the past forty years. Under his direction it was not merely a record of progress in medical science and an organ of professional opinion; it had a quality that stamped it, for those who cared for such things, as the production of a literary artist with a fine sense of values. He thought of the several parts of each issue as making up a whole, and spent infinite pains over correcting slovenly workmanship, even in the smallest paragraph. Like every true editor he took more pride in the good work of a chosen contributor than in anything from his own pen. What he himself wrote was always sound English—direct, vigorous, never commonplace; free from affectation or mannerism; a style that fitted itself naturally to the matter in hand, without waste of words. The last sentence he wrote for publication was at the end of an article on the *Oxford English Dictionary*, in the issue which appeared two days before his death: "Its motto might be 'Thorough.'" It was certainly his own motto.

In recognition of his services to the R.A.M.C. during the war he was made C.B.E. in 1919, and he received the honour of Knighthood on January 1st, 1921. Other distinctions, well deserved, fell thick upon him. In 1921 he received the Gold Medal of Merit of the British Medical Association—the highest honour which the Association has to bestow. From Durham University he received the honorary degree of D. Litt., from Glasgow the LL.D., and from Sheffield its D.Sc.

Despite the remonstrances of some of his medical friends, he would not consent to take life more easily and relax the close personal supervision which he had always given to the contents of each issue of the *Journal*. As long as he held the post of Editor he insisted on doing his share—and indeed more than his full share—of the hard routine work, except during the spells of illness when his absence was enforced. At last, in December, 1927, he handed in his resignation, which was accepted by the Council with heartfelt regret that so long and close an association should perforce have to end. He had talked of this step for some six months, but not unnaturally wished to complete his long term of thirty years of service as Editor, which he reached in January last. As recorded in our issue of January 21st, his last attendance at the editorial office was on January 19th, and on the evening of that day he was presented with his portrait by his immediate colleagues at an informal dinner party.

On the news of his retirement becoming known it was

felt very generally that, as stated in a circular signed by a group of representative members of the profession, "this occasion should not pass without some recognition from the profession as a whole of his great services to medical journalism and so to the science and practice of medicine." Steps were accordingly taken to raise a testimonial fund, and a public announcement was made on February 25th. Unfortunately for his friends and admirers, Dawson Williams is beyond the reach of such witness to the affection and esteem in which he was held, but he lived long enough to be aware of what was afoot, and to let it be known that he for his part would wish that any testimonial should take the form of an endowment for the furtherance of research by way of scholarship or prize. It will be for the Committee of the Fund, of which Sir StClair Thomson is Treasurer, to decide, in consultation with the subscribers, on the precise object to which the money that may be collected had best be devoted in association with his name. The project has by no means ended with the death of our chief, and we hope that in the form of a Dawson Williams Memorial Fund it will go forward to fruition as a worthy monument to one who did incomparable work for British medicine.

Some eighteen years ago Dawson Williams was injured in a motor car accident and severely shaken, as well as incurring a bad strain of the wrist, and during the last decade he suffered more and more often and more severely from bronchitis, attended by a disquieting inadequacy of the heart's action. After one of these attacks in 1924 he wrote: "I wish I wasn't so old; the world is very interesting." Despite increased weakness of body, his interest in all that went on did not diminish, and just after his retirement was decided upon he wrote to a friend: "How I shall like to have no definite occupation I do not know, but possibly better than I fear." And in another letter to the same correspondent he said that, as he had always had "one foot in the country," he did not dread giving up his quarters in London, seeing that he would still be within easy reach of Town. Fortunately for him his newly acquired leisure had not had time to pall; he had just finished ordering his private affairs when he was struck down while on the way to take train to visit a friend in London.

In person Dawson Williams was an impressive figure. Well above six feet in height, he was of commanding presence, until of late years sickness and over-anxiety wasted his body and he stooped somewhat. But up to the last no one could fail to notice him even in a crowd. Strongly marked eyebrows and an aquiline nose gave severity to his expression when he was displeased, or disgusted with any display of meanness or bad faith; but the frown swiftly melted into a peculiarly sweet smile when his wrath was appeased, and this characteristic smile lit up his face at the sight of an old friend. He was by nature an aristocrat, and the almost autocratic position he held suited his disposition. Democracy did not attract him, for he believed, and could bring forward instances in support of his belief, that (in his own words) the best results were achieved by the people acting under the direction and control of their natural leaders.

It is not necessary for us to dwell further on the many-sided character of our late Editor, because this is revealed in the large number of appreciations, printed below, which have been sent to us by leading members of the profession. They depict the man and his work from widely different aspects, individual or official, and their effect taken as a whole is that of a composite portrait. To attempt to fit them into a formal pattern would, we believe, be a mistake, even if exigencies of time and space had not made it impracticable to do so. These tributes, therefore, follow one another very much in the order in which they seemed to group themselves after most of them had come to hand. The same note of admiration and warm personal feeling runs through them all, and together they seem to us to bring before our readers' eyes the man as he was—a great and good man wise and far-seeing and true-hearted. Dawson Williams was loyal through and through—to his paper, to the Association and the profession, and to everyone with whom he worked or who worked under him. The *British Medical Journal*, and all that it stood for, was his life.

## PERSONAL APPRECIATIONS.

Sir ROBERT PHILIP, M.D., LL.D., President of the British Medical Association and Honorary Physician to the King in Scotland, writes:

The message that Dawson Williams had suddenly gone from us brought me a keen sense of loss and loneliness. He had remained the one close link with the moving spirits of the Association as they were when I was admitted a member more than forty years ago. It was at the Annual Meeting in Dublin in 1887 that I met him for the first time. His handsome figure, open countenance, good-humoured smile, and friendly bearing quickly won my affectionate regard. This has steadily grown as the years have passed.

In 1898, when Dawson Williams hitched on to his broad shoulders the mantle which had dropped from the slender but forceful frame of Ernest Hart, I saw a good deal of him. For it was the year of the Meeting of the Association at Edinburgh, when I happened to hold the office of Local Secretary. Previous to the meeting, and throughout the meeting, his thoughtful kindness was that of an elder brother. Along with Francis Powke, the General Secretary, he placed his experience and resources lavishly at our service with old-world delicacy. After the meeting he came for a short while to our little country house. Only the other day he recalled to me, with pictorial freshness which astonished me, incidents of that visit which had almost faded from the memory of his host and hostess: how, for example, having unwittingly hoarded an express which did not stop at the little country station, he watched his opportunity, and when the train was held up midway on the line by signal, "disboarded" it unconventionally and tramped, bag in hand, over dykes and through meadows until he struck a likely road which landed him in time for dinner; and, again, how he set himself successfully to solve the enigma of why our fruit progressively disappeared from the garden in the early hours of the morning. Throughout the intervening years since the 1898 Meeting, the early impression of his quality has increased in clearness and depth. Williams's personality was a fine blend derived from breeding and training. He was vertebrate throughout. The handsome framework, built on generous lines, enclosed a like mentality. Chief qualities in the blend were integrity and sagacity. Just and wise himself, he expected from others a high standard of conduct, and he preferred the wise man to the fool. In all his transactions he "sought to see the whole." Consideration of the interests of others made him look well round a question before speaking or doing. He was content to be slow rather than to be unfair.

He had a high conception of the doctor's calling. Physician by predilection and training, he watched the developments of medicine and surgery with discriminating eye. Ever ready, on the one hand, to appreciate sound advance, and, on the other, to be critical of that which savoured of quackery or humbug, he maintained a singularly detached attitude towards the changing movements of medical thought and practice. Those qualities found ample scope during his occupancy of the Editor's chair. His horizon was wide, and he scanned its varying aspect from week to week with clear eye, unbiased mind, kindly thought for others, and a nice sense of humour. In report he was accurate and succinct; in judgement he was considerate and just; in argument he was gallant and courageous. He would suppress no fact; he would blur no issue.

I remember, a good many years ago, sitting in the office, when an urgent letter was handed to him—as it turned out—from an influential member of the Association, highly critical of some line adopted by the *Journal*, and not without menace. Looking up from the letter he told me of the contents and the author. In reply to my "What will you do?" he remarked, with humorous glance and quaint movement of the shaggy eyebrows, that the bomb had exploded and he remained where he was.

To the end his foot trod the path where duty lay. Whenever he returns to us in memory, the portrait will be that of a cultured, considerate, courteous gentleman.

Sir DONALD MACALISTER, Bt., K.C.B., President of the General Medical Council and Principal of the University of Glasgow, writes:

My first acquaintance with Dr. Dawson Williams was made when I was appointed a member of an Editorial Committee to co-operate with Mr. Ernest Hart in the supervision of the contents of the *British Medical Journal*. The position was a delicate one, for Mr. Hart was a masterful man, and held strong views as to what the *Journal* should include. Occasionally the committee, in the presumed interests of the Association, had to question or veto some of his proposals. Dawson Williams, as Assistant Editor, attended our weekly meetings and took part in its proceedings tactfully, but always with effect. When our decisions involved disturbance of the proposed "make-up" of the *Journal*, and the Editor urged this disturbance as an argument against the committee, it was the Assistant Editor who turned the force of the objection by showing, with quiet skill, how the change could be carried out. I learned then, what I learned more fully in subsequent years, how sure and wise was the Assistant Editor's handling of men and affairs. When he became Editor of the *Journal*, his long apprenticeship to the craft fitted him uniquely for the responsibilities of office, and the Editorial Committee became a superfluity.

A good many years have elapsed since I perforce ceased to be connected with the Association or the *Journal*, but in these years I have had abundant opportunities of watching the Editor's steady advance, not only to mastery in the conduct of his paper, but to the command of sure confidence in his fairness and sagacity on the part of the profession at large. When in 1922 I was privileged, as Vice-Chancellor of the University of Glasgow, to confer on him the honorary doctorate, I shared with my academic colleagues the assurance that Sir Dawson Williams had most worthily won his spurs and earned his laurel.

Sir JONX ROSE BRADFORD, K.C.M.G., F.R.S., President of the Royal College of Physicians of London, writes:

In order to fill adequately the post of Editor it is necessary that a man should possess many qualifications; some of these may be acquired by diligent study, others are more fundamental in origin and depend really on character. Dawson Williams was thoroughly equipped in both directions, and well deserved the rather unique position that he attained. Those who, like the writer, had known him for a very long time—between forty-five and fifty years—were familiar with the wide range of his activities. As a young man, in the early eighties, whilst maintaining a very active interest in the practice of clinical medicine, more especially with reference to the diseases of children, he was one of a group of men, including Horsley, Sidney Martin, Halliburton, and others, who felt the desire to investigate some of the many problems that the awakening of physiological inquiry in this country brought to the front. It is an index of the breadth of his mind that, as long ago as 1883, he was engaged in investigations in the physiological laboratory of University College, London, allied to those of Sidney Martin, in what was then the very neglected field of so-called chemical physiology. I well remember him as a most patient, thorough, and diligent worker in the laboratory, but even in those early days he felt the call of writing, and throughout life his interest in books and of writing, old and new, was not only maintained, but was also fostered. As the years progressed this became the paramount interest, and the fields both of research and of practical clinical medicine were relinquished, and all his energies were concentrated on what was to be his main life's work. This, however, did not take place until he had achieved results of value in clinical research. He brought to the Editor's chair a first-hand knowledge, both of the scientific side of medicine and of practical clinical medicine, and this wide range of knowledge and of sympathy with the aims of both classes of workers was not only a very valuable asset in his editorial work, but formed also a rather unusual equipment in an editor. This was perhaps one of the reasons for the ready acceptance of his decisions by others. But the main reason for the respect and affection in which he was held was undoubtedly the

recognition by the profession of the sterling character of the man himself. Beneath a massive, rugged, and somewhat brusque exterior he concealed a kindly heart, and no one who had any sort of relations with him could fail to appreciate that his opinions, however bluntly given, were always determined by the sole consideration of what, in his judgement, was right, and to the honour and dignity of the profession of medicine.

The work of an editor must always be difficult, even when it is limited to the acceptance or rejection of scientific communications for publication, but when, in addition, it involves the consideration of matters that are termed "medical politics," the position is one calling for no common ability. The fact that Dawson Williams filled such a position for many years with credit to himself and with honour to our profession is perhaps the most fitting tribute to his memory.

Sir THOMAS BARLOW, Bt., K.C.V.O., F.R.S., consulting physician to University College Hospital and the Hospital for Sick Children, writes:

It is just forty-eight years since I first met Dawson Williams at University College Hospital. He was then house-physician, and I had been recently appointed junior assistant physician with regular charge of out-patients and occasional charge of in-patients. Williams was a square-set vigorous Yorkshireman, rather brusque in his manner, not aggressively argumentative; indeed a little reserved, but tenacious in his opinions, and able to give a good account of himself. He knew his medicine and was keen in every department. I remember that he took the gold medal in medicine at the London M.B. examination, and he was qualified for the gold medal at the M.D. He was an invigorating and stimulating resident. He and Horsley were close friends. I recall that at that time he showed an immensely practical outlook; he saw the wood as well as the trees. After he had completed his hospital resident posts he took some time to settle down to outside work. He did some pathological investigations for Dr. Wilson Fox, going through some of Dr. Fox's histological findings on the origin of tubercle and testing them by recent methods. For a time he was drawn towards medical hygiene; after a while he was appointed assistant physician at the East London Children's Hospital, Shadwell, and I recall a good clinical study by him on cases of glandular fever in children. In later years he wrote a small manual of children's diseases. Dawson Williams had a ready pen. He wrote good English and his views were stated in a fair and balanced way. When at length he joined the staff of the *British Medical Journal* it was soon obvious that he had found his true vocation, though I regretted that he had presently to relinquish his hospital work. He was always keenly interested in children's diseases, and he had true clinical enthusiasm. He maintained throughout his long career enthusiasm for the scientific advance of medicine, and was, to my personal knowledge, anxious to recognize, and emphasize original work and to give credit where credit was due. He was loyal to his editorial committee, but as years went on he strove to widen and deepen medical education and to maintain general medical policy on a lofty and honourable plane, in which partisanship and personal ambition had no place.

Sir HUMPHRY ROLLESTON, Bt., K.C.B., Regius Professor of Physic in the University of Cambridge, writes:

The passing of a great personality, even though his life's work has been done, cannot fail to be a sad break with old associations, and the sudden death of Dawson Williams recalls his activities thirty and more years ago as physician to the East London Hospital for Children, Shadwell, his book on *Medical Diseases of Infancy and Childhood* (1898), his early work on the "Glandular fever of childhood" (*Lancet*, 1897, i, 160), and articles on that disease, measles, and rubella in the first edition of Allbutt's *System of Medicine* (1897), before he abandoned active practice in a branch of medicine in which he ever remained keenly interested. A man of wide culture and many human interests—as shown, among other ways, by his clubs—he was exceptionally fitted by critical and other faculties

for editorial work; his success in a position rendered difficult by the changes in the constitution of the British Medical Association, and by many cross-currents of thought, is evidence, if it were needed, of the wisdom and extensive acquaintance with human nature, whereby he steadily maintained his ideals of medical journalism. Probably the influence he thus quietly exerted is most clearly shown by comparison of the *British Medical Journal* as it was when he assumed the full editorship in 1898 with its present character. The power he gradually acquired of forming and directing aright medical opinion was very real, and the affectionate regard inspired by his upright character enabled him to obtain leading articles and signed reviews from prominent and busy members of the profession. He was remarkable for absolute freedom from egotism and self-seeking, for his statesmanlike outlook, intense patriotism and devotion to British Medicine, generous help to young men trying to get their feet on the first rung of the professional ladder, and an open mind willing to give publicity to good work from unknown and unlikely quarters, even when departing from orthodox doctrines. The great position he established for medical journalism was slowly built up, and his well-deserved honours were chiefly of recent date. In one of the very few personal comments that I remember was the remark, in response to verbal congratulation on his knighthood in 1921, that it came too late to be of any use. He once admitted that he went into medicine from a desire to relieve the sufferings of others, and few men so sore let and hindered by family illness and personal disabilities have faced life more bravely and unselfishly. It is a satisfaction that before crossing the bar he must have realized the profession's appreciation, and that his labour had not been in vain.

Sir BERKELEY MOYNTHAN, Bt., K.C.M.G., President of the Royal College of Surgeons of England, writes:

The sudden death of Sir Dawson Williams will leave a gap in many lives, for few men had so great a gift of intellectual and emotional friendship for those privileged to know him well. My first contribution to the pages of the *British Medical Journal* was made at the time he became Editor. It was not long before he asked me to review works on surgery, and to write leading articles dealing with surgical problems. The help he gave me was incalculable; and I may truthfully claim that his formative influence upon my literary methods was greater than that of any other man. His comments might be ironical or provocative, but his shrewd insight made him see the full drift of an argument, and able to demonstrate how it might be carried further or presented more cogently or acceptably. A word of praise was never praise only: it was encouragement which gave a new direction to one's mind, and made one eager to do better. Discussions on phrases or on the logical and lucid presentation of a thesis soon led to references to literature in general. We quickly realized a similarity of taste. A devotion to the sonnets of Shakespeare, to Macaulay, and to Keats was acknowledged on our first encounter. It was always a joy to learn from him the books he had recently been reading, and to hear his fresh and illuminating comments or exposition. In literature, as in politics, he held tenaciously to opinions; his clarity of judgement, intellectual fairness, and wide experience made conversation with him a delight.

His help was given in far larger matters than these. When the National Health Insurance Bill was under discussion its chief protagonist was not always very friendly to the medical profession and its ideals and desires. The wounding accusation that doctors in pressing their claims were "bickering at the bedside" did not help to a better understanding or to easier discussions. It was at a time when tempers were roused and passions were ugly that I was asked to see the politician most concerned. Before luncheon with him I spent over an hour with Dawson Williams in sharp discussion on the many points then exciting controversy. The result of my very prolonged interview with the protagonist of the bill was expressed a day or two later in the *British Medical Journal* and other newspapers, which recognized in him "a changed attitude

to the medical profession"; and afterwards matters moved more smoothly. The credit for this was due entirely to the sagacity of Dawson Williams.

On other occasions, when as a member of deputations I had to see the Home Secretary, the Secretary of State for India, or other high Government officials, I never felt that I could be adequately prepared without a full discussion with Dawson Williams. I am convinced that the best friends of our profession are those members of it who hold high permanent position in Government offices; their opportunities for service to causes we uphold are innumerable and are fully enjoyed. Among others who can help, the editors of our medical journals have perhaps the greatest power. We hardly realize, I think, how fortunate we have been in recent years. The influence of Dawson Williams on that aspect of medicine which touches public questions was of the highest importance; it was exerted through many channels, on various occasions, and by diverse methods. He was a staunch, loyal, upright, and most powerful friend of medicine, with the insight and imaginative grasp of a statesman. It was his own reticence alone which prevented the world from learning this. The cause of medicine has lost in him one of the greatest advocates, and wisest and most powerful friends. To some he seemed austere and aloof; yet behind the obvious barriers there was a generous and tender heart, full of understanding and sympathy, and craving for affection.

Sir ROBERT JONES, Bt., K.B.E., Emeritus President of the British Orthopaedic Society of Great Britain, writes:

When the heart is full of sorrow it is not easy to pay tribute to the memory of the dead. Dawson Williams was an ideal friend—affectionate, loyal, and full of the rare gift of understanding. His acute critical faculty never dwelt on any defects in those he loved. He was the embodiment of chivalry and the soul of honour. Under a cloak sometimes austere and cynical he hid from the outside world a beautiful, gentle, and kindly nature, and a mind of refinement and extreme delicacy. What a wise counsellor to those in trouble and doubt! His guidance seemed invariably to lead to the light. One always felt safe to proceed with any undertaking if it passed his censorship. If his help was asked for he gave it whole-heartedly, and was prodigal of time and effort. He spoke his mind with no uncertain note on any question submitted to him. Friends expected nothing of him but the truth; he was guileless as a child. Nobody will ever know the weight of responsibility which he bore during the war. The Red Cross, the War Office, the R.A.M.C., and the civilian medical service at home and abroad all sought his help. He was a veritable city of refuge. Often very frail in body, his mind never lost its keen edge and his sympathy always flowed freely. When he fought, he always fought a straight fight; he never took an unfair advantage nor did an unkind thing. His death is a great loss to medicine, and his memory will be a great inspiration. For a long time past his friends knew the sufferings of his mind and the frailty of his body, but now that he has gone they realize that one of the sweetest chapters in their life history is closed for ever. Dawson Williams has fulfilled his mission and his death ends a glorious life.

Sir E. SHARPEY-SCHAFER, F.R.S., Professor of Physiology in the University of Edinburgh, writes:

The death of Dawson Williams ends for me an uninterrupted friendship of more than half a century. I call him clearly to mind as I first knew him in the seventies, a student at University College, where I was then assistant professor. He was one of a particularly brilliant coterie, all of whom made good—none better than Williams. Later he came back as a worker in my laboratory, and we were near neighbours at Elstree in his early married days, and were thus afforded opportunities for greater intimacy. I saw less of him after he had developed into the distinguished journalist whose capabilities are everywhere recognized. Few who knew him as a student would have been prepared to predict that his development would be on those lines. But the character of his writings, distinguished as they always were by clarity of description and

purity of English, might well have indicated such a destination. I have myself long been in the habit of submitting doubtful points of literature and etymology to his judgement, which was rarely wrong.

When I wrote to express the gratification I had experienced at seeing the appreciative leading article in the *Times* on the occasion of his retirement, I received a deprecatory reply exhibiting the modesty and self-effacement which were so habitual to him. "The article in the *Times* was a huge surprise to me. I never dreamed that they would take any notice of my disappearance, and that they should have done it in such a handsome way is astonishing." The rest of the letter is equally characteristic, but too intimate for reproduction. It will be one of my most treasured possessions.

Sir CHARLES SHERRINGTON, O.M., G.B.E., Waynflete Professor of Physiology at Oxford and Past-President of the Royal Society, writes:

In the death of Sir Dawson Williams I feel the loss of a friend. In the nineties of last century Dawson Williams was a frequent attendant at the meetings of the Physiological Society, and it was through them that I came to know him. To know him was to like and respect him; and although in later years opportunity did not throw us together often, yet when we met it was upon a footing such as if our previous meeting had been but the week before. In Canada once we were constant travelling companions for several days together. Railway journeying was irksome to him, and he did not conceal his dislike of it; but he was none the less excellent company. I saw him very occasionally in Oxford. He seemed to retain his interest in physiology despite the call of a career which had side-tracked him from it. He certainly preserved his sympathy with physiologists right up to the end.

Sir JOHN BLAND-SUTTON, Bt., Past-President of the Royal College of Surgeons of England, writes:

My friendship with Sir Dawson Williams began about forty years ago, when I was busy making almost daily visits to the prosectorium in the Zoological Gardens. At that date he was regularly reporting the meetings of the Pathological Society for the *British Medical Journal*. I found that rickets was a common disease of monkeys living in the menagerie, and as Dawson Williams was deeply interested in the diseases of children my rickety monkeys particularly appealed to him. He arranged with me, for convenience in reporting and for accuracy, that I should supply him with an abstract of my paper in advance, and give it to him at the meeting. This was an excellent arrangement, for in those days I was a novice in journalism. Under his skilful guidance I mastered the editorial "we," and acquired many other useful tricks incidental to successful reporting.

Dawson Williams was fond of children, and his interest in their welfare was broad and deep. Sick children have a peculiar humanizing influence on physicians and surgeons, big and little, who come much in contact with them, and especially in the intimate association of the wards of a children's hospital. Although Williams and myself travelled in different orbits—one in journalism and the other in surgery—we were often in conjunction. When he attained his altitude and his ambition, he remained the same loyal and genial friend, and, as in the early "reporting" days, he published my essays, addresses, or lectures, and gave them good places and good notices. He even allowed me in particular cases to interview the printer, so that every care was taken to do justice to Berjeau's fine drawing and Butterworth's exquisite engraving. We often met at lunch in the Garrick Club and discussed professional matters. I never heard him say an unkind word about any man. In committees at the House of the British Medical Association he listened to all that was said, rarely interfered, and always offered good advice when it was sought.

The task of editing the *Journal* is not a light one; the Editor must be wise and fair to junior members of the Association. Dawson Williams may not have been as quick as Ernest Hart, of whom Dawson Williams said that when he asked a question he divined what the man would

say before he had time to reply! Williams was a keen judge of the value of an article, a review, or a report. He told me that a weekly issue of the *Journal* contained sufficient "stuff" to make an octavo volume. A few days ago I was hunting for an article in one of the early volumes of the *Journal* and compared it with the last half-yearly volume: it was like a Book of Common Prayer compared to a Family Bible! It requires a god, like the Egyptian Toth, to hold the balance fairly in these days. Dawson Williams did it; and he leaves no small trust to his successor.

Sir ARTHUR KEITH, M.D., F.R.S., President of the British Association, writes:

The editor of a great medical journal has many opportunities of assisting in the advance of medicine; there can have been few, if any, that Sir Dawson Williams failed to utilize during his thirty years of office. His activities covered a period which was beset with editorial difficulties. The growth of medical knowledge was unprecedented, the profession became more and more divided by specialization, the ancillary subjects became more numerous and more clamorous to be heard, charlatanism in many guises sought for a place in legitimate practice, professional policy had to be shaped and reshaped, crises had to be surmounted. Sir Dawson Williams overcame all of these difficulties because he was at the core a scientific physician—one who believed that medicine could advance only by the accumulation of clearly ascertained fact and well-grounded inference. His sympathy was altogether with the inquirer and observer, the man of science—particularly the young man of science—who had something new to say. But he looked on medicine as a whole and realized that the backbone of medicine was the practising profession—the men and women who have the health of the nation in their keeping. He gathered the best that hospital ward and scientific laboratory could give him, and placed it at the disposal of his readers. He sought for, and obtained, the best that the general practitioner could give him. His wide interests in literature, history, science, and art were reflected in the pages of this *Journal*. The sixty volumes which appeared under his editorial guidance make an imposing array on our library shelves; in their pages is reflected the history of medicine of our time; they are an enduring record of sound judgement and untiring industry—such a monument as any man might well be proud of. No one ever succeeded better than he in masking activity by a show of leisure, but he was less successful in covering a warm heart by a pretence of austerity.

Sir STCLAIR THOMSON, M.D., Past-President of the Royal Society of Medicine and of the Medical Society of London, writes:

One of the many advantages of attending congresses, particularly for young men, is the opportunity they afford for making interesting, valuable, and enduring friendships. It was during the International Congress in Rome in 1884 that, by being of some slight help as an interpreter, I first became acquainted with Dawson Williams. I there noted his enthusiasm and flair as a journalist, and was still more impressed by his knowledge and interest in pediatrics, and, above all, by the evident appreciation and regard in which he was held by his foreign colleagues of the medical press. He had none of the embellishments of facile intercourse so strikingly possessed by the Editor-in-Chief of the *Journal* under whom he was then serving. Ernest Hart was suave and insinuating, and, in that way, knew everybody and went everywhere. But, as often happens amongst foreigners, Dawson Williams was sincerely appreciated because of those very characteristics which the well-read European has learned to consider typical of the British race—sincerity, transparent honesty, downrightness, and a certain bluntness both in accepting and in refusing. These impressions were confirmed during the thirty-four years which have elapsed. They re-presented themselves in various circumstances. He could accept a favour graciously, and could also decline to give one with firmness, but without wounding. During the war I formed the opinion that, like so many other people who had to carry on at home, he was overworked and, in American parlance,

"worn to a frazzle." On one occasion he told me that it was no longer "copy" he wanted, but that he did not know where to turn for printing paper and for compositors.

The welcome task of giving some help in the furtherance of a testimonial, which now, alas! must change to a memorial, has afforded me the opportunity for reading many appreciations of Dawson Williams. They have come from far and wide—Macphail in Montreal, from Cushing in the United States, from that hale and vigorous nonagenarian surgeon in Philadelphia W. W. Keen—and they are still arriving from further off. A few quotations will suffice.

"I am delighted to assist in any way I can in recognizing Dawson Williams's services to the medical profession and to science generally" (Sir Hugh Anderson, Master of Caius College, Cambridge). "I very gladly support an appeal for recognition of Dawson Williams's public services to our profession" (Professor J. S. Haldane, Oxford). "I am conscious not only of the great services Sir Dawson Williams rendered to the science and practice of Medicine, but also to the sympathy, help, and encouragement he has always extended to a young anatomist" (Professor J. S. Stopford, Manchester). "One feels compelled to respect one of the sanest and rarest minds in modern medicine" (Dr. J. S. Manson, Warrington). "He is eminently worthy of becoming an immortal" (Dr. Henry, Bournemouth). "I enclose a very small appreciation of my regard, and convey with it my great admiration for his splendid work, and to me his unflinching kindness and courtesy" (Dr. Louise McIlroy). "It will be a joy to further and support an appeal so happily conceived and so well merited" (Dr. R. M. Buchanan, Glasgow). "No officer of the B.M.A. is more worthy of esteem and recognition" (Sir John Moore, Dublin). "I trust the subscription list will show that the appreciation of his work is widespread" (Bilton Pollard). "I regard it as a privilege to be allowed to join in a demonstration of appreciation and affection to Sir Dawson Williams, to whose services we, as doctors, owe so much" (Sir Henry Gauvain).

Similar appreciations are repeated in hundreds of letters I have received. I will therefore finish with the exquisite sentence, so descriptive, in the letter of the Paris correspondent of the *Journal*. Dr. Gustav Monod, in sending his donation, writes:

"Quel bon souvenir je garderai de ce bon patron, toujours accueillant derrière ces lunettes rébarbatives." (What a happy remembrance I shall ever treasure of that good Editor-in-Chief, always with such a warm welcome behind his rather crabbed spectacles.)

Both our great medical weeklies have been fortunate in their early editors. The fiery Wakley and the scintillating Ernest Hart were the type of men to start a new adventure. Those who followed them have been the exactly necessary type to consolidate, elevate, and make worthy of appreciation those two great voices of our profession. Dawson Williams deserved well of his calling.

Sir GEORGE NEWMAN, K.C.B., M.D., Chief Medical Officer to the Ministry of Health and the Board of Education, writes:

What a man really is, in his own complex self; what he is in his home and to his own people; and what he appears to be to outside friends and acquaintances—these indeed may be three very different things. Some men have a personality which seems almost transparent, whilst in others it is concealed more than revealed. Dawson Williams belonged to the latter. I have known him for thirty years—at first at a respectful distance, as a kindly and encouraging editor to a junior and inexperienced contributor; then, in later years, he became a friend and counsellor, almost a colleague. I never saw him in his editorial room, or in his home, but we often met in Whitehall and other places, shared mutual friendships with other men, and carried on long and intimate correspondences. Only the other day I received a beautiful letter, which I shall always treasure, looking backwards and forwards, and ending with the words, "Few and obscure the days that remain to me." Now, in a twinkling, he has left us, and his large circle of friends all over the world, and the whole medical profession in England, are much the poorer.

The reason of our poverty is this. Here was a wise, competent, straightforward, and experienced man at the centre of things; one upon whom was bestowed, in exceptional degree, ability, foresight, and fairmindedness. He

was austere, hesitant, perhaps a little reticent and taciturn, inclined to aloofness, liable to be a dark horse; yes, but he was also genial and peculiarly attractive—his eyes,

"An outdoor sign of all the warmth within,  
Smiled with his lips—a smile beneath a cloud,  
But heaven had meant it for a sunny one."

And sometimes it became a very merry one, bubbling and dispersive, dissipating all over the place, lighting up a handsome face, and dispelling an anxious look which betokened mental and physical suffering. He knew the deep waters, and that knowledge left its trace in his humility and gentleness. He had met many men and reflected on the correct meaning of their words and signs, and this developed an inborn and delightful sense of humour. Yet it was upbringing and occasion which made him a humanist, gave him the chance of wielding a mighty influence, and left him in the end a single-minded man unusually devoted to duty. We can now see what he did with it all; he subordinated it to one task—the editorship of the *Journal*. It has been suggested that Dawson Williams was knighted because of his services to the R.A.M.C. I doubt it. Public recognition may be, indeed, mysterious and unequal, but my interpretation would be that when he and Sir Squire Sprigge together received the accolade in 1921, it was the official and royal sign of appreciation of their long and inestimable services to current medical literature. Comparisons are said to be invidious; but the history and contribution to medical science and humanity of the *Lancet* and the *British Medical Journal* are unique among medical papers all through the world, and the profession in this country owes more than it declares to the dignity, sagacity, and power with which they have been conducted. Their influence has been prodigious and immensely beneficial—an influence in the creation and maintenance of the profession comparable to the grand effect upon it of the Renaissance in the seventeenth century, to the brilliant work of the practitioners of the eighteenth, and to the Medical Acts and social evolution of the nineteenth. Dawson Williams's splendid innings of thirty years as Editor has played a significant part in a great constructive period. It is this achievement of his task which is surely the most impressive thing about him.

I think Dawson Williams was a Humanist. He believed in a synthetic philosophy of knowledge as well as its direct application to circumstance; he believed that the application of knowledge must have close regard to the human elements in every situation. This dual view he shared with the Humanists of the Renaissance, but he went further, because he lived in a time of social reform of which they had never dreamed. He had the broad common sense, the critical faculty, and the unifying vision belonging to the Humanist, which, with experience, gave him his supreme gift—judgement. Only last week there was a quotation in the *British Medical Journal* from Fitzjames Stephen's *Liberty*:

"The one talent which is most worth all other talents put together in all human affairs is the talent of judging right upon imperfect materials... to see things as they are, without exaggeration or passion.... All really important matters are decided, not by a process of argument worked out from adequate premises to a necessary conclusion, but by making a wise choice between several possible views."

That is what he had—a power of judgement between practicabilities. Though a philosopher in temperament, he did not write philosophy nor did he pursue a philosophic system. He took his problems very much as they came, but he tackled them philosophically, though not always patiently or serenely. He sought Reality. His religion was in that respect like the Persian Sufi: "Show me things as they really are, and not only as they appear to be." He was also an observer of the trend and tendency of events. He recognized what the Listerian revolution involved in practice; he held that a study of the diseases of children was basic; he foresaw the far-reaching changes which would follow the National Health Insurance Act and a development of the public medical services; he laboured for the reform of medical education, and particularly for the fulfilment of necessary post-graduate facilities; above all, his belief in medical progress in England found alike its rational basis

and its confidence in the medical practitioner. Here five visions which he saw and noted, for he was not only observer, but a recorder. Thus it would seem that place of Dawson Williams in modern English medicine that of *humanistic recorder*. The last discussion we together was upon this theme of Doers and Recorders. I described a certain medical contemporary as a Doer, who himself was only a Recorder; one, he said, makes history the other writes it. Yet for the majority of men history does not become inspiring or directive until it is recorded. Dawson Williams knew that from such record advances spring, a spell of recording being followed by a period of new doing. The doer is, of course, the creative, the explorer, the thinker, the transmuted Leonardo, Harvey, Hunter, Jenner, Pasteur, Lister—the recorder is the *transmitter*. As the art of printing was an essential implement of the Renaissance, so great journalism is the active instrument of progress to-day.

As Dawson Williams pursued this high road he found his journey dusty. But he was a good and courageous traveller, and knew the dangers of the way. Highwaymen had short shrift—doctrinaires, quacks (qualified or otherwise), humbugs, chatterboxes, pretence, advertisers, and downright robbers all "got it in the neck" sooner or later. Some he scoured with satire, the delight of passers-by; others were shot dead—to the satisfaction of all honest men. There were, again, more subtle dangers which he also knew—the sloppy work without meaning, the unsupported generalization, the sanguine hope, the fully presented but unproved case, the much announced panacea. Against these allurements all he had his own defences. When he travelled by daylight he was accompanied by a retinue of many devoted friends, by whom he was greatly beloved; when he travelled in the darkness he found his way by the light of a lamp within.

Sir SQUIRE SPRIGGE, M.D., allows us to quote the following passage from the memoir that appeared in last week's *Lancet*:

"Austerity and gentleness, ability, and fairness were expressed in his actions and words exactly as each was demanded. These qualities were reflected throughout his conduct of the *British Medical Journal* and also in his dealings with members of the medical profession, a countless number of whom must owe him a debt of gratitude for counsel and assistance. Among such is the present Editor of the *Lancet*, and he and all associated with him in the conduct of this paper feel the death of Dawson Williams a personal loss. We trust that similar feelings, widely evoked in the medical profession, will express themselves in the movement started just before his death to create a tangible memorial to him."

Sir D'ARCY POWER, K.B.E., consulting surgeon to St Bartholomew's Hospital, writes:

To lose one's early friends is the penalty of age, and the circle becomes smaller every day. On February 14th Sir Dawson Williams was taking part in the Hunterian festival at the Royal College of Surgeons. We were speaking before dinner of those early days of struggle which are so pleasant in the remembrance—days when he was an assistant physician and I an assistant surgeon attached to hospitals for sick children; both active members of the Pathological Society, to which we brought specimens and where we had those active discussions which are no longer common at medical gatherings. Both of us, too, were keeping our heads above water by devilling for Ernest Hart, a past master in the art of extracting "copy" from those he was accustomed to call his young men—"copy" in the form of articles or abstracts often demanded at a moment's notice, and criticized by a somewhat caustic tongue. At that time Dawson Williams was in the fairway of success as a consulting physician, and it was some matter of wonder to us that he gave up practice and chose journalism as a profession. But *respicere finem*, he was *primus inter pares* as a medical editor; as a consulting physician he would only have been one amongst many.

Dr. HERBERT SPENCE, Consulting Obstetric Physician to University College Hospital, writes:

The sudden death of Dawson Williams came as a severe blow to his friends, who were hoping that he would live for many years to enjoy his well-earned rest. Having had his intimate friendship for thirty years I should like to add a few words to those of others; for I think he was known intimately to but few, and his somewhat austere and troubled countenance and reserved manner hid from the multitude his real worth and affection and his sense of humour. He had the true north countryman's desire for facts—"chiefs that winn ding"—and for honest statement. He wished everything to be "jannock," though I never heard him use the word. Though fluent with his pen, he was sparing with his voice, except when indignation stung him to very effective speech.

Dawson Williams had the honour of the profession and the welfare of the Association as his constant interests, and was always alert to bring new facts before the profession. I may mention that when Wertheim in 1905 wrote his great paper on extended abdominal hysterectomy for cancer Williams undertook to have the German MS. translated and published in full in the *Journal*, and from that time the operation became widespread in Great Britain. Williams also took great interest in the development of the radiation treatment of cancer, and, indeed, in all obstetrical and gynaecological subjects. I have often been admitted to his editorial sanctum and watched the rapid and effective way in which he conducted the business of the *Journal*. He often spoke to me in terms of praise of his subordinates—behind their backs—and from their attitude I could see that they, like all who knew him intimately, understood, trusted, and admired their old chief.

Since his retirement Dawson Williams was occupying himself in preparing an account of the forthcoming Harvey tercentenary celebrations. A few weeks ago he went down to Hempstead Church, in Essex, with some friends to examine the Harvey monuments. He lunched with those friends, who arranged to meet him again at dinner on the very day of his death. His sudden death has saddened them, but they will retain a fragrant memory of him as a great journalist, a pleasant companion, and a dear friend.

Dr. ARNOLD CHAPLIN, Harveian Librarian of the Royal College of Physicians of London, writes:

The great work of Dawson Williams during the many years he occupied with such distinction the editorial chair of the *British Medical Journal* will receive adequate recognition in the biography which appears this week. His great ideal was to perform his duty no matter what the cost might be; and how much the attempt to accomplish this ideal cost him during the last five years of his life, with failing health, no one will ever know. Although his work for the *Journal* was ever his chief care, it did not prevent him from taking a deep interest in other matters. Among these was his love and veneration for the Royal College of Physicians, and he probably valued his election to the Fellowship higher than any of his other distinctions. He was a constant attendant at the meetings of the Comitia, and hardly ever missed the Comitia dinner in the evening. Here he was at his best, surrounded by his friends and enjoying himself to the full. For many years he was a member of the Library Committee at the College, and this position brought him into contact with books, for which he always had an abiding and deep love. He was a widely read and cultured man, and when "off duty" and at his ease few could be more engaging and interesting. Of his great moral qualities it is unnecessary to speak, for his honesty, his firmness, his perseverance, and his kindness of heart were well known to all with whom he came into contact.

Professor W. E. DIXON, M.D., F.R.S., writes:

With the death of Sir Dawson Williams a great man has passed away. His sentiments were mainly those of benevolence, and his aspirations for helping the helpless, and in his medical outlook his special sympathies embraced all that pertained to treatment. As an editor he was unique: his studies were wide, his acquaintance with books great, and what he did not immediately know he could at least

tell where to find. Most men readily accept the praise given them, and regard the sentence in their favour as a sign of acumen; but blandishments were entirely wasted in Dawson Williams's office and, beyond a twinkle, evoked no response. His literary judgement was severe, but, having decided to accept a paper, I have known him take infinite pains to put the writer's meaning into understandable English. As a writer Dawson Williams had the perspicacity and elegance of the historian; his precepts were judicious, often now, and always happily expressed.

Dawson Williams was really interested in science; often he would sit through a meeting of the Physiological or other scientific Society and afterwards discuss the validity of the evidence of some young man who had expressed a new idea. I knew him very early in my career; he was always open to new ideas and never received suggestions from his juniors with derision or contempt. His sympathy he extended to all, but to hold his friendship was a prize; he seemed intuitively to read thoughts and difficulties, whilst his knowledge, not only of literature, but of men and matters, was of the widest. As his years advanced he advanced in reputation, but his mind, always richly furnished and adorned, and arranged in the most regular order, seemed to become even more alert; in his latter years oftentimes he was distressed at making decisions likely to cause pain.

Socially, Dawson Williams was delightful; his active and inquiring mind showed itself in the vigour of his colloquial wit. Nothing he enjoyed more than to sit after lunch in the Garriek with two or three literary friends, with a good glass of wine and a cigarette—for Dawson Williams, like most of the great in literature, knew how to get the most and best out of life. He was a man of great liberality and dignity of sentiment, with little ambition and no vanity. He is gone—this great literary critic, this kindest and most lovable of men, whose goal in life has been to help those in pain or difficulty.

Sir C. J. MARTIN, C.M.G., F.R.S., Director of the Lister Institute of Preventive Medicine, writes:

May I add my note to the chorus of appreciation of our friend Dawson Williams? No one, unless he has served on the Council and some of its numerous committees, can appreciate what we owe to Dawson Williams for his skilful conduct of our *Journal* and the sanity of his influence upon the policy of the Association. He never failed to realize that the British Medical Association was something greater than a professional corporation to safeguard the interests of its members, and that its equally important function was to encourage medical discovery and spread knowledge amongst its members.

I have referred to his conduct of the *Journal* as skilful. That adjective is inadequate to describe his editorship. Skilful handling was essential, but Dawson Williams brought greatness of purpose to this, his life's work. He knew that if the *B.M.J.* was to maintain its reputation as a leading organ of medical thought it must be, not merely a professional newspaper, but reflect in its pages the progress of medical knowledge and scientific discovery. Dawson Williams, who was equally interested in the science of medicine and its application, and equally capable of comprehending both, was especially qualified to make the adjustment between science and practice, and eminently successful in keeping the ship on an even keel. The editorial chair of the *B.M.J.* is, in some respects, a peculiarly difficult one. All editors have their troubles with their proprietors, and in his case there were 33,000 of them! It is impossible to please everybody, and if the scientific side of medicine has been less emphasized than he and some of us desired, that must not be attributed entirely to the appetite of the members of the Association for records of cases and accounts of successful treatments. Original scientific papers are "bad copy," as they generally describe but bricks in an edifice, and only interest the builder. Many are unnecessarily tiresome. I remember on one occasion, when urging the devotion of more space to dealing with the growing edge of those sciences on which the practice of medicine is based, he replied, "If you would write intelligibly I would publish," and the remark was not intended, I believe, to apply to myself exclusively.

As its Director, I desire to add a few words of grateful recognition of Dawson Williams's service to the Lister Institute. By the constitution of the Institute, the B.M.A. has a representative on its Council, and although the Council has no longer executive responsibilities, it has some important duties. For many years the Association was represented by Ernest Hart, who was one of the founders of the Institute. Subsequently, when Dawson Williams was nominated, the staff were more than pleased, for, remembering his keen interest in the work of Pasteur and Lister, and the contribution he made to the spread of knowledge of Pasteur's work by translating his more important papers, they were sure of his understanding and sympathy. For eighteen years Dawson Williams manifested a helpful interest in the work of the Lister Institute, and was a constant attendant at its meetings. On other occasions, too, his advice was sought and ungrudgingly given. His fellow councillors will deplore the absence of a colleague on whose wisdom they relied, and the staff of the Institute, one and all, know that they have lost a very good friend.

Dr. C. O. HAWTHORNE, Chairman of the Representative Body of the British Medical Association and Acting Chairman of Council, writes:

Those of us who for a number of years have had close personal and official relations with Sir Dawson Williams have difficulty at this moment in expressing any thought other than the sense of loss which has so suddenly fallen on us. But a few weeks ago we said regretfully a formal farewell to an editor and a colleague, but we said it with the full hope that for him time had many restful hours in store, and for ourselves opportunities for renewals of friendship and of counsel. And now, as it were in a moment, all these pleasing anticipations close in darkness and, in some sense, in dismay; for, behind his apparent severity and aloofness, Dawson Williams had for those who served with him a large capacity for comradeship, and qualities which stirred and held affection; not readily known perhaps, but well worth knowing, and genuine and real and sincere. One might differ from him in opinion, but no one questioned his integrity, and these personal qualities gave him the secure position which he held in the esteem and regard of his colleagues. With his resignation of the editorial chair there was a not unnatural conclusion that his work was done, but many of us who have been close to his stores of knowledge and experience and goodwill were counting with confidence on not a few helpful associations in the future. The editorship indeed had ceased, but not, we knew well, the friendship and the readiness for service. Now fate has put its seal on both chapters, and left us but memories and regrets.

In this brief note of appreciation I must recall general impressions rather than particular incidents. These come from associations, enterprises, and responsibilities shared in a common, but not an equal, partnership; for with all his knowledge and experience Williams was always ready, and indeed anxious, prior to decision and action, to hear the other view. He was, too, a good listener, and patient of the other view—at least to a point—and he would take it from anyone so long as arguments could be quoted in its support. But beyond this moment the caller, apparently from some mysterious change in the atmosphere, became aware that the editorial time was valuable, and that the last word had been said. In his own department he refused to be hurried in judgement, but he was not afraid of decision, and he preached and practised the doctrine of editorial responsibility in no uncertain fashion. Not unnaturally he took a high view of the function of the *British Medical Journal* in the scheme of the Association and, indeed, in the work of the profession generally, and against anything which tended to lessen this claim he was prepared to offer a strenuous resistance. Here, he would urge, is post-graduation training brought to the practitioner's door. Nor were his sympathies by any means restricted to the editorial chair. On the contrary, he was alert to all the interests and enterprises of the Association, and was keen to hold these to the highest standards. In council he was helpful with information and a certain spaciousness of judgement, and though cautious, he would press the bold view where his convictions were strong. Perhaps he accepted

rather grimly an adverse decision, but he had a high sense of loyalty to the Association, and happily he cultivated a generous measure of humour which leant rather to the ironic side. To be associated with him in the work of a great organization was to learn with what abundance of knowledge and experience his mind was equipped, to grow an increasing regard for his high sense of personal and professional rectitude, and gradually to recognize that a great editor was none the less a man and a brother.

Mr. N. BISHOP HARMAN, F.R.C.S., Treasurer of the British Medical Association, writes:

To die in harness, time-worn, tired, but still striving, is given to few of us. But this has been the lot of Dawson Williams. The days since his retirement are too few to count the interval. The pages of the *Journal* that he has penned are still alive; his words spoken at the committee meeting still ring in our ears; and his last letter, written only a few days ago, still shows that his mind turned on new work even in retirement.

Dawson Williams left his impress upon everyone who came into contact with him. There is fresh in my memory the first time I met him in person. The "Editor" I had heard of: it was Dawson Williams I met, and felt. I had gone to put a piece of information before an impersonal editor: I met a person—a man tall of stature, keen-eyed, and slow of speech. He took me into an adjoining room, introduced me to his shorthand writer with the words: "This member will dictate an article to you." I felt like a small boy at school before a great, compelling, and all-pervasive headmaster. Dawson Williams was like that; he made one feel his mastery of things. He combined within himself the playful attitude of the father of the family and the shrewdness of the headmaster. All his contributors felt they were members of his family, sons who could trust his direction, no matter how much they might be inclined to rebel against his mastership. Each of us felt his breadth and weight of knowledge, sometimes with surprise that he had his eye upon our little corner of medical work. But he was kindness personified. Our glittering gems that we spread before his shrewd eyes were appraised with gentleness and fairness, and if their lustre seemed to dim somewhat in our own eyes after his hint of some needed change in the setting, at least we saw his fairness, and withal the kindness of his dealing. But Dawson Williams filled a far larger part than that of a great editor. In the last few years, when, as Treasurer of the Association, one came nearer the focus of medical affairs, especially those pertaining to the Association, the greatness of his counsellorship could be realized, and with that came a better appreciation of the greatness of the man. His single-eyed devotion to duty was manifest. No matter whether the subject for consideration was the exposition of the progress of the healing art, or whether it related to some delicate piece of negotiation, or the solution of an inevitable problem the fruit of our complex civilization—for either the one or the other his attention was unfailing and his judgement of worth. He did not fail even in the last years, when weakened physical strength would have excused some relaxation in any man. With him will-power was stronger than aches or pains.

The passing of Dawson Williams leaves a sense of great loss. Something—no, someone—has gone out of things. There is one fewer of those tried and trusted counsellors whose influence is like the great tide that floats the laden vessel along with steadiness and certainty. But the memory of the man remains, unforgettable.

Dr. J. A. MACDONALD, LL.D., who, as Chairman of the Representative Body, Chairman of Council for ten years, and Chairman of the Journal Committee since 1920, was intimately associated with the Editor, writes:

Dawson Williams died on February 27th, and so passed one of the great figures in the medical world of the past half-century. He was great in many respects. In his personality strong, logical, impartial, always willing to give full value to his opponent's position; reserved, but when his outer shell of shyness and reserve was penetrated there was found a person of essentially sound sense and a wise counsellor. He was great in his profound

knowledge of the medical literature of all nations. He was great as a medical journalist—in my opinion he was the greatest medical journalist of his time. It was in this role that he found his life work—the control and development of the *British Medical Journal*. He gave up his life to this work and reaped his reward in seeing the *Journal* attain its present proud position of the leading medical journal in the world. He was perhaps greatest in the influence he brought to bear in furthering the highest interests of the medical profession and of the British Medical Association. I think very few, even of the members of the B.M.A., are aware of the influence Dawson Williams, by his own personality and through the *Journal*, exerted in the development of the policy of the Association, particularly in keeping it on sound and dignified lines. His influence in all things relating to the profession was always on elevated lines; he had an intense sense of the dignity of medicine as a profession.

It is one of my proudest memories that for twenty-five years I was more or less closely associated with Dawson Williams in my many official positions in the British Medical Association, and, in later years particularly, as Chairman of the Journal Committee. As a personal note may I say that with the passing of Dawson Williams has passed out of my life the one among all men for whom I had the highest respect and esteem. He has deserved well of the profession he loved and adorned.

Sir ROBERT BOLAM, M.D., LL.D., Chairman of Council of the British Medical Association, 1920-27, writes:

A man must have certain qualities successfully to conduct a scientific journal, and yet others if his task be the editing of a journal of news and of policy. In rare degree Dawson Williams combined scientific insight and wide general learning with journalistic intuition and that faculty of analysing men and affairs which needs must go to the framing of sound policy. He had a wide field of interest and influence within the profession, and in many unexpected quarters outside of it. In argument and expression he was master of many styles and gave to none, whilst few men have attained more nearly "the chief of all perfections—to be plain and brief."

One has heard it said that Williams was not an easy man to know. Truly he had a mantle of reserve, yet it was but the garment of his office. This cast off, one found a quick and lively spirit, generously helpful to all seekers of counsel, specially tender to the inexperienced, impatiently scornful of the futile, the mean, the mercenary; revolting fiercely in face of things wrong or unjust. All his insurgent tendencies he ruthlessly schooled to serve his one great end, the welfare of his beloved *Journal*. And though

"When the lamp is shattered  
The light in the dust lies dead,"

there remain to us his ideals of service—to heed no faction, to fear not in right seeking, to spare not self.

Sir JAMES BARR, C.B.E., M.D., who was President when the British Medical Association met in Liverpool in 1912, writes:

The sudden death of Sir Dawson Williams must have come as a great shock to those who were not aware of the serious condition of his health; yet even to his intimate associates the suddenness of his demise must have been quite unexpected, and no one anticipated that the testimonial which was recently launched in recognition of his long and valuable services to the medical profession would have to be turned into a memorial; such are the ups and downs of life, and no one knows what a day may bring forth. It is true that his "day's work" was done; he had just retired from the arduous and onerous duties of an exacting office, with the plaudits of the Association which he had so long and faithfully served. Every member of the British Medical Association can truthfully say, "Well done, good and faithful servant; enter thou into the joy of thy Lord"; but there is no one who will not shed a tear

over his departure; everyone will miss his genial presence, and regret that he has not had an opportunity of viewing life from a disinterested standpoint. I was on the Council of the Association when he succeeded Ernest Hart, and consequently I have known him during the whole of his editorial career. His urbanity endeared him to everyone, and he always retained his popularity, even with those who did not approve of the frequent changes of the policy of the Association. Death has taken him from us, but in the memory of everyone who knew him he will long live. In life he was a burning fire which kindled many a hearth, the bright effulgence of which will not soon be allowed to die out.

Dr. ALFRED COX, O.B.E., Medical Secretary of the British Medical Association, writes:

I find it nearly as difficult to write about Dawson Williams as it was for me to get to know him. I have been in contact with him for thirty years, and for the last twenty have been his colleague; but for a long time I thought him unapproachable and *difficile*; one did not seem to get much nearer to him on the occasions on which we met, and it seemed to be necessary every time to reopen the path of approach. It is only in the last eight or ten years that I have felt we were on easy and companionable terms. At first I found him formidable and austere, and (I thought) not very sympathetic to my special anxieties and difficulties. This was particularly during the stormy times of the Insurance Act, when there was so much division of opinion inside the Association. I recognized, like everybody who came in contact with him, his sound judgement, his honesty of purpose, and his unshakable integrity as a man and a journalist; but I did not make sufficient allowance for the fact that his duty as an editor compelled him to look at things and write about things from all angles. But I learnt much from him, and always admired him immensely, and in time his devotion to the Association, his gifts of intellect, a certain mellowing of demeanour, and the knowledge one got (but never from him) of his great domestic anxieties, broke down the barriers between us, and I learnt to love as well as to admire him. He set a standard of work for all of his colleagues which we humbly, however unsuccessfully, try to attain, and I think he was pleased when, on behalf of the rest of us, I had the privilege of saying so at a little dinner we gave him when he retired. He hated anything like gush, but on that occasion I believe we did get him to feel our absolute sincerity when we told him how much we admired him and his work, and how proud we should feel if, when our turn came, the Association could as truthfully and as forcefully say, "Well done, good and faithful servant."

In the various appreciations of our old friend I have not seen any reference to his gifts as a speaker. Among the many things he disliked was having to make a speech in public, and he would do a good deal to avoid it; but I have known few men more effective when he did rise to speak. His choice of words was, of course, admirable, and before his health failed his manner was equally good.

The Association has lost a great Editor, and we of the staff a colleague of whom we were very proud. May he rest in peace.

Mr. W. E. HEMPSON, who is retiring at the end of this month from the position of Solicitor to the British Medical Association after thirty years, writes:

It was a real shock and grief to me to read of Sir Dawson Williams's death. I have before me a letter from him, on which the ink is scarcely dry, in which he writes of "our long collaboration in the work of the B.M.A. We have witnessed, and each in our way shared in, its development." My close relationship with him extended well over thirty long years without a break on either side. I can therefore speak with appreciative knowledge of his sterling qualities as a man, and also as a light in the world of literature. To have enjoyed his confidence—which he was slow to give—was a privilege of which one may well feel proud, and the lighter side of his character was only revealed to those who were thus accepted by him.

Sir ANTHONY BOWLBY, Bt., K.C.B., K.C.V.O., Past President of the Royal College of Surgeons of England, who was Advisory Consulting Surgeon to H.M. Forces in France throughout the war, writes:

May I send a very few lines to recall to mind the very great service rendered by Dawson Williams to the medical service of the Army and the Navy? Whoever might have been responsible for the mobilization of the fighting forces of the Crown, there can be no doubt that the mobilization of the medical profession was the work of Dawson Williams. To further this end he laboured without ceasing, and his thorough knowledge of the members of his profession, and his sympathy and common sense, enabled him to do work which was of the greatest service to the soldiers and sailors of Great Britain.

Lieut.-General Sir ALFRED KEOGH, G.C.B., G.C.V.O., who was Director-General, A.M.S., in 1904-10, and again in 1914-18, writes:

May I be permitted to associate myself with the many who will have heard of the death of Sir Dawson Williams with the most profound regret? I have the more reason for this regret in that I owed to him at times of great difficulty much wise counsel and an abundant sympathy. He was ever gentle in his criticisms and a trustworthy guide at all times, ever ready when I had recourse to him, which was often, to smoothe the numerous difficulties which frequently arose. I owe to his memory a profound respect, and I sorrow to think he is no longer with us.

Lieut.-Colonel D. G. CRAWFORD, I.M.S. (retired), the historian of the Indian Medical Service, writes:

The British Medical Association has always done much for the public medical services, the Navy, the R.A.M.C., and the I.M.S. As regards the last, many of those who have spent their lives in the Indian army have always realized what a debt of gratitude they owe to the Association, and in particular to the late Editor. Some of them, like Kenneth Macleod and Walter Buchanan, have preceded him across the great divide. One of those who remain may perhaps be permitted to express here that gratitude to one who has just completed a life's work—a long and full life's work, well and thoroughly done; one of whom it may truly be said *Felix opportunitate mortis*.

Dr. F. E. FREMANTLE, F.R.C.P., F.R.C.S., M.P., writes:

As Chairman of the Parliamentary Medical Committee may I add a tribute of respect for Sir Dawson Williams on the part of my colleagues and myself? During the last nine years he developed the parliamentary side of the *Journal* with great success. The "Medical Notes in Parliament"—reprints of which are sent weekly to every medical member of Parliament—have become more and more a sure and useful record of medical events and opinion at St. Stephen's. The editorial work has always expressed a wise and sober judgement, wide sympathies, and a bold imagination. It was but a short time ago that he urged me in person and by letter to explore further a certain system of preventive treatment which had been rejected by a Government department on what seemed to him insufficient grounds. On each question of medical interest, as it drifted across the public screen, he was ready to hear opinions from every quarter; but was not slow to focus them into place and to draw the proper conclusion, leading to effective action. When the interests of the medical profession might seem at first sight to clash with those of the public, Sir Dawson Williams served both with the most convinced loyalty; the loss to the profession by his death is so much the greater. We mourn the passing indeed of a great leader as well as a personal friend.

Dr. DAVID NICOLSON, C.B., LL.D., formerly Lord Chancellor's Visitor in Lunacy, writes:

I shall be glad if I am permitted to offer my testimony to the high regard in which, with many others, I hold the memory of Sir Dawson Williams with respect to his work and his personality. I always found him pleasant and agreeable and ready to oblige, and he stood the pressure of his work with wonderful equanimity.

Dr. J. S. MANSON (Warrington) writes:

As a general practitioner who has occupied from time to time some of the *Journal's* space, let me pay tribute to the patience of the late Sir Dawson Williams and to the kindly help which he gave to an inexperienced writer. I have no doubt that similar help has been given to many others, and it would be a pity if at this time no mention were made of this fine trait in his character. He also was concerned greatly with the continued education of the general practitioner, and was proud of his work in improving the Library to help forward that aim. I have a letter from him, dated December 23rd last, where he mentions his interest in the improvement of the Library of the Association, and expresses satisfaction with its present success. It is said that without vision the people perish. Sir Dawson strove to give vision to the ordinary practitioner, who in his tens of thousands forms the main body of the profession.

Our correspondent in France, GUSTAVE MONOD, M.D. Paris, M.R.C.P. Lond., writes:

Dear Sir Dawson Williams! Such a loss will be deeply felt all over the world, and first of all in France, where his influence has been far beyond what he would ever admit. It was difficult to find in the *Journal* the name of the Editor; but every page was inspired by his spirit, and his friends never hesitated to recognize "la griffe du Lion" in the editorial columns. I am told by a Paris medical librarian that the *British Medical Journal* collection is in constant demand by his readers, and no doubt the indomitable effort of Sir Dawson has gone very far to bring British Medicine to its high international acknowledgement. He leaves a last example of incessant work, and it is, in the name of French medical journalism, to him adieu, in the name of French medical journalism, to him who has always proved to be *le bon Patron*.

We are glad to print the following note from an old and valued contributor, if only because it brings out a side of Sir Dawson Williams which meant very much to his colleagues in the Editorial Department.

May a tribute ("H. C." writes) be permitted from a lay journalist whose miscellaneous "copy" came under the great Editor's pen for a space of twenty years? In the great Editor's pen for a space of twenty years? In the matter of style he was an austere man, not the easiest of editors to please. The ways of some writers annoyed him excessively. He was intolerant of "fine writing"—writing which had every merit except that it did not clearly and conscientiously convey ideas; it was part of his general impatience with everything affected and unreal. On reading over my "copy" after it had left the editorial mill, I often had occasion to deplore that many smooth sentences had now been given a jagged edge, and that some picturesque similes and allusions had vanished altogether; but I was bound to admit that the Editor's touch, if it had not adorned, had clarified the writing. On the other hand, the Editor had rather a fancy for unusual words, and liked also the terse epigrammatic title; I was rather amazed to find some bold ventures of my own in this direction accepted. And who that ever wrote for him can forget his exigencies—the grim smile with which he would hand over a mass of inchoate material with a request that "copy" be delivered at once or sooner! His criticisms could be delivered at once or sooner! If there was a weak point in an article or report, spun over by a web of words, he detected it unerringly. The sharp criticism stung, but it was salutary. He could praise on occasion, but he rather followed the plan of the late Lord Salisbury, who, it is said, always flavoured his praise with a little qualification, lest the son of the recipient should be harmed. But if the Editor himself made a misjudgement regarding a contributor no one could be more humble in apology. In many ways he was most indulgent. Frailty he could pardon, it was pretension he found it difficult to forgive. It is sometimes realized how vast a front every issue of a journal offers to microscopic criticism on the ground of accuracy; but this Editor concealed his own vexation at the necessity of this Editor concealed his own vexation at the necessity of printing errata, upheld his contributor if he thought him in the right, and did not "rub it in" if he was evidently wrong. There are not a few journalists on whose style and

method Sir Dawson Williams exercised a stimulating influence, and who will ever hold him, as a master of their craft, in grateful and admiring recollection.

#### FUNERAL AND MEMORIAL SERVICE.

The funeral was at Little Marlow Cemetery near Sir Dawson Williams's country home at Well End, Bourn End-on-Thames, on the afternoon of Friday, March 2nd. Those who stood at the graveside with relatives and family friends and neighbours included the Treasurer of the British Medical Association and Mrs. Bishop Harman, Mr. W. McAdam Eccles (Chairman of the Hospitals Committee); Sir Squire Sprigge (Editor of the *Lancet*) and Lady Sprigge, Mr. E. Muirhead Little, Dr. and Mrs. Henry Devine, Dr. Alfred Cox (Medical Secretary), Dr. N. G. Horner (Editor), and Mr. L. Ferris-Scott (Financial Secretary and Business Manager); with Mr. Stephen Morrey (Head Clerk of the Editorial Department) and Mr. Trevor Lapworth (Head Printer), who were closely associated with our late Editor in his work, one for forty-six and the other for forty-four years.

A memorial service was held on Monday afternoon, March 5th, at St. Pancras parish church, close to the headquarters of the British Medical Association. It was attended by a large gathering, which included many distinguished and representative members of the medical profession, some of whom were present in an official capacity.

The President of the British Medical Association (Sir Robert Philip), with the principal officers and officials, and many members of Council attended; other members of Council sent expressions of regret for their absence. A group of representatives, headed by Sir John Rose Bradford, came from University College, London, and University College Hospital Medical School. The Royal Society of Medicine, the Medical Society of London, and other professional bodies joined in the tribute through their presidents or other officers. From the headquarters of the Association, over which the flag flew at half-mast during the day, came practically the whole of the staff, from the heads of the departments down to the most junior employee. It was pre-eminently a gathering of the late Editor's colleagues—men and women who had served with him and under him, some of them for more than a generation, and to whom the occasion brought an added sadness because so short an interval separated it from the official parting from their chief.

The Vicar of St. Pancras (Prebendary E. L. Metcalfe) conducted the choral service, which was marked throughout by a fine simplicity such as the man it commemorated would have desired. There was no address, no laudatory oration, only the familiar phrases and the sublime music—the latter including the anthem "O rest in the Lord," to Mendelssohn's setting, and the Funeral March by Beethoven. But when the President of the Association went to the lectern and read with much feeling the well-known passage from the Book of Ecclesiasticus beginning "Let us now praise famous men," some of the sentences in that familiar eulogium seemed to have a startling significance:

"... such as did bear rule in their kingdoms and were men renowned for their power, giving counsel by their understanding, such as have brought tidings in of the people by their counsels and by their learning for the people—wise were their words."

The twenty-third Psalm was chanted, and then followed the usual litanies and petitions, one of the latter being the Thanksgiving in the present burial service, while two others—one of them for peace to the departed and the other for comfort to those who mourn—were taken from the permissive use of the Revised Prayer Book. The prayers concluded with the fervent sixteenth-century petition, "O Lord, support us all the day long of this troublous life." The hymns chosen were also those hallowed by long usage on memorial occasions—"Fight the good fight" and "O God, our help in ages past." The congregation dispersed, and work was resumed at headquarters in the spirit of the majestic words from the Apocrypha which had been read:

"Their bodies are buried in peace, but their name liveth for evermore."

The following were among those present:

Mrs. Hill (sister), Mrs. Arthur Williams (sister-in-law), Sir Robert Philip (President of the British Medical Association), Dr. O. O. Hawthorne (Chairman of Representative Body and acting Chairman of Council), Mr. Bishop Harman (Treasurer), Sir Robert Holam, Dr. Barcroft Anderson, Dr. F. W. Goodbody, Mr. W. McAdam Eccles, Dr. R. Langdon-Down, Dr. Christino Murrell, Lieut.-Colonel F. O'Keefe, Mr. H. S. Souttar, Mr. E. B. Turner, and Sir Jenner Verrall (members of Council), Mr. Walter G. Spencer (Honorary Librarian), Mr. W. E. Hempton (Solicitor to the Association), and Mr. W. E. Warne (late Financial Secretary).

Sir John Rose Bradford, President of the Royal College of Physicians, who also represented University College, London, together with Sir Gregory Foster (Provost), Professor Elliot Smith, Mr. Douie (Secretary), and Mr. Gwynno Williams, representing University College Hospital Medical School.

Sir Outhbert Wallace, member of Council, and Mr. S. Forrest Cowell, Secretary of the College of Surgeons of England; Sir Charles J. Martin, representing the Council of the Lister Institute, and Dr. H. H. Dale (Secretary of the Royal Society), representing the Medical Research Council.

Sir George Newman (Chief Medical Officer, Ministry of Health), Sir Humphry Rolleston, Sir Charles Ballance, Sir D'Arcy Power, Sir George Halkin, Dr. F. E. Fremantle, M.P., Dr. Herbert R. Spencer, Dr. William Hunter, Professor W. E. Dixon, Dr. Charles Buttar, Major-General J. B. Smith, representing the Indian Medical Service, Colonel Batyze, I.M.S., and Mr. L. Muirhead Little.

Sir Squire Sprigge, Editor of the *Lancet*; Dr. Violet Kelcnack and Mrs. Bolton, representing the Medical Women's Federation; Mr. G. S. Elliston, representing the Society of Medical Officers of Health; Dr. James Neal, representing the Medical Defence Union.

Dr. Arnold Chaplin, Dr. Canace Wilkinson, Dr. and Mrs. Bernard E. Potter, Dr. Percy Spurgeon, Dr. S. Gilbert Scott, Dr. Herbert W. Nott, Mr. H. Outhbert Dixon, Dr. and Mrs. J. W. McNeer, Mr. Bertram Sutton, representing the Medical Sciences, Anatomy, and Life Assurance Society; Major Eden Paget, representing the Home Service Ambulance Committee of the Order of St. John and the British Red Cross Society; Mr. J. W. Wharton, representing the Garriek Club; Dr. Rawlins, Dr. Viney.

Dr. H. LOVETT CUMMING, who died at Shanghai in January, was born in Glasgow in 1878. He was educated at Merchiston Castle and George Watson's College, Edinburgh, and subsequently at the Edinburgh University, where he graduated M.B., Ch.B. in 1902, proceeding to the M.D. with commendation in 1905. He obtained the D.T.M. and H.Camb. in 1916 and D.P.H. in 1917. After holding several appointments, including those of house-physician and pathologist at the Prince of Wales's Hospital, Tottenham, and house-physician to the Royal Chest Hospital, London, he practised in South-West London until his departure in 1910 for the Far East, where for five years he was medical officer to various groups of rubber estates in Johore and Malaya. In 1915 he became a temporary lieutenant in the R.A.M.C., and served at the Fulham Military Hospital. He went to Hong-Kong in 1918, and after remaining one year there proceeded to Shanghai, where he set up in general practice and became visiting physician to the Shantung Road (Chinese) Hospital. Dr. Cumming was a member of the Mid-China Branch of the British Medical Association.

By the death, on February 2nd, of Dr. JOSEPH WILLIAM GILL of Rilla Mill, that section of South-East Cornwall has lost a man of outstanding personality. Born in 1866 at Croydon he received his medical education at the Middlesex Hospital, obtaining the diplomas M.R.C.S., L.R.C.P. in 1888. In 1895 he took the diploma D.P.H.Lond., and in 1906 he graduated M.D.Durh. He went as assistant to Dr. W. Nettle of Liskeard in 1890, being also appointed medical officer to the Phoenix and other mines. In the Boer war Dr. Gill acted as medical officer at concentration camps, but contracted typhoid, and was invalided home. During the late war he held a commission as captain in the R.A.M.C., working on hospital ships travelling across the Channel until incapacitated by illness. He served under the Local Government Board on a commission to inquire into conditions of British workhouses, and was at one time district medical officer to the Liskeard Board of Guardians. Dr. Gill took a great interest in the history and antiquities of the county where he worked for so many years, and was associated with the Royal Institute of Cornwall. He had travelled in the Far East also, and had a wide outlook and understanding of questions relating to the Empire. He remained a member of the British Medical Association until the end of last year, when his final illness compelled him to give up the greater part of his professional activities. He married in 1897, and is survived by his wife, a son, and a daughter.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

IN the House of Lords, on March 6th, the Public Health (Destruction of Vermin) Bill was introduced by Lord Strathspey, and read the first time.

The Army Estimates were introduced and debated in the House of Commons on March 8th. On March 5th the Reorganization of Offices (Scotland) Bill was read a second time. Mr. Chamberlain presented on March 6th a bill to extend the duration of the Local Authorities (Emergency Provisions) Act, 1923, and to amend temporarily the provisions of the Metropolitan Common Poor Fund. The bill was read a first time. A bill dealing with hours of closing in shops was debated on March 9th. The other business of the week was of minor importance.

A meeting of the Parliamentary Medical Committee was arranged for March 6th.

### Tetra-ethyl Lead in Petrol.

IN the House of Lords, on February 29th, Lord BUCKMASTER opened a debate (briefly summarized in our issue last week) on the use of tetra-ethyl lead in motor spirit. Moving that it was expedient for the Government immediately to set up a committee to advise on the public danger that might arise from such use, Lord Buckmaster remarked that last summer a very eminent medical man had told him that ethyl spirit was one of the most dangerous things which men could handle. This spirit, Lord Buckmaster proceeded, had been introduced by a powerful trade organization, and, so far as he knew, neither protection nor regulation from the Home Office or the Ministry of Health had been provided with regard to its use. Tetra-ethyl lead had been discovered in 1859, and in 1879 was classed as the most dangerous poison known. During the war it was considered as a poison gas, but was rejected because detonation destroyed some of its chemical molecules and some of its effects. Recently its use in motors was discovered, and was undoubted. By allowing greater compression than ordinary petrol vapours it enabled cars to take gradients more easily and also avoided "knocking." But this spirit contained as its essence tetra-ethyl lead, and that ingredient if put upon the hand or breathed in conveyed a grave risk of lead poisoning. As it was capable of being dissolved in oil and was very volatile there was no need for any abraded surface of the skin for this poison to take effect. The action was not necessarily instantaneous, but was a form of lead poisoning more deadly than that effected through the use of lead paint or of lead glazing, and illness came on without warning. This spirit originated in the United States, the Government of which appointed, some two years ago, a commission which reported that no positive evidence could be obtained of harmful effects, but which recommended further investigation. In America the use of ethyl-petrol was only allowed subject to rules and regulations issued by an authority equivalent to the Ministry of Health. Users in America were recommended not to spill the spirit on the floor of the garage, and advised to wash their hands before conveying food or tobacco to the mouth. Such recommendations were useless over here. We must act for ourselves. We had been warned. Lord Buckmaster quoted Sir William Pope, professor of chemistry at Cambridge, who said: "A garage hand who continually wets his skin with such a liquid, splashes it on his clothes, eats his food without scrupulous attention to cleanliness, or breathes an atmosphere tainted with the vapour, must thus be liable to contract lead poisoning." Professor Baker, Governor of the Imperial College of Science and Technology, wrote: "Lead tetra-ethyl passes rapidly through the skin, is absorbed by the blood, and causes very severe nervous trouble. If sufficient is absorbed, death occurs in a few weeks. . . I wrote, as president of the Chemical Society, to the Ministry of Health more than a month ago, calling their attention to the urgency of the matter. So far as I know, nothing has been done." Lord Buckmaster asked whether such a spirit was to be used unprotected and without any warning from the Ministry of Health. If Sir William Pope and Professor Baker were doubted there ought to be a committee of inquiry. Unless the Government acted nothing would be done, for trade organizations did not care how many people suffered from the exploitation of their goods.

Lord GREENWAY, supporting Lord Buckmaster's motion, spoke as one concerned in the oil industry, and said none of the petrol-producing companies desired to produce a spirit liable to criticism on the score of danger. It was essential to the public interest that a properly constituted board, including leading chemists and toxicologists, should be appointed to settle definitely whether tetra-ethyl spirit was toxic.

The MARQUIS OF SALISBURY denied that the Government was indolent in consideration of this matter, but admitted delay by the Ministry of Health in answering Professor Baker. The Government recognized the risk attaching to this commodity, and proposed to deal with it. Tetra-ethyl lead itself was highly dangerous. We manufactured dangerous things, such as vitriol and arsenic, but the greatest care ought to be taken. Tetra-ethyl lead was not manufactured in this country, but in America. A moment of special risk occurred when, having been imported into this country, it was blended with petrol spirit. That process was receiving the attention of the Home Office. No case of lead poisoning had arisen in England in consequence of the blending. The mixture

was one of tetra-ethyl lead in about 1,300 parts of petrol, and was undoubtedly a useful source of power. The Government had to consider how far it ought to interfere with an improvement in the source of power for petrol engines, especially for aeroplanes, where this spirit was particularly useful. The Public Health Department in America had appointed an investigating body of seven distinguished scientific men. This committee reported that no positive evidence could be obtained of harmful effects, and that drivers of cars using ethyl-petrol showed no definite signs of having absorbed lead after exposures approximating two years. These findings were very significant. The same committee reported that garage employees handling and repairing automobiles, and employees of automobile service stations, might show evidence of lead absorption, and that in garages and stations where ethyl gasoline was used the amount of apparent absorption was some what greater than in those without ethyl-gasoline, but the effect was slight in comparison with that shown by workers in other industries where there was definite danger from lead, and for the periods of exposure studied was not sufficient to produce lead poisoning. Lord Salisbury did not desire the House to accept these conclusions as conclusive, but suggested they should be cautions in condemning ethyl-petrol. The British Government was about to undertake research of a careful character, and was going to appoint forthwith an interdepartmental committee, probably comprising representatives of the Ministry of Health, the Home Office, and the Medical Research Council.

Lord BUCKMASTER said an interdepartmental committee was not the investigation he desired; departments did not have eminent scientific men on their staffs. The Medical Research Council had a certain number of doctors, but what was required were men such as eminent chemists. These would satisfy Lord Salisbury—who spoke lightly of a proportion of 1 in 1,300—that watered vapour from nickel would poison with 1 in 20,000. Professor Baker had written to him that after ethyl-petrol had burned in the cylinders of the engine the lead came into the exhaust as a fine lead oxide, and that in a crowded street, such as Piccadilly, the passer-by would be exposed to the same danger of lead poisoning as painters were before they were protected by Government action. The Americans had reported that workers in garages were slightly affected. Those people would become more and more affected till illness and death overtook them. He recognized that if he went to a division and beat the Government that would have no effect, so he proposed to withdraw his motion.

Lord SALISBURY said that if Lord Buckmaster thought that scientific men should be added to the interdepartmental committee he would make representations to that effect. Lord DANESFORTH pointed out that the committee would have power to call chemists and technologists as witnesses.

Lord Buckmaster's motion was withdrawn.

IN the House of Commons, on February 29th, Sir KINGSLEY WOOD said persons making or selling preparations of petrol containing tetra-ethyl lead should take or advise precautions to avoid danger from handling or use. There was at present no definite evidence of injurious results following the use of ethyl spirit, and pending inquiry the Government did not propose to issue warnings to garages or to local authorities. Answering Dr. Vernon Davies, Sir Kingsley said he did not know that in 1925 Switzerland prohibited by ordinance the use of tetra-ethyl lead.

Answering several questions in the House of Commons on March 1st, Mr. NEVILLE CHAMBERLAIN said the committee of inquiry which he proposed to set up would include the Government chemist and some men of science unconnected with any department, as well as representatives of the Home Office, Air Ministry, Medical Research Council, and Ministry of Health. The exact composition of the committee and its terms of reference had not been decided. He was not prepared to prohibit the use of ethyl-petrol until the committee had published its findings.

Mr. CHAMBERLAIN, on March 6th, in reply to Lieutenant Commander Kenworthy, said his attention had been called to the report arising out of tests carried out with petrol containing tetra-ethyl lead made by the Research Association of British Motor and Ethyl Lead made by the Research Association of British Motor and Ethyl Lead Manufacturers, founded under the auspices of the Department of Scientific and Industrial Research, in which the poisonous effects of the discharge of vapour from this fuel were described. Immediate steps were being taken to set up the committee of inquiry, which would be asked to report with the least possible delay. The Government did not propose to anticipate the findings of the committee by issuing a preliminary warning to the public concerning the use of this fuel.

The House of Commons took the opportunity to have a discussion on ethyl-petrol when Sir V. HENDERSON, on March 6th, moved the second reading of the Petroleum (Amendment) Bill. The bill is mainly designed to clear up certain difficulties in regard to the interpretation of Acts of Parliament, particularly that passed in 1871 dealing with petroleum, in view of the intention of the Government to bring in at a later date a bill to consolidate the whole of the law relating to petroleum.

Mr. HARRIS urged that the bill should contain regulations to ensure the safety of the public in dealing with petrol, including petrol containing tetra-ethyl lead.

Lieutenant Commander KENWORTHY expressed his dissatisfaction at the absence of any regulations in regard to the use of petrol containing tetra-ethyl lead. He said that the history of this substance in this country was extraordinary. In Switzerland the use of this highly dangerous poison was forbidden altogether. According to Sir William Pope, an acknowledged authority on this matter, the first use of this doped petrol in the United States of America led to five deaths and thirty or more cases of poison before suitable regulations were drawn up and applied. Although for months it had been advertised that this petrol had been put on the British market, not one regulation or warning of any kind had been issued by the Home Office, the Ministry of Health, or the Board of Trade.

He was glad to see that in the House of Lords attention had been drawn to this matter. That was the first opportunity he (Lieutenant Commander Kenworthy) had had of calling attention to the matter, except at question time, when Ministers could always ride off. He had been told that the Government were about to set up an interdepartmental committee to inquire into the matter, but it had not yet been summoned. It was certain that an interdepartmental committee meant delay, because the committee would take very great care over their evidence, findings, and report. Then the Government would delay further before they acted on the report of the committee, and in the meantime a great deal of mischief would have been done. The danger lay in two facts, one of which was that the spirit itself was poisonous. If any of the liquid got on to the skin it would be absorbed and bring on lead poisoning. Lead poisoning was slow in its effects, and came on gradually, but it was none the less deadly when it ran its course. This substance should never have been put on the market without orders being issued through local authorities and the police to garage proprietors and all who had to do with its sale, to warn the public against handling the liquid. The question of the effect on the general public in crowded streets was also of great importance. In traffic blocks the fumes from the ordinary petrol were most objectionable. At present the cities, and especially London, with their ever-increasing motor traffic, were suffering from a very foul atmosphere due to the exhaust fumes from motor cars. Scientific tests had been made by the Research Association of British Motor and Allied Manufacturers, which was founded under the auspices of the Department of Scientific and Industrial Research. A distinguished chemist, who carried out the research, stated categorically that the exhaust vapour from the use of this petrol was poisonous. He (Lieutenant Commander Kenworthy) contended that the Home Office had been wholly negligent in regard to this petrol being placed on the market.

No reply was made for the Government, and the bill was read a second time.

#### Reorganization of Offices (Scotland) Bill.

On March 5th the debate on the motion for the second reading of the Reorganization of Offices (Scotland) Bill, which had been adjourned from February 28th, was resumed. The bill provides for the transference of the powers and duties of certain Boards in Scotland, including the Prison Commissioners and the Board of Health, to a Department of Health for Scotland and a Prisons Department for Scotland.

Mr. SKEWTON said that nobody had ever suggested that the administration of health and other things for which the Board of Health was responsible was less efficient in Scotland than in England. Neither in the Parliament of 1922 nor in this Parliament had there been a single question raised as to the administrative efficiency of the Board. If the bill passed, he did not believe they would have first-class civil servants at the head of the Departments in Scotland. He opposed the bill because he was satisfied that the Government were taking an unjustified and unwise step, which would not be of any essential use at all.

Dr. DRUMMOND SMITHS opposed the bill. It was an attempt, he said, in the name of efficiency, and with a timid suggestion of economy, to approximate the Scottish system of government to the English system. The Board system was a more democratic form of administration than the one-man system. A great part of the functions of the Scottish Boards was to deal with local authorities. Members of those Boards were not simply secretaries and bureaucrats; they were people who, in many cases, had had outside technical and other training. Some of them had been actually members of local authorities, and they had to deal with local authorities. Such negotiations with local governing bodies were a very important element in the administration in Scotland, and was a function much more suitable for a Board than for a Civil Service head of a Department. He was specially interested in the Scottish Board of Health. The Secretary for Scotland, speaking in the previous debate, put a great deal of emphasis on the report of the Royal Commission, which, he said, condemned the Board system in Scotland. But the Royal Commission was dealing with an entirely different kind of Board, and was referring almost entirely to the Local Government Board. The Board of Health met at least once a week, and sometimes oftener, and had minutes kept of its proceedings. It was under the chairmanship of the Under Secretary for Scotland, and was a very different Board from the old Local Government Board. On the present Board there was the head of the National Health Insurance of Scotland, a representative of the legal department, and of the pensions and medical departments. The position of head of the medical department was likely to be vacant in a very few weeks. Who was going to be appointed to succeed the very distinguished present head of that department? There were men junior to him in that department who were suitable to be appointed, and were familiar with Scottish local government. Was one of those to be appointed, or were they to have appointed to that important position in Scotland, requiring a very intimate knowledge of Scottish local authorities, an official from the English Ministry of Health? They must wait and see; but he was very suspicious that some change of that kind was likely to take place. The heads of the Scottish medical department and the junior medical officers had been in the past men who had been medical officers of health in important towns in Scotland. The House, he thought, would agree that a man who had had experience of the work of a medical officer of health in some of the large towns of Scotland was the proper type of man to be at the head of their national medical department. The bill took away some of the last traces of Scottish individuality and sentiment from the administration of their country. It was really a triumph for bureaucracy at the expense of their national sentiment.

Mr. JAMES STEWART, while opposing the bill, said that the proposals of the Secretary of State for having all the departments under one head would produce good results. If they took the health administration they would find that in Edinburgh it was divided into three buildings in three different parts of the city. If the Government would introduce any proposals for providing the buildings which were clamantly necessary, so that they could have the Scottish departments under one roof, there would be whole-hearted support from the Labour party for the bill. It seemed to be suggested that there was difficulty in getting advice from the heads of the departments. His experience in office was a very brief one, but it taught him that it was easy to get into touch with the head of any department. Suppose that it was a medical problem relating to the health administration in any part of the country, and he wanted advice. He applied to the head of the department for his experience and advice. That advice was freely tendered and as freely accepted, and was very generally acted upon, because one knew that there were ability and experience behind it. There was complete independence on the part of the head of the department and on the part of the person who had to supply the Minister with advice. Then again, one had the benefit, every Friday morning, of a Board of Health meeting at which the heads of the various departments were present. Either the Secretary or Under Secretary for Scotland took the chair, and deliberated on the problems for discussion. They had the benefit of all the experience of the members of the Board, and, finally, the Minister had to assume responsibility. It was he who came to a conclusion even if, as happened sometimes, the whole of the Board was against the Minister. If his experience and that of the Secretary for Scotland had been similar then the changes proposed in the bill could not be beneficial. It was beneficial also for local authorities to meet the Board of Health to discuss the health administration of the local bodies. For that very strong reason they ought not to depart from the Board of Health and create new departments. There had been for some time a movement for bringing about unity among local authorities. Economy and efficiency could be developed in a way that was not possible under the present system.

Mr. D. GRAHAM said that they had no complaints against the various boards. He had met the Board of Health and had nothing but pleasant recollections of the meeting. He regarded every member of the Board as well qualified; they were always courteous and willing to hear one, and they always produced arguments for any decision they gave.

The Lord Advocate, replying to the debate, said that at the present there was no first-class Civil Service position open to a Scotsman in Scotland, but the bill would make that possible. In reply to Dr. Shiels, there could be no doubt whatever that the men who were appointed would have the same capacity for administration as the existing individual members of the Board in their particular department. What was wanted was administrative knowledge, the power of taking a concentrated opinion, as an administrator, of all the expert knowledge available. That was the vital thing, and was one of the reasons why he said, quite frankly, that the Boards were not as efficient as a Department would be. Certainly, at the beginning, and he hoped in succession, the existing members of the Board of Health would remain in office. In form their appointment would be different, but they would be there, and their expert knowledge would be continuously available. There would be no change in that aspect of the matter, and the advisory councils would carry on just the same as at present.

The second reading was carried by 161 votes to 66, and the bill was committed to a standing committee.

#### Small-pox.

Mr. NEVILLE CHAMBERLAIN furnishes the following provisional figures for deaths in England and Wales during 1927 in respect of which small-pox appears on the medical certificates as the cause, or one of the causes, of death: Quarter ended March, 1927, 19; ended June 30th, 17; ended September 30th, 7; ended December 31st, 6.

On March 5th Sir KINGSLEY WOOD informed Mr. C. Edwards that the Minister of Health had received a letter from the Bedwellty Council asking that the law should be amended so as to provide that in the case of persons who had been in contact with, or were suffering from, small-pox or other infectious disease in casual wards of Poor Law institutions, the medical officer of health should be empowered to have them detained and isolated for such period as he might deem necessary. Sir Kingsley added that there was power under the present law to secure the removal to hospital of any person who was suffering from a dangerous infectious disease and was without proper lodging or accommodation, but, as at present advised, the Minister of Health did not think it necessary to introduce legislation conferring similar powers in regard to persons who had been in contact with cases of such diseases, though not themselves suffering.

#### Pensions and Service Hospitals.

Answering Dr. Drummond Shiels, on March 1st, Major TAYLOR said arrangements had been made, as already announced, to close Craigleith Hospital, and the patients remaining in that institution, who occupied less than one-fifth of the available accommodation, would be removed to Edinbush, which had been placed at the disposal of the Government by the Scottish Red Cross, and was being fully equipped as a modern surgical and medical hospital. The closure of Bellahouston Hospital was not at present in contemplation. He was anxious to extend the Ministry's tenure of this hospital, and was in communication with the Glasgow Corporation with that object. He hoped that a satisfactory

At the meeting of the West Kent Medico-Chirurgical Society, to be held at the Miller General Hospital, Greenwich, S.E., to-day (Friday, March 9th), at 8.45 p.m., Dr. Maud M. Chaddburn will read a paper on the radium treatment of cancer of the cervix uteri.

WE regret to learn that Dr. W. J. Howarth has been compelled by ill health to resign the appointment of medical officer of health for the City of London. Dr. W. M. Willoughby, medical officer for the Port of London, is acting temporarily in Dr. Howarth's absence until a successor is appointed.

THE annual meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, W.1, on Thursday, March 22nd, at 5.30 p.m., when the annual report and financial statement for the year ending December 31st, 1927, will be presented, and the officers and committee for the current year elected.

THE Physical Treatment Centre of the Kensington Division of the British Red Cross Society at The Limes, Holland Park Gardens, W.14, will be open for inspection by medical practitioners on Thursday, March 22nd, at 8.30 p.m. Dr. James Meenell will give a short lecture on foot trouble and foot gear.

A SESSIONAL meeting of the Royal Sanitary Institute will be held in the Council Chamber of the Town Hall, Scarborough, at 5 p.m. on Friday, March 16th, when a discussion on the Scarborough water supply and new scheme will be opened by Mr. Herbert Lapworth, D.Sc. The chair will be taken by Professor A. Bostock Hill.

THE next evening meeting of the Pharmaceutical Society of Great Britain will be held in the lecture theatre of the Society's House, 17, Bloomsbury Square, London, W.C.1, on Tuesday, March 13th, when an address will be given by Dr. H. H. Dale, secretary of the Royal Society, and head of the Department of Biochemistry and Pharmacology, National Institute for Medical Research, upon some reactions of pharmacology on pharmacy. The president will take the chair at 8 p.m.

A SPECIAL discussion on the pulpless tooth will be held at a combined meeting of the Sections of Odontology, Pathology, and Electro-therapeutics of the Royal Society of Medicine at the Society's House, 1, Wimpole Street, W.1, on Monday, March 26th, at 8 p.m. Mr. Frank Coleman will open for the Section of Odontology and Dr. H. M. Worth for the Section of Electro-therapeutics.

THE meeting of the Society of Medical Officers of Health for a discussion on the control of small-pox fixed for March 16th is postponed until a date to be announced after publication of the report of the Departmental Committee on Vaccination.

THE Fellowship of Medicine announces that Dr. J. L. Birley will lecture on the high-grade defective in relation to general practice on March 12th, at 5 p.m., in the lecture room of the Medical Society, 11, Chandos Street, Cavendish Square. On the following day, Dr. R. T. Parsons-Smith will give a special clinical demonstration at the National Hospital for Diseases of the Heart at 11 a.m.; and on March 15th Mr. R. H. Jocelyn Swan will give a special clinical demonstration at the Cancer Hospital at 2 p.m., replacing the one originally announced for March 16th. The lecture and demonstration are free to medical practitioners. Three special courses begin on March 19th. The first, at the Brompton Hospital, lasts a week and occupies mornings and afternoons. The two other courses continue for two weeks; one, at the Royal National Orthopaedic Hospital, occupies the whole day with operations, lecture-demonstrations, and work in the out-patients' department; the second, at the Hampstead Hospital, continues from 4.30 p.m. to 6 p.m., and comprises a lecture and a demonstration, each day in medicine, or in surgery, or in one of the allied departments. There will be no special courses from March 31st until April 16th. Comprehensive tickets are, however, issued for any period from one week to one year.

Information about the various courses at various hospitals, and specimen copies of the *Post-graduate Medical Journal* may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

Dr. O. REES, chairman of the West Dorset Division of the British Medical Association, and a member of the executive of the Panel Committee and also a member of the Dorset Insurance Committee, has been elected a member of the Dorset County Council. The total votes polled for him exceeded the combined totals of the other three candidates.

SIR FRANCIS CHAMPNEYS, Bt., M.D., president of the General Lying-in Hospital, London, S.E., presided at the annual general meeting of the governors on February 29th. It was recalled that the institution was founded by Dr. John Leake in 1765 for maternity cases. The out-patient district includes Westminster, Lambeth, Southwark, Camberwell, and Battersea. A feature of the hospital's work is the training of midwives.

IT is now announced that the fifth international congress on thalasso-therapeutics will be held at Bucarest and Constantza from May 21st to 29th.

THE annual congress known as Journées médicales de Bruxelles will be held at Brussels from April 21st to 25th, when the following papers among others will be read: Ileocaecal excision in diseases of the ascending colon, by Mario Donati of Paris; arterial oncephalography, by Egas Moniz of Lisbon; cardiac syncope and adronaline, by Emile Bardier of Toulouse; preventive inoculations, by C. Zoeller of Paris; cholangogue function of the liver, by Noel Fiessinger of Paris; carbohydrate metabolism, by Cesaro Serono of Rome; heliotherapy of surgical tuberculosis, by A. Rollier of Leysin; rheumatism in the menopause, by M. P. Weil of Lyons; neurology of the abdominal wall, by G. Södenbergh of Gothenburg; and plastic surgery of the face, by Sanvencro-Roselli of Genoa.

THE forty-first congress of the French Society of Ophthalmology will be held at the Faculty of Medicine of Paris from May 14th to 16th, when a paper will be read by Dr. Mawas on the biomicroscopy of the iris in health and disease. Further information can be obtained from the general secretary, Dr. René Onfray, 6, Avenue de la Motte-Picquet, Paris VII.

THE Standing Committee appointed by the Board of Trade to consider whether imported surgical, medical, dental, and veterinary instruments, dental supplies and dental furniture, should bear an indication of origin, announce that their inquiry has been postponed, and will be now hold on March 19th and 20th.

DURING the fourth year of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation fifty-five applications for grants were received by the trustees, twenty-one of which came from the United States and thirty-four from eleven different countries in Europe and Asia. Twenty-four grants were made during 1927, including one to Dr. J. B. Dawson of Edinburgh for investigating the pathology of the breast. Applications for grants for the coming year should be sent to Dr. J. C. Aub, Massachusetts General Hospital, Boston 14, before May 15th.

THE February issue of the *Deutsche Zeitschrift für Chirurgie* is dedicated to Professor Alexander Fraenkel, director of the surgical division of the General Polyclinic of Vienna, on the occasion of his 70th birthday.

MESSRS. W. HEFFER AND SONS, Ltd., announce for early publication *Practical Serology*, by Professor Luigi Vignano of Milan, translated from the latest Italian edition by Miss E. M. Heffer, and edited by Dr. C. G. L. Wolf.

WILLIAM HEINEMANN (Medical Books) Ltd. announce for early publication *Tonsils and Adenoids and Their Diseases: Including the Part They Play in Systemic Disease*, by Dr. Irwin Moore.

RESOLUTIONS emphasizing the importance, in combating malaria, of co-ordination between the public health authorities and the promoters of engineering works were passed by the Malaria Section of the Far Eastern Association of Tropical Medicine at the seventh congress, Calcutta, in December last, on the proposal of Sir Malcolm Watson, M.D., seconded by Lieut.-Colonel S. R. Christophers, I.M.S., director of Central Research Institute, Kasauli. Reference was made to the fact that many cases had occurred in which a great increase in the incidence of malaria had been caused by facilities given by engineering works, and it was resolved that such works likely to affect malaria should be submitted to the authorities before being sanctioned. The congress concluded that there was no single method of malaria control applicable to all conditions and all countries, but, whatever other measures might be adopted, control of the mosquito breeding places should be employed where there were large aggregations of people.

THE following German medical congresses will be held next month: Röntgen Society, April 11th to 14th, at Berlin; Society for Internal Medicine, April 16th to 19th, at Wiesbaden; Pathological Society, April 19th to 21st, at Wiesbaden; Society for Psychiatry, April 24th and 25th, at Kissingen.

THE following appointments have recently been made in foreign faculties of medicine: Dr. Erich Lexer of Freiburg, professor of surgery at Munich; Professor G. A. Wagner of Prague, professor of gynaecology at Berlin; Professor Marx of Münster, professor of otology at Würzburg; and Professor W. Kerl of Innsbruck, director of the dermatological clinic at Vienna in succession to Professor Finger.

PROFESSOR ARDIN-DELTHIL has been nominated dean of the medical faculty of Algiers.

PROFESSORS NICOLAS and PIERRE DUVAL of Paris have been elected foreign corresponding members of the Royal Academy of Medicine of Belgium.

A COMMITTEE has been formed at Tunis to commemorate the twenty-fifth anniversary of Dr. C. Nicolle's appointment as director of the Institut Pasteur of that city. Further information can be obtained from Dr. F. Gérard, 100, Rue de Sébile, Tunis.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 3861, 3862, 3863, and 3864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Atiology Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

### QUERIES AND ANSWERS.

#### ACUTE GOUT.

"HON. SEC." asks for information about any modern treatment likely to be useful in a case of acute gout, in which all the old remedies have been tried and failed.

#### WANTED—A HOME.

"MEMBER OF THIRTY YEARS' STANDING" would be glad to hear of a home in pleasant surroundings, where an old lady could be placed voluntarily for moderate payment, in some such place as Bournemouth.

#### CRAMP AFTER SCIATICA.

"K." asks for suggestions for the cure or mitigation of cramp in the leg following an attack of sciatica. The trouble is mainly at night, and causes loss of sleep. It appears to be increased by any exercise.

#### DURATION OF A POSITIVE VIDAL REACTION AFTER INOCULATION.

DR. M. AVENT (Basingstoke) asks how long the effect of inoculation with T.A.B. remains as regards agglutination powers of the serum of the person inoculated. One or two bacteriologists hedged, but implied only two or three years. He has recently seen a case which was diagnosed as being typhoid fever largely on the strength of a Vidal reaction, which the bacteriologist reported as "strongly positive to *B. typhosus* and negative to *B. paratyphosus* A and B." The man had been inoculated with T.A.B. over ten years previously. The diagnosis was eventually settled as splenic anaemia.

#### PRIMULA RASH.

DR. FRANCIS G. BENNETT (Bournemouth) writes: For some time I have been attending a patient for a rash on the hands due to handling the above-named plant. Applications of various kinds have answered for a time, but the rash still continues to appear at intervals. This obtained also with respect to the ultra-violet rays, which were given a good trial. I should be grateful for any suggestions as to treatment, as both the reappearance of the rash and the irritation which accompanies it are becoming distressful to the patient.

"\* \* We have referred this inquiry to Dr. H. Haldin-Davis, who writes: The first point in the treatment of this case is to ensure that the patient never, on any account, handles a *primula* at all. Unless this precaution has been taken (and Dr. Bennett does not make it quite clear that it has), no treatment is likely to be successful. If, however, the rash remains obstinate, even although care has been taken that there should be no renewal of the harmful contact, one must suppose that the patient is so sensitive that the original dermatitis has developed into a true eczema—a contingency by no means improbable; the tendency of eczema to relapse is notorious. It is difficult to give explicit directions without seeing the patient, but the keynote of the treatment should be protection, as complete as possible, from external irritants of every kind, however slight.

#### INCOME TAX.

##### Schedule B: Purchase of Practice.

"L. C." asks whether he is correctly assessed in respect of a meadow under both Schedule A and Schedule B, and also as to the position arising out of the purchase of the remaining

half share in the practice from his former partner as from December 31st, 1927. During the quarter ending April 5th, 1928, he will be paying an assistant at the rate of £400 per annum inclusive.

"\* \* The tax is payable under both Schedule A and Schedule B. Our correspondent is not entitled to deduct the expense of the employment of the assistant from the share of the 1927-28 assessment relating to the last quarter. The only relief open to him is to claim under Rule 11 to have the proportion of the assessment applicable to the final quarter reduced to the amount of the profits of the practice for that period. In computing those profits he would, of course, deduct as an expense of the practice the £100 payable to the assistant for that quarter.

#### Motor Car Obsolescence.

"C. A. R. M." bought a car for £295 in September, 1925, which he sold in September, 1927, for £150, buying another car for £255. Depreciation has been allowed, but the claim for obsolescence (presumably on £145 less £40 depreciation—that is, £105) has been refused on the ground that the 1925 car was not "obsolete."

"\* \* Apparently the inspector of taxes is relying on the case of the South Metropolitan Gas Company v. Dadd, which was decided by Mr. Justice Rowlatt last November. The decision went in favour of the Crown on the ground that the question was one of fact, and that the Court therefore could not interfere. But the judge went out of his way to say that this case was not to be taken as deciding that in order to be obsolete a thing must be "worn out," and suggested that in that particular case the Commissioners against whose decision the appeal was made had in mind the probability that the appellant company "wanted something rather better . . . because it would suit their purpose better." The case quoted dealt with the replacement of a seven-year-old ship. It is clear that the life of a medical practitioner's car is normally so much shorter than that of a ship that there is prima facie less ground for attacking a claim for a two-year-old car than for a seven-year-old ship. Further, there can be no suggestion that our correspondent was buying the new car for any other reason than that the old one had become unsuitable by age and use for the purpose for which it was required. If the inspector of taxes remains obdurate on the merits of the claim—and even if the legal merits are arguable the equitable merits are not open to dispute—we suggest that a full statement of the facts be sent to the Secretary, Inland Revenue, Somerset House, W.C.2, with a request for an official ruling. In that event we should be glad to see a copy of the reply.

### LETTERS, NOTES, ETC.

#### A MEDICAL MAN-OF-ALL-WORK.

DR. WILFR (Bridgnorth) sends us the following, copied from the *Bath Chronicle*, which may be found in the *Hereford Journal* for March 27th, 1777:

"Wanted for a family who have had health—a sober steady person in the capacity of doctor, surgeon, apothecary and manmidwife. He must occasionally act in the cap. of butler, dress hair and wigs, must occasionally read prayers occasionally and a sermon every Sunday evening. A good salary will be given. N.B.—He will have liberty to turn a penny in any branch of his profession when not wanted in the family."

Perhaps (our correspondent adds) the omission of the usual qualification before "penny" is indicative of delicate politeness.

#### A BEGGING LETTER, PEST.

IN our issue of August 13th last we warned our readers that a begging letter expert was operating from Cardiff—a woman who appealed for loans to help her father, described as a former medical student. This woman is still sending out her appeals on much the same lines, and we hear from the Chief Constable of Cardiff that she has already been by three pretences. It seems to be chosen as a specially favourable prey, and we on guard.

#### THE WHITE LINE.

THE police authorities have determined to prosecute to keep to the white lines on cuts in cases where every motorist when approaching roads. It therefore behooves every motorist when approaching corners and round junctions to look out for the white lines and keep well within them.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 46, 47, 50, 51, and 52 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 48 and 49. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 83.

# An Address ON GENITAL DISPLACEMENTS.\*

BY  
VICTOR BONNEY, M.S., B.Sc., F.R.C.S.,  
ASSISTANT GYNAECOLOGICAL SURGEON TO MIDDLESEX HOSPITAL; SURGEON  
TO CHelsea HOSPITAL FOR WOMEN.

## THE PELVIC FLOOR AND THE PELVIC SHELF.

SINCE the cure of all deformities and displacements must be founded on a correct understanding of the anatomy of the parts concerned, I will begin by reminding you of the structures that keep the female genital canal in position. They may be divided into three groups as follows: (1) The broad ligaments with all the structures contained within them that are attached to the body of the uterus. (2) The cardinal ligaments and pubo-cervical musculo-fascia, which collectively I call the "pelvic shelf." (3) The levatores ani and other muscles that close the outlet of the pelvis, together with the fascial layers in relation to them; the whole being named the pelvic floor.

The first of these three groups is the least important, for the broad ligaments have no great fixing power on the uterus, but merely, so to speak, steady it like the guy-ropes steady a tent pole, though its main support is the ground into which it is driven.

The second group is of far greater importance, for the cardinal ligaments not only keep the vagina in its normal position, but also hold the cervix. They spring from the sides of the vagina, from its vault down to the upper surface of the levatores ani, and it is this arrangement that makes the lateral walls so fixed. They spread out fan-shaped, to become attached to the lateral pelvic wall on each side along the so-called "white line," like the wings of a butterfly whose body is formed by the vagina and the musculo-fascias which ensheath it, the whole forming a shelf of considerable rigidity, projecting out into the pelvic cavity. On the upper and anterior surface of this shelf the bladder and ureters lie, and its posterior surface is separated in the mid-line from the rectum by a thin layer of loose cellular tissue, whilst on the sides it is separated from the lateral rectal ligaments and upper surface of the levatores ani by wads of fibro-fatty tissue. The reality of this structure which I have ventured to call the "pelvic shelf" can only be appreciated by deep dissection such as has to be undertaken in Wertheim's operation. It is of great importance, for on it the position and stability of the cervix and vagina and bladder depend. The plane in which it normally lies is roughly parallel to, though considerably below, that of the pelvic brim.

The pelvic floor, on the other hand, lies in a plane which, in the standing posture, is practically horizontal, and therefore at an angle of about 45 degrees to that of the pelvic shelf. Its function is to support and fix the lower ends of the rectum and vagina respectively, and that part which supports and fixes the vagina is not only the weaker portion, but it is much more liable to be injured in the process of childbirth. Weakness leading to yielding, either of the pelvic shelf or pelvic floor, or of both together, is the fundamental cause of uterine and vaginal displacement, and therefore, in determining the measures to be employed for their cure, it behooves us to find out in each individual case which of the two structures I have described is primarily at fault.

## THE MECHANISM OF RETROVERSION.

Retroversion may come about in one of three ways. In the first the fault lies solely with the broad ligaments, which, being weak, allow the body of the uterus to be

unduly mobile. In the second there is weakness of those upper fibres of the cardinal ligaments which fix the cervix at its juncture with the vagina. The result is that the uterus is loosely set into the vagina, and in recumbency it tends to drop back towards the hollow of the sacrum. This tendency is no doubt resisted by the broad ligaments if they themselves are normal; but just as the guy-ropes would not long hold a tent pole once it had come out of the ground, so soon or later the uterus falls back. In this class of case the uterus is not merely retroverted, but is lower in the pelvis than normal. The third way in which retroversion of the uterus can come about is by the whole pelvic shelf retroverting. This displacement of the uterus is sometimes called "retroposition," but the term seems to have been coined without understanding the processes at work, and without noticing that in these cases the vagina is retroverted as well. Cases of this deformity are constantly mistaken for cystocele because, on looking through the vaginal entrance, the anterior vaginal wall is seen immediately behind it, and much lower than normal. On straining it may even partially protrude, but this is not because it is bulging abnormally, but because the axis of the canal is tilted back so far that the anterior wall only requires a normal degree of bulging to reach the orifice.

## THE MECHANISM OF PROLAPSE.

Prolapse in its essence is the vagina beginning to turn, or actually completely turning inside out. The uterus not only plays no active part in this performance, but actually passively resists it. In other words, the vagina can turn inside out more easily if the uterus is not there, and this is the reason why the greater degrees of prolapse are mostly seen after the climacteric, when the uterus has atrophied. For a hollow viscus to turn inside out an initial bulge inwards of some area of its wall is necessary, and in the case of the vagina this bulge practically always starts either on its anterior or its posterior wall, or its vault, for the lateral walls, by reason of the cardinal ligaments attached to them, are too rigid to bulge. The exact position of this initial bulge or "dropping" depends on which part of the supporting apparatus is yielding under the intra-abdominal pressure.

In normal circumstances the axis of direction of the intra-abdominal pressure during straining is downwards and backwards behind the uterus into Douglas's pouch, into which coils of small intestine may be forced, just as they are forced into a hernia sac when the patient coughs. This happening not only compresses the rectum against the sacrum and forms an important factor in the act of defaecation, but the pressure being applied behind the uterus and the pelvic shelf, the uterus, the vagina, and the whole shelf tend to be pushed forwards and slightly upwards, so that so long as the posterior vaginal wall is equal to the strain, no abnormal bulge into the vagina occurs. When, however, the uterus is retroverted, and more especially when the vagina is retroverted as well, the axis of direction of the intra-abdominal pressure is forwards of the uterus, and the pressure is chiefly exercised in crowding down coils of intestine on to the back wall of the bladder, and on to the pubo-cervical musculo-fascia and vaginal wall which lie immediately beneath it. The result is a tendency for the anterior vaginal wall to bulge abnormally, and this is rendered the more easy if the pelvic floor has been so weakened in its anterior part that the vagina gapes. The point at which the primary bulge occurs differs in different cases. Thus it may be situated at its upper part only, the anterior vaginal vault—that is, that portion of the wall which is above the trigone of the bladder—in which case the protrusion contains no bladder; or it may be situated at that portion against which the trigone lies, in which case a true cystocele is formed; or it may be situated at its lower end, in which case the

\* Introducing a discussion of the subject at the New Zealand Medical Association Meeting at Hamilton, N.Z., February, 1928.

urethra is displaced, with the result that the patient wets herself when she strains.

Prolapse of the anterior vaginal wall is not invariably accompanied by retroversion of the pelvic shelf, or even by simple retroversion of the uterus, but it is so in the majority of cases. Moreover, a something additional to retroversion is required—namely, that stretching and weakening of the pelvic shelf, either in whole or in part, which labour alone can bring about. Thus prolapse of the anterior vaginal wall is very rare in nulliparae.

Prolapse of the posterior vaginal wall, on the other hand, is not primarily dependent on the yielding of the pelvic shelf, but is chiefly brought about by post-parturient weakness of that part of the pelvic floor which supports its lower end. As a result, every time the woman strains this lower attachment is pulled down by the bulging floor, and the posterior vaginal wall becomes elongated so that it droops forwards into the vaginal lumen. At this stage the protrusion is not accompanied by a protrusion of the rectum, the vagina merely slipping down on the front of the rectum. Presently, however, the rectum, deprived of its support in front, commences to slip down the face of the sacrum and buckle forwards, so that the protrusion becomes a true rectocele. This buckling forwards of the rectum depends on the posterior part of the pelvic floor maintaining its stability, for if it bulged too, a rectal prolapse, and not a rectocele, would result. The protrusion is rendered the more easy because of the gaping vaginal orifice which the absence of the perineal body and laxity of the levatores have brought about.

There is a rare form of prolapse of the posterior vaginal wall which does not primarily depend on weakness of the pelvic floor, but is due to a bulge inwards of that upper inch which is in relation to Douglas's pouch. This form of prolapse is a true hernia of the pouch. Speaking generally, prolapse of the posterior vaginal wall, when occurring by itself, is commoner with the uterus in anteversion; and this is what would be expected, for then the axis of direction of the intra-abdominal pressure lies posterior to the uterus, and exercises an effect chiefly on the posterior wall and rectum.

Though prolapse, to begin with, is initiated by a bulge inwards of some particular area of the vaginal wall or vault, it is comparatively rare for the clinician to see the case until several areas of the whole of one or both walls are bulging, for weakness of one part of the supporting apparatus is soon followed by weakness of other parts, owing to the increased strain put on them by the failure of the primary defaulter, until in the end, all of them having failed, the vagina turns inside out.

#### OPERATIVE TREATMENT.

In these days, when the operative treatment of displacement has reached so high a pitch of satisfactoriness and reliability, no other treatment needs to be considered in the vast majority of cases. The exceptions to the rule are: First, cases of retroversion or prolapse discovered so soon after labour that further involution of the stretched supporting apparatus may be hoped for, if the strain on the parts be temporarily removed or lessened by the wearing of a pessary; a pessary worn this way, as a splint, pending nature's reparative processes, is without objection, but it is objectionable when employed as a permanent orthopaedic apparatus. Secondly, there are those cases of prolapse in aged persons whose physical condition is too feeble for an operation. Age by itself is no contraindication; I have operated several times on women over 80 years of age, with prolapse quite incapacitating them, when pessaries could not be worn.

From a consideration of the mechanism and varieties of genital displacement that I have put before you, one fact is immediately apparent—namely, that no one operation will suffice to cure the many varieties of deformity which come under this head. As in orthopaedic surgery in general, so in that part of it which is concerned with displacements of the genital canal—in particular, the operations may be divided into two categories: those which have as their object the repair of the faulty supporting

apparatus, and those which discard it in favour of making a substitute. Thus perineorrhaphy with suture of the levatores and the fascia superficialis to them is a repair operation, because it directly mends the parts at fault; whilst ventrofixation is a substitution operation, because it discards the natural supports of the vaginal vault and replaces them with a new ligament made out of the uterus. Both repair operations and substitution operations are legitimate, and both have their own sphere of propriety and usefulness, and it is the task of the surgeon to decide which amongst them is the most applicable to the deformity present in the individual case. In the abstract repair is superior to substitution, but in practice we often have to deal, not with normal tissue, but with tissues that have permanently lost much of their original strength and resiliency, and in such cases repair may be impossible altogether, and compel absolute substitution—or, being possible, be insufficient without a degree of substitution.

#### Retroversion.

When operating for retroversion of the uterus we have to distinguish between the three classes of case: in the first of these the fault lies solely with the lax broad ligaments; in the second it centres round the point of insertion of the uterus into the vaginal vault, the extreme upper fibres of the cardinal ligaments being deficient; whilst in the third the defect is a weakness of the whole shelf. The first two varieties are often met with in young unmarried girls, and bear no necessary relation to child-bearing. A congenital defect is often alleged to be the cause in these nulliparous cases, but the term "growth defect" is better, for probably the fibres which should hold the cervix in its normal position fail to keep pace with the enlargement of the uterus that occurs after puberty. The third variety is, I think, always the result of child-bearing, and in these cases the vagina is retroverted as well as the uterus. For the first variety the sling operation is eminently suitable, but for the second it is not ideal, because it does not raise the uterus sufficiently, and the operation of shortening the round ligaments by retroperitoneal plication is to be preferred. In the third variety both of these operations are insufficient because they do not lift the retroverted pelvic shelf, so that though the uterus is brought forwards the entire deformity is not corrected, and later on the patient is liable to return on account of retroversion or prolapse of the anterior vaginal wall. For such cases an operation which pulls up the uterus much higher and much more strongly is needed. Ventrofixation effects this object, and to a lesser extent so does the modification of round ligament shortening that I have employed for some years, which in effect secures strong ventrosuspension from each cornu. Which of the two should be chosen in any particular case has to be decided by consideration of the exact degree of the deformity, the character of the patient's physique in general, and the texture of the pelvic tissues in particular.

#### Prolapse.

In the treatment of prolapse a number of operations are at our service, all of which have their spheres of applicability and inapplicability. In deciding which of them is suitable to the individual case, the surgeon has to make up his mind: (a) which part of the vagina prolapses, and therefore which part of the supporting apparatus is at fault; (b) whether there is redundancy of the tissues or not; (c) the position of the uterus and pelvic shelf.

In regard to the site of the bulge in vault prolapse and its underlying cause it is the upper fibres of the cardinal ligaments that are relaxed, and these, to an extent, can be tightened from the vagina by exposing them through the lateral fornices after having amputated the vaginal cervix and suturing them together, either in front or behind the cervical stump. The alternative is to discard them altogether and make a new vault ligament out of the uterus by ventrofixing it.

In cystocele it is the pubo-cervical musculo-fascia which is lax and needs repairing, and this can be accomplished

by anterior colporrhaphy, providing that the musculo-fascia is tautened by suture as well as the vaginal wall. When vault prolapse and cystocele are both present Pothorgill's operation is suitable, for it tautens both the pubo-cervical fascia and the upper fibres of the cardinal ligaments. An alternative is to combine anterior colporrhaphy with ventrofixation. Which of the two is the better depends on the individual case, but both, when properly applied, give happy results. Another alternative is the interposition operation, which effects some tautening of the fibres of the cardinal ligaments and markedly strengthens the middle section of the pelvic shelf. When the whole shelf has retroverted ventrofixation is indicated, for it cannot be lifted except from above. Laxity of the pelvic floor is perfectly corrected by perineorrhaphy properly performed—that is to say, with suture both of the levatores and the fascia superficial to them. I emphasize this because the latter are sometimes missed.

For rectocele posterior colpoperineorrhaphy meets the case, but in that rare form of prolapse which is a true hernia of Douglas's pouch colporrhaphy by itself is rarely efficient, because the upper part of the posterior vaginal wall is defective, so that the vaginal operation had better be supplemented by obliterating Douglas's pouch from above by suturing the rectum to the back of the uterus.

The question of redundancy of tissue is important because, if it exists, the reparative operation must include the reducing of it by amputation of the cervix or excising large areas of vaginal wall. On the other hand, it is quite common to meet with cases of prolapse in elderly women in which there is not only no redundancy of the cervix and vagina, but actually a diminution of tissue, and in such, if the surgeon unthinkingly excises more, he will have difficulty in bringing together the cut edges of the frail vaginal wall—a most disconcerting experience. Since the ease with which the vagina can turn inside out depends in part on the relation between the thickness of its wall and the size of its lumen, any variety of prolapse can be prevented by sufficiently narrowing the canal. This is the effect of Le Fort's operation, which leaves the patient with a double vagina, each half of which is so narrow that in-falling of its wall is impossible. Great narrowing of the canal is, however, only allowable when the patient no longer has relations with her husband on account of age.

The position of the uterus is important, because if it is retroverted the reparative operation must include the rectification of that part of the displacement, for if it be left backwards the abnormality of the axis of direction of the intra-abdominal pressure remains as before, and menaces a further displacement. The size, or rather length, of the uterus should always be measured with a sound if one wishes to escape the error of opening the abdomen to ventrofix a uterus which is too small to be brought up to the abdominal wall—a state of affairs quite common in aged fat women. Finally, the position of the pelvic shelf must be ascertained by noting the direction of the axis of the vagina, and if it is retroverted steps must be taken to bring it up.

#### Conclusion.

The exact methods by which these various aims can be achieved I do not intend to discuss, because the object of this introductory paper is to summarize the basic facts of genital displacement, a full appreciation of which is a necessity if the operations for its relief are to constitute a science as well as an art. A surgeon who proclaims that the operation he employs for prolapse is Jones's or Smith's or Robinson's also proclaims himself as belonging to that considerable section of mankind who prefer to get someone else to think for them. Fancy a tailor who advertised that he corrected the bad fit of a pair of trousers by Jones's method! Gentlemen, in the matter in hand we are all tailors, and our aim should be not to carry out any particular preconceived set operation, but, in the words of Gilbert's immortal Lord High Executioner, "to make the punishment fit the crime" by employing just those dissections, excisions, readjustments, and suturings which will, if possible, leave the parts concerned "as good as new."

## A Clinical Lecture ON GASTRO-JEJUNAL ULCER.\*

BY  
R. P. ROWLANDS, M.S., F.R.C.S.,  
SURGEON TO OUR'S HOSPITAL.

I AGREE with Balfour<sup>1</sup> that "recurrence of ulceration may follow any operation for peptic ulcer, including partial gastrectomy." Gastro-jejunal ulcer, of which two grave examples are recorded below, is the commonest secondary ulcer and the most serious complication of gastro-jejunosomy. It may appear at any time from a few days to twenty or more years after the primary operation. It is generally taught that a new ulcer appears sooner or later at, or near, the stoma after about 2 per cent. of gastro-jejunosomies performed for non-malignant disease. Balfour found the percentage to be 1.6 after 8,600 gastro-enterostomies at the Mayo Clinic; but many patients suffer from this complication who do not seek another operation, but do everything possible to avoid one, and I have reasons for thinking that it is far commoner than is generally believed. After seeing and treating many of these difficult cases, I have come to the conclusion that gastro-jejunosomy should never be performed either without grave consideration beforehand or without the greatest care to make the anastomosis a perfect one.

#### CASE I.—Recurrent Gastro-jejunal Ulcer: Gastro-colic Fistula: Operations: Recovery.

In 1915 I performed posterior gastro-jejunosomy for this patient (a man) at Guy's Hospital for duodenal ulcer with stenosis. In March, 1921, I excised a small anterior gastro-jejunal ulcer which had nearly pierced the colon, and at the same time I enlarged the stoma, which had contracted. He remained well until July, 1927, when he suddenly developed a gastro-colic fistula with faecal vomiting. Some of a barium enema obviously passed into the stomach, but none of another barium enema, given a few days later. However, the diarrhoea and the other symptoms continued, therefore the diagnosis of gastro-colic fistula was made with confidence, and an operation was advised. X-ray examination showed that nearly all the food leaving the stomach passed out through the pylorus and duodenum; there was no delay in the stomach.

At the operation I found two gastro-colic fistulae; one of them admitted the index finger, the other one was smaller; both opened from the front wall of the stomach, which was of good size and position. As the duodenum was now patent and apparently healthy I excised the gastro-colic fistulae and the gastro-jejunosomy, together with the engaged loop of jejunum. This proved to be extremely difficult. The gastric wound and the distal cut end of the jejunum were closed, the end of the duodenum being implanted into the jejunum, thus restoring the normal anatomy and physiology as far as possible.

About a month later the patient was readmitted for severe hæmatemesis and melæna. The source of the bleeding was uncertain, but it was later proved to be a posterior duodenal ulcer. Careful medical treatment, with the patient in bed at the hospital, was tried in vain for three months. Duodenal stenosis gradually developed and increased so that visible peristalsis became evident in the epigastrium, and vomiting of large quantities occurred about once every forty-eight hours. Gastric lavage only afforded partial relief.

On December 8th, 1927, another operation was performed. The stomach was very dilated, hypertrophied, and inflamed, owing to a large, deep, posterior duodenal ulcer penetrating into the pancreas and stenosing the duodenum. No other ulcer could be found. A lateral gastro-duodenostomy was performed well below the duodenal ulcer. The patient made a rapid and excellent recovery from the operation, but he is to continue his extremely careful after-treatment for at least six months, and to observe all the known precautions against recurrence.

#### CASE II.—Recurrent Gastro-jejunal Ulcer: Partial Gastrectomy.

This man was referred to me for the first time early in December, 1927, with the following history. In 1908 he was explored for gall-stones; none were found, but instead a duodenal ulcer with localized peritonitis, indicating an old perforation. The appendix was removed about a year later. In 1910, the duodenal ulcer persisting in spite of medical treatment, it became necessary to perform gastro-jejunosomy. The anterior operation was performed, and the patient remained fairly well for nearly four years.

In 1914 another operation became necessary, when a large gastro-jejunal ulcer was found on the front and right side of the stomach. There was also obvious obstruction of the proximal loop of the jejunum. For these conditions entero-anastomosis was performed; this relieved the patient almost completely for nearly eleven years, then symptoms of obstruction of the stomach recurred, and a severe hæmatemesis with melæna developed.

\* Delivered at Guy's Hospital on December 15th, 1927.

Another operation was performed; the gastro-jejunostomy had contracted so much that it was necessary to detach it and make a new anterior one somewhat to the left of the old one. After this operation the patient was never well, and a month later suffered pain, and two swellings developed above and to the left of the umbilicus. These were at first thought to be ventral herniae, but later proved to be abscesses, which subsequently discharged intermittently into the gastro-jejunostomy. In June, 1927, several sinuses were excised, and they were found to lead down to the anastomosis. Two openings, one at each end of the stoma, were closed. There was also an obstruction of a loop of jejunum about a foot below the anastomosis. For this an entero-anastomosis was performed, and gave great relief, but the pain and indigestion persisted, and abscesses recurred above and to the left of the umbilicus. The pain became almost continuous, the patient thin, anaemic, and very miserable, praying for a "kill or cure" in the way of an operation.

On December 8th, 1927, the operation was performed. A large elliptical piece of the abdominal wall, containing several abscesses, was excised, together with a little more than half the stomach, the gastro-jejunostomy, the loop of jejunum engaged in the anastomosis, and a small piece of the transverse colon around a gastro-colic fistula. The operation was extremely difficult owing to numerous adhesions and the complicated anatomical conditions. As the duodenum was hopelessly stenosed and very adherent, partial gastrectomy was the only possible radical operation. The anastomosis was made after the Polya-Balfour method. The patient was so thin, and so much of the abdominal wall had been sacrificed, that it was difficult to close the parietal wound, but by beginning at each end and gradually proceeding towards the centre, and by mobilizing the parietal peritoneum, the closure was at last successfully accomplished, and the wound healed perfectly. Three pints of normal saline were run into the axillae during the operation. The next day the patient became very restless in spite of axillary infusion, and was transfused (three-quarters of a pint); this caused no reaction, but improved the patient's condition to a remarkable extent. He is now making a slow but satisfactory recovery, although an abscess developed three weeks after the operation in the right hypochondrium near a stab wound that had been used for drainage. He is now much better than he has been for several years.

#### PATHOLOGY.

A gastro-jejunal ulcer is one that forms upon the margin of the gastro-jejunostomy and involves both the stomach and the jejunum at the line of union; it may encircle the stoma, and by fibrosis it tends to narrow the opening, which may finally become completely closed, as not infrequently happened after the use of the "Murphy button." Jejunal ulcers are less common; they develop in the jejunum near the anastomosis, usually just below the stoma, or in the first four inches of the efferent limb of the jejunum, very rarely in the afferent limb. The ulcer is generally small, but it may be deep and invade the pancreas, the transverse colon, or a neighbouring coil of small intestine, into any of which it may ultimately perforate. It may also perforate into the peritoneum, causing a grave form of peritonitis, or even into the abdominal wall, causing a parietal abscess or cutaneous fistula. It may ulcerate into a large artery, such as the middle colic, and cause severe, or even fatal, haemorrhage.

#### ETIOLOGY AND PROPHYLAXIS.

The causation and prevention of gastro-jejunal ulcer are very important; certain facts bearing on these may now be considered.

Out of 270 cases at the Mayo Clinic 248 were males and only 22 were females, a ratio of eleven to one, whereas gastro-jejunostomy was performed only three times as often in men as in women. Secondary ulceration is far more likely to follow when the primary peptic ulcer is duodenal rather than gastric. Balfour<sup>2</sup> found that

"of those cases in which gastro-enterostomy was performed at the clinic, gastro-jejunal ulcer followed an operation for duodenal ulcer in 130, and followed operation for gastric ulcer in only nine. While this ratio is 15:1, the ratio between the number of cases in which gastro-enterostomy was performed for duodenal ulcer and those in which it was performed for gastric ulcer is 7:1."

These facts are significant, and tend to show that men's habits and occupations have some relation to secondary ulceration. Men are more prone to excessive smoking and drinking, and have more laborious mental and physical occupations, and generally have less leisure, with less frequent and less regular meals.

Excess of free hydrochloric acid in the stomach and in the bowel at or near the stoma has always been considered an important cause, supported by the absence of secondary ulceration (other than rare septic instances) after gastro-jejunostomy for cancer of the stomach, and the undue frequency after an operation for duodenal ulcer in which

excess of free hydrochloric acid is constant before operation, and usually after it, as shown by A. F. Hurst<sup>3</sup> at New Lodge Clinic; whereas hyperchlorhydria is rarely associated with gastric ulcer. Balfour<sup>4</sup> found that in 40 per cent. of his series of cases of gastro-jejunal ulcer

"the free hydrochloric acid was either increased or very slightly reduced by the gastro-enterostomy; but in 40 per cent. there was a marked reduction, and in 20 per cent. the free hydrochloric acid was reduced to zero. The fact that there was no free hydrochloric acid in one-fifth of the cases of gastro-jejunal ulcer, in which repeated and fractional examinations of the gastric contents were made, disproves the assumption that achlorhydria following the primary operation affords protection against later ulceration."

The hypertonic type of stomach commonly seen in the subjects of duodenal ulcer is particularly subject to recurrent ulceration, but any of the errors of habit or of sepsis which may have contributed to the causation of the original peptic ulcer, unless they are eliminated, may cause the appearance of a secondary ulcer. Notable among these causes are imperfect mastication, irregular meals, septic teeth, tonsils, sinuses, appendix, or gall-bladder. Infection from an open duodenal or gastric ulcer left behind may be grafted upon the stoma.

Anatomical and physiological errors at the stoma are important causes of recurrent ulceration. Among these may be mentioned a wrongly placed stoma, which does not drain the stomach well or obstructs the jejunum by kinking or torsion at or near the stoma; bruising or laceration of the viscera engaged in the anastomosis is to be scrupulously avoided, as also are all unabsorbable sutures. Drugs, especially tobacco and alcohol, have much to answer for in the pathogenesis of gastro-jejunal ulcer.

Errors in the after-treatment undoubtedly contribute towards the formation of gastro-jejunal ulcer. It is important for the patient to be dieted with the greatest care, and allowed only soft and non-irritating food at regular and short intervals, and to have a long restful holiday before he returns to work and worry. The slightest return of symptoms demands rest and a return to medical treatment by dieting and administration of alkalis.

#### DIAGNOSIS.

As already said, I believe that gastro-jejunal ulceration is much commoner than is generally supposed, and that it should be suspected whenever abdominal pain or "indigestion" follows gastro-jejunostomy. The diagnosis is not easy, particularly as radiography rarely gives any direct evidence of this form of peptic ulceration—that is to say, it rarely displays a shadow of the ulcer. I have only once seen such a shadow confirmed by operation. But radiography gives valuable hints—generally delay in emptying through a narrow stoma and uneasy peristalsis in the upper part of the jejunum. The symptoms are more reliable. They are similar to those of duodenal ulcer, especially hunger pain perhaps relieved by food and alkalis, but coming on much earlier than the pain of duodenal ulcer, generally within an hour after food; later it becomes more severe and almost continuous; moreover, it is above and to the left of the navel instead of in the right epigastric angle. Tenderness and perhaps a tumour are noticed in the same situation. Melæna or occult blood in the stools is very significant if the patient is on a meat-free diet. Wasting and anaemia are usually very marked. Gastro-colic fistula when present is clearly indicated by diarrhoea, foul eructations, and faecal vomiting. The early passage per anum of undigested food and the x-ray shadows after a barium enema are generally conclusive.

Occasionally a new or old duodenal ulcer, or especially a gastric ulcer, or a carcinoma supervening thereon, may be mistaken for a gastro-jejunal ulcer. In one case I mistook a gastric ulcer upon the lesser curvature, which developed some fifteen years after a gastro-jejunostomy had been performed for duodenal ulcer with stenosis and had afforded complete relief for many years. Here the pain and tenderness were naturally above and to the left of the navel, as with gastro-jejunal ulcer. The ulcer was successfully excised.

Chronic cholecystitis, pancreatitis, or appendicitis may be mistaken for gastro-jejunal ulcer, but in these conditions there is no occult blood in the faeces on a meat-free diet.

## MEDICAL TREATMENT.

The medical treatment of gastro-jejunal ulceration is far more difficult and less successful than that of any other form of peptic ulceration, but it is always worth trying a thorough course of dieting and alkalis, with complete rest in bed. Every possible source of sepsis must be carefully sought and removed. Sometimes medical treatment meets with success, but, even if it does not, it makes an excellent preparation for the surgical treatment that often affords the only hope of success. Sometimes blood transfusion on one or more occasions is necessary before an operation can be hopelessly undertaken.

## SURGICAL TREATMENT.

## 1. For Perforative Peritonitis.

As a rule the patient is so ill when he comes for treatment that all that can be done is to close the perforation and drain above the pubis. Medical treatment is then well tried, and if that fails a radical operation can be carried out later. Grant Massie<sup>2</sup> studied thirty-six recorded cases in addition to his own. The large majority (75 per cent.) of the perforating ulcers were jejunal, these being less protected than those at the anastomosis. Twenty-two of the thirty-seven patients died, so that the mortality is very high, nearly 60 per cent.

## 2. Radical Operation.\*

This may tax the skill, ingenuity, and resource of the best surgeon, owing to extensive adhesions, the obscure relations of the affected parts, and the poor condition of the patient. It is wise to insist on complete rest in bed and careful medical treatment for at least a week before the operation, which may be a difficult and prolonged one. The ideals are to excise the ulcer, provide free drainage of the stomach, and to restore as far as possible the normal anatomical and physiological conditions. The preliminary radiographic examination may have shown that nearly all the food leaves the stomach through the pylorus, and at the operation the pylorus and duodenum may be found to be patent, any previously existing ulceration having healed without causing obstruction. In these circumstances the gastro-jejunostomy should be abolished, the ulcer excised, and the opening in the jejunum closed without narrowing its channel. This should also be done when the primary operation was improperly performed for gastric symptoms without structural alteration of the stomach or duodenum. Any operation that adds further anatomical or physiological complications is to be avoided. The addition, for instance, of another gastro-jejunostomy in the hope that free drainage of the stomach may induce the ulcer to heal is doomed to failure. It is far better to excise the ulcer, although this may appear more difficult and dangerous, especially when the gastro-jejunostomy is of the posterior type. A long vertical left paramedian incision is made in the epigastrium extending below the umbilicus. The operation should commence with a rapid exploration of the abdomen, and any primary source of infection which may be discovered, such as a diseased appendix or gall-bladder, should be removed. The stomach, the duodenum, and the stoma should be carefully examined for signs of ulceration and obstruction. Dense adhesions may make this preliminary step difficult, and it is easy to overlook a small ulcer, especially on the posterior surface of the stoma.

The stoma is often narrow, and sometimes very small. Occasionally it is normal in size, but the jejunum is kinked or twisted by adhesions, so that the food, which has been shown by the x-rays to leave the stomach in a normal manner, does not pass freely along the jejunum. When the ulcer has been found the adhesions should be separated or divided, and the parts carefully freed, defined, and brought forward into the wound. This important step is often tedious and difficult, especially when the ulcer is posterior and invading the pancreas. Opening the lesser peritoneal sac and division of the posterior parietal peritoneum greatly facilitate the mobilization, but some of the invaded pancreas may have to be removed with the ulcer. A rubber cushion behind the back helps to bring forward the lumbar spine and makes the dissection easier.

Having separated, brought forward, and clamped the parts concerned in the anastomosis the most suitable treatment is more easily determined.

## (a) Simple Excision of the Ulcer.

If the ulcer is small and not encircling the stoma it is often possible to excise it and to sew up the resulting wound in such a way as to enlarge the stoma or jejunal channel. But in some cases the ulceration may recur, as in Case 1, unless all the causes of recurrence can be eliminated.

## (b) Excision of the Ulcer and Abolition of the Stoma.

If the ulcer is large or encircles the stoma, which is often contracted, it is necessary to excise the ulcerated area, thus detaching the jejunum from the stomach, and occasionally to make a new and better stoma, but if the pylorus and duodenum are healthy and patent, as often happens, it is not necessary to remake the gastro-jejunostomy; it is far better to close the openings in the stomach and jejunum, thus re-establishing the normal anatomy and physiology of the parts.

## (c) Abolition of the Stoma plus Gastro-duodenostomy.

If the original gastro-jejunostomy was anterior, it is sometimes possible to perform gastro-duodenostomy, making use of the opening left in the anterior wall of the stomach after the excision of the ulcer. The opening in the jejunum is then closed without narrowing the lumen. The result in one of my cases has remained very satisfactory for ten years. After this operation recurrence of ulceration at the stoma is very unlikely, owing to the free admixture of the alkaline duodenal secretions with the gastric juice. Similarly, when the duodenum is stenosed, after diseasing a posterior gastro-jejunostomy and closing the openings in the stomach and jejunum, a low lateral gastro-duodenostomy is made well away from the scarred or possibly ulcerated part of the duodenum. I have found this method extremely satisfactory. It is easier and better than "Finney's operation" for these cases, and it saves the patient from the more formidable operation of partial gastrectomy.

## (d) Partial Gastrectomy.

In bad cases, especially when the gastro-jejunal ulcer is recurrent and complicated, and when the duodenum is ulcerated, stenosed, or embedded in dense adhesions, it is usually wise to perform partial gastrectomy, which may be no more formidable than a less ambitious operation. It has the considerable merit of reducing the amount of the free and corroding hydrochloric acid. In order to avoid adhesions and other difficulties the stomach is divided to the left of the pylorus and its distal end is closed, a large cylindrical part of the stomach and the gastro-jejunostomy are isolated, clamped, and excised without sacrificing more of the jejunum than is absolutely necessary, so that the opening can be closed transversely without narrowing the lumen. The jejunum is then joined to the end of the cardiac remainder of the stomach after the Polya-Balfour-Moynihan method.

## (e) Closure of Gastro-colic Fistula.

When there is a gastro-colic fistula the colon is clamped, detached, and closed in two layers without narrowing its lumen; it is then covered with omentum and the removal of the gastro-jejunal ulcer is proceeded with. In one of my cases there was an additional fistula between the stomach and the ileum; this can be treated in a similar way.

## RESULTS OF OPERATIVE TREATMENT.

The formidable nature of the radical operations that are necessary for gastro-jejunal ulcer, and the thin, anæmic, and exhausted condition of many of these patients requiring it, would point to the probability of a high mortality, but as a matter of fact in good hands the mortality is not unduly high. At the Mayo Clinic<sup>3</sup> the mortality was only 3.37 per cent. in eighty-nine partial gastrectomies for this condition. The ultimate results are good and more than justify the risk of this radical operation, for "complete relief of symptoms follows the operation in more than 85 per cent. of the cases." From my

own experience I can bear out these hopeful conclusions, and I firmly believe that either restoration of the normal physiology or partial gastrectomy is necessary in most cases; the former approaches the ideal, but the latter is sometimes the only practical radical method available.

## PROGNOSIS IN PULMONARY TUBERCULOSIS.\*

BY

JOHN R. GILLESPIE, M.A., M.D., D.P.H.,

CHIEF TUBERCULOSIS MEDICAL OFFICER, CO. DOWN.

EVEN in the same community there are enormous differences in the resisting power of individuals attacked by the tubercle bacillus. At the one extreme are those who overcome the bacillus so easily that its presence in them is never suspected during life; at the other are the victims of "galloping consumption," who are very ill when first seen by the doctor, and grow progressively worse until death supervenes. Between these extremes are the majority of consumptives, whose resisting power can be fostered by appropriate treatment.

## PATIENTS WITH SMALL RESISTING POWER.

The proportion of cases in county Down in which resistance was very small (1913 to 1924) is shown roughly by the percentage of cases in which death occurred within six months of the date on which each patient was first seen by one of the tuberculosis medical officers.

TABLE I.—Percentage Dead within Six Months.

	T.B. +		T.B. -	
	Percentage.	Years of Extremes.	Percentage.	Years of Extremes.
Average ...	35.0	—	25.7	—
Maximum ...	43.2	1923	40.5	1918
Minimum ...	27.0	1913	12.5	1917

If we separate these cases into febrile and afebrile, including among the latter all cases in which the temperature ceased to exceed 99° F. after a week's rest in bed, we get Tables II and III in place of Table I.

TABLE II.—Febrile Cases. Died within Six Months.

	T.B. +		T.B. -	
	Percentage.	Years of Extremes.	Percentage.	Years of Extremes.
Average ...	49.3	—	43.3	—
Maximum ...	61.5	1922	59.1	1922
Minimum ...	41.2	1914	25.0	1917

TABLE III.—Afebrile Cases. Died within Six Months.

	T.B. +		T.B. -	
	Percentage.	Years of Extremes.	Percentage.	Years of Extremes.
Average ...	12.8	—	8.1	—
Maximum ...	22.0	1915	37.0	1918
Minimum ...	0	1917	0	1915 1917 1922

Since the percentage of rapidly fatal cases found in different years varies so much, we should be chary about

\* An abridgement of a paper read before the Belfast Division of the British Medical Association.

coming to a conclusion as to the efficacy of any remedy intended to reduce this percentage, until it has been tried in a large number of cases spread over a considerable number of years.

Almost without exception the patients who died within six months were considered too ill either to be sent to a sanatorium or to be treated at a tuberculosis dispensary. Arrangements were therefore made for domiciliary treatment, the patient being instructed to stay in bed as long as the temperature exceeded 99° F. at any time in the day; to have a room to himself; to admit as much fresh air and sunlight as possible into his room; and to take as much plain nourishing food of various kinds as his stomach would allow.

Where satisfactory home conditions were not available the patient was advised to go into the union infirmary. No special treatment, such as artificial pneumothorax, was tried in any of them. As there is no county sanatorium in county Down, and the sanatoriums to which we sent patients were unwilling to take bad cases, this was the best we could do.

## Recent and Non-recent Cases.

In 52 per cent. of our cases (1913 to 1924) the patients had been ill for more than six months before the tuberculosis medical officer was called in, and in 48 per cent. for less. Counting the latter as recent cases, and the former as non-recent, we get the following four tables.

TABLE IV.—Recent Febrile Cases. Died within Six Months.

	T.B. +		T.B. -	
	Percentage.	Years of Extremes.	Percentage.	Years of Extremes.
Average ...	49.8	—	43.4	—
Maximum ...	63.2	1919	67.2	1922
Minimum ...	32.2	1916	22.2	1917

TABLE V.—Non-recent Febrile Cases. Died within Six Months.

	T.B. +		T.B. -	
	Percentage.	Years of Extremes.	Percentage.	Years of Extremes.
Average ...	48.6	—	43.0	—
Maximum ...	64.3	1922	68.8	1923
Minimum ...	31.2	1913	12.4	1913

TABLE VI.—Recent Afebrile Cases. Died within Six Months.

	T.B. +		T.B. -	
	Percentage.	Years of Extremes.	Percentage.	Years of Extremes.
Average ...	8.8	—	5.0	—
Maximum ...	27.4	1920	19.8	1918
Minimum ...	0	1915 1916 1917 1919 1924	0	1915 1917 1919 1922

TABLE VII.—Non-recent Afebrile Cases. Died within Six Months.

	T.B. +		T.B. -	
	Percentage.	Years of Extremes.	Percentage.	Years of Extremes.
Average ...	15.8	—	10.2	—
Maximum ...	53.4	1915	50.0	1918
Minimum ...	0	1917	0	1915 1917 1922 1924

Taking the average figures from Tables IV, V, VI, and VII as a basis, we can now classify the cases in the order of good prognosis as regards immediate danger as follows:

TABLE VIII.—Percentage of Patients who Died within Six Months.

	T.B. —	T.B. +
I. Recent afebrile patients ... ..	5.0	8.8
II. Non-recent afebrile .. .. .	10.2	15.8
III. Non-recent febrile .. .. .	43.0	48.6
IV. Recent febrile .. .. .	43.4	49.8

From this table may be seen the wisdom of Professor Moellgaard and Dr. Faber in asking that sanocrysin be used only in afebrile exudative cases. By exudative cases they mean cases in which there has been proliferation of cells rather than formation of fibrous tissue in the affected parts of the lungs. This is the condition to be expected in recent cases. Hence afebrile exudative cases are very much the same as recent afebrile cases. These are the cases in which the best results are to be expected, whatever form of treatment be used.

#### Extent of Disease as Revealed by Physical Signs.

Up to this point no account has been taken of the extent of the disease in the lungs, as revealed by physical signs. This is an important consideration. At the first examination of each of the patients the case was classified according to the Turbau-Gerhardt rules, the symbols T.G. 1, T.G. 2, and T.G. 3 being employed to indicate the extent and severity of physical signs. The effect of a further subdivision of the cases according to this consideration is shown in Table IX.

TABLE IX.—Percentage of Patients who Died within Six Months; Average of Twelve Years.

	T.G. 1 and 2.		T.G. 3.	
	T.B. —	T.B. +	T.B. —	T.B. +
Afebrile: Recent ... ..	3.2	5.4	8.2	14.5
" Non-recent ... ..	5.3	5.3	13.4	20.0
Febrile: Non-recent ... ..	23.2	26.7	54.0	55.1
" Recent ... ..	33.9	38.0	47.7	54.7

From this table we may calculate the probability that in any particular case of pulmonary tuberculosis death will or will not occur within six months.

#### Pulse Rate.

The pulse rate is a very important item not yet taken into account. I have not been able to work it in numerically. Most febrile cases can be rendered afebrile by rest in bed if the pulse rate be normal, or not much above normal. If the case be febrile, and the pulse rate 120 or more, the outlook is very grave. The pulse rate, however, may be considerably higher in the presence of the doctor than in his absence. This applies particularly to the first visit. The temperature, too, is similarly affected in some cases.

#### PATIENTS WITH MODERATE RESISTING POWER.

Let us now consider the after-history of the patients who survived more than six months after they were first seen by one of the tuberculosis medical officers. The number of these was 1,266, of whom 743 had tubercle bacilli in their sputum and 523 had not. There was a very great difference between these two groups, both as regards restoration of working power and mortality. There was also a distinct difference in these two respects in each of these T.B. + and T.B. — groups, according to the method of treatment.

Three methods of treatment were available: (1) dispensary, where tuberculin was used in all cases, according to what I have called in a previous paper "a rational

method"; (2) sanatorium, where tuberculin was used in very few cases, and then only by a rule-of-thumb method; and (3) domiciliary.

No case was classed as treated at dispensary or sanatorium unless at least three months' treatment had been received at one or the other. Patients who received tuberculin treatment from their own doctors under the direction of the tuberculosis medical officer are classed with those treated at the dispensary. To avoid confusion, cases in which three or more months of dispensary treatment was received as well as three or more months of sanatorium treatment are not included in Table X, which illustrates what has just been said.

TABLE X.—After Ten Years.

Mode of Treatment.	Percentage at Work after Ten Years.		Percentage Dead after Ten Years.	
	T.B. +	T.B. —	T.B. +	T.B. —
Dispensary ... ..	19.2	70.0	72.0	21.0
Sanatorium ... ..	11.8	67.0	88.2	33.0
Domiciliary ... ..	2.4	44.4	94.1	53.3

No attempt was made to select better cases for dispensary treatment than for sanatorium, nor vice versa. Those who were fit for the one were generally fit for the other, and the choice was left with the patients.

The exclusion of the cases in which death occurred within six months of the time when each patient was first examined by a tuberculosis medical officer left the third group not very different, to begin with, from the other two.

It is noteworthy that even among patients who had tubercle bacilli in their sputum, and who did not receive either dispensary or sanatorium treatment, 2.4 per cent. of those who survived the first six months were at work after ten years. If, therefore, we are shown one or more patients who have done well under some form of treatment, and are asked to believe in consequence that this form of treatment is efficacious, we should hesitate to come to a conclusion until we know what proportion of the patients so treated have done well, and how long they have continued well, separating T.B. + from T.B. — cases. Among the latter 44.4 per cent. of those who survived the first six months were at work after ten years without any special treatment.

Table XI illustrates the effect on recovery and maintenance of working power of (1) the presence or absence of tubercle bacilli in the sputum; (2) the extent of the disease in the lungs as revealed by physical signs; and (3) the mode of treatment. In this are included all the cases diagnosed as pulmonary tuberculosis in the thirteen years 1913-25, except (1) a few that could not be traced, (2) cases where death occurred within six months from the time when the patient was first examined by a tuberculosis medical officer, and (3) cases in which both dispensary and sanatorium treatment were received for three or more months each.

The figures in the table represent the percentage in each section who were at work in March, 1927. The average time that had elapsed since the patients were first seen was thus eight years.

TABLE XI.—Patients first seen in years 1913-25. Percentage at Work in March, 1927.

Mode of Treatment.	T.B. —		T.B. +	
	T.G. 1 and 2.	T.G. 3.	T.G. 1 and 2.	T.G. 3.
Dispensary ... ..	82.6	68.9	37.1	9.6
Sanatorium ... ..	50.0	41.7	15.5	6.6
Domiciliary ... ..	55.0	40.1	11.3	4.4

These figures, as well as those in Table X, confirm me in the opinion that tuberculin, when rightly used, is of distinct service in the treatment of pulmonary tuberculosis.

CHRONIC HEADACHE AND PAIN IN THE EYES  
RELIEVED BY A NASAL OPERATION.

BY

ROSA FORD, M.B., D.O.,

OPHTHALMIC SURGEON TO THE SOUTH LONDON HOSPITAL FOR WOMEN.

ALTHOUGH there is nothing new in the relief of pain by a nasal operation, the three following cases are reported because the indications for the operation were so indefinite, and the diagnosis so obscure, that the three patients had sought medical relief, many times, in vain.

## CASE I.

An unmarried woman, a teacher, aged 32, had suffered from frontal headache for ten years, and from pain behind the left eye and along the nose to the tip for one year. In addition, she had often been off work for general debility. On several occasions a "tired heart" had been diagnosed, and she was particularly troubled by the alteration in her mental condition. She sometimes, for example, felt unable to reply to a tradesman calling at the door, could not concentrate, or had a "sense of fear." She left town for the country, and finally for New Zealand, on account of the "troublesome pressure" in her head, and had returned on holiday when I saw her. There was nothing in the eyes to account for the pain. Glasses had failed on three occasions to relieve her, and there was no muscular imbalance. There were, however, two clues—the patient's past history and the fields of vision.

1. *The Past History.*—She had had post-nasal catarrh, certainly since the age of 14, and probably four years earlier, when she had measles. As a child she always had colds in the head, had suffered from frontal headaches and "muddled head," and was seldom clear-headed. At 19 she was using fifty handkerchiefs a week. At 22 part of the left middle turbinate was removed, and this reduced the catarrh, so that she afterwards only soaked two handkerchiefs before breakfast, the discharge coming mostly from the left side of the nose. But the operation was followed by the frontal headache, from which she continued to suffer for ten years.

2. *The Fields.*—Both blind spots were slightly enlarged, and the left had a large relative extension outwards. The fields were contracted, especially the left.

These two clues led to a diagnosis of sinusitis as the cause of the pain in the head and eyes, the post-nasal catarrh, and the field changes. To confirm this diagnosis the sinuses were x-rayed, but with a negative result. An aural examination showed left ethmoiditis, but operation was not advised. Local treatment was ordered and followed for some weeks, but, as the pain continued, the patient pressed for further advice, and a second aural surgeon found septal tonsils and a high septal deviation to the right. There was no pus. A second x-ray examination was also negative, though the aural surgeon thought there was a slight dullness of the left ethmoid.

The tonsils were enucleated and a partial submucous resection was performed. Before leaving the nursing home the patient wrote: "That miserable pressure has been entirely removed, and my head is as clear as day and my eyes are splendid." A month later she was still free from pain; she said that her mental condition had been entirely normal since the operation, and that the catarrh had practically ceased. Her blind spots were normal, the relative scotoma about the left blind spot had disappeared, and the fields were almost full. Eleven months later she wrote from New Zealand that she was "much better in every way and improving all the time."

## CASE II.

An unmarried woman, a nurse, aged 52, had suffered for eleven years from left frontal headache, with vomiting, and from pain at the back of the left eye for four years. During the last two years the left eye had ached almost incessantly. In addition, she was constantly tired, and felt her mental powers so diminished that she finally decided to give up her post.

There was nothing in the eyes to explain the pain. Glasses had failed several times to relieve her, and there was no muscular imbalance. The clues were extremely few and vague. No symptoms at all of nasal disease could be elicited.

1. *The Past History.*—At the age of 13 there had been a seven months' illness, commencing with measles and pneumonia and ending with "typhoid," in which the eyes and nose had been "very bad." Since then her life had been a long succession of septic infections—continual dental abscesses from the age of 14 to 26, carbuncles at 27, colitis, and a "murmur removed from the left breast at 39, central choroido-retinitis first removed at 45, carbuncles again at 50. This history suggested the possibility of sinusitis, commencing at 13 and continuing as a septic focus, giving no evidence of its existence except in the secondary infections which arose from it.

2. *The Fields.*—Both fields were contracted bitemporally. The left blind spot was enlarged, with considerable relative extension. The right blind spot was normal, with slight relative extension.

On these grounds a tentative diagnosis of sinusitis was made. A first aural and x-ray examination proved negative. Later on, a second x-ray examination was also negative, but Mr. Gill-Carey, who kindly examined her for me, found high septal deviation to the left and tenderness of the floor of the left frontal sinus. There was no evidence of pus, and an operation was not advised.

On x-ray evidence all the teeth were then extracted, and two months' rest taken afterwards in the country. At the end of this time the pain was worse, and the aural surgeon agreed that operation was advisable. A portion of the anterior end of the middle turbinate was removed. Nine days later the pain had entirely gone from the left eye and she was practically free from headache. Two months later there had been two headaches, but no eye pain, and the head had been "marvellously better." Vision was misty at times, and this, with the incomplete freedom from headaches, led Mr. Gill-Carey to suggest the removal of a further piece of turbinate. This was done, and at the same time, in view of the long septic history, the tonsils were enucleated. Two months later there had been only one headache, after a cold. The fields had widened to some extent, especially the right.

Obviously the cause of the headache had been reached, though the result seemed less complete than in the other two cases, in which a resection of the septum was performed.

The sinuses in this case were punctured, washed out, and the washings cultured. The right sphenoid was sterile, but from both ethmoids were recovered *Streptococcus longus* and *Staphylococcus albus*, and the left sphenoid gave a growth of *Staphylococcus albus*. Culture from the tonsils produced a bacillus of the Friedländer type and *Streptococcus longus*.

## CASE III.

An unmarried woman, a nurse, aged 44, had suffered from vertical headache and aching of the eyes for three years. The headache had begun quite suddenly, without apparent cause. She had consulted two other oculists, each on two occasions, without relief. In addition, she was "frightfully tired," "hopelessly depressed," and could not rely on her mental powers—for example, when playing bridge there would be intervals when her mind was a blank, so that she could not continue the game.

There was no cause in the eyes for the pain. Glasses had failed many times to relieve her, and there was no muscular imbalance. Again there were two clues—one in the past history and the other in the fields of vision.

1. *The Past History.*—(a) She had suffered from post-nasal catarrh all her life. In infancy there had been two severe illnesses, of which no details were available. Possibly the catarrh originated in one of these. (b) Eleven years previously she had had a septic throat, for which she had been off duty for six weeks. Before this she had considered herself a healthy woman, after this she was never really well, and at the age of 41, eight years after the throat infection, her health was so impaired that she was obliged to give up work.

2. *The Fields.*—Both were markedly contracted for small objects, and the right blind spot was decidedly enlarged.

These clues led to the following interpretation of the case. In infancy some illness had started a sinusitis, of which at first the only evidence was post-nasal catarrh, although the rheumatism and bad teeth, from which she had suffered from her earliest recollections, were probably secondary infections from the focus in the sinus. The general health was not further affected, because drainage was free. At the age of 33 the septic throat caused an exacerbation of the sinusitis and increased the block to drainage, so that septic absorption increased, with consequent ill health. At 41 a further inflammatory increase of the block to drainage closed the sinuses still more, leading to tension within them, and thus to headache and pain round the eyes.

Radiological examination proved negative, but a high septal deviation to the right was found, with compensatory left middle turbinate enlargement, and chronic inflammatory changes in the left nasopharynx. There was no evidence of pus. Mr. Gill-Carey resected the septum on December 1st, 1927. Some nasal discharge receded, but by December 26th this had ceased. There has been: no pain in the head or eyes now for three months. The fields taken on January 24th, 1928, show a practically full field, even for small objects (1/2000 white). The right blind spot (20/2000) is about the same, but the increase for a 1/2000 white object is only slight.

The patient's mental condition is normal. She can play bridge with zest, is only occasionally depressed, and is able to take a keen interest in life generally.

## Comment.

The following comments mainly refer to rhinological matters, but in the study of these cases on the border-line between two specialties it has been necessary often to step over the border. However, Mr. Gill-Carey has discussed and agrees with the conclusions reached.

*Diagnosis.*—In cases such as these, which are by no means uncommon, the indications of the actual lesion are often extremely indefinite. The best clue is generally to be found in the past history. The fields may be of increasing help when further experience has been gained in this type of case. Culture of sinus washings may also give considerable assistance with further experience of this method. Radiological examination is sometimes of value, but a negative x-ray report does not exclude sinusitis. The absence of pus in the nose (as in all three cases), and even the entire absence of nasal symptoms (as in one case), must not exclude a diagnosis of sinusitis.

*Etiology.*—In the three cases the sinusitis probably started in early childhood with some illness—for example, measles—and had continued more or less latent, causing profound debility and various septic conditions, which

increased as life went on, during 22, 39, and 42 years, inducing a stage of acute misery.

All the patients had a high septal deviation, which was probably the reason why the sinusitis originally failed to resolve.

**Cure.**—The removal of a piece of bone from the nose, followed in a few days by complete relief of symptoms, is a dramatic ending to these long-drawn-out histories of pain and disease, accompanied by so much disability and acute mental anxiety. The possibility of so simple a cure makes it very desirable to devise means whereby an earlier diagnosis may prevent rather than cure such misery.

**Prevention.**—Childhood's diseases—for example, measles, scarlet fever, diphtheria, and whooping-cough—in which there is commonly acute nasal inflammation, are apt to leave behind them a chronic infection of the sinuses, of which there may be local evidence in "constant colds" and post-nasal catarrh, or the child may show only a general debility, with few or no symptoms of nasal infection. There may, however, be evidence of septal absorption or retention—for example, constant sties, spots on the skin, headaches, rheumatism, and bad teeth; this latent sinusitis may continue to be pathological throughout the rest of life. The main method of prevention, therefore, will be the adequate treatment of these childish diseases and their after-effects.

Since it is probable that, had there been no septal deviation, the sinusitis would have healed in the ordinary course, the persistence of symptoms of sinusitis in a child, in spite of the removal of soft tissues—for example, tonsils and adenoids—suggests a bony obstruction to drainage, the removal of which, unless contraindicated, would save much present and future suffering.

Post-nasal catarrh, even when it has continued so long that the patient has become resigned to it and considers it of no significance, remains nevertheless a constant potential danger.

These cases are not primarily ophthalmic, yet patients and their doctors naturally seek first the help of ophthalmic surgeons, as all of these did, and must rely on them to distinguish these cases from those due to refractive or muscular error.

With such indefinite radiological and clinical signs the rhinologist hesitates to operate, and looks to the ophthalmologist to strengthen his hands. It may be that, with further experience, the fields will enable us, in certain cases, to give a decided opinion.

## AN UNUSUAL CASE OF FOOD POISONING.

BY

F. M. ROWLAND, C.B.E., F. W. MARSHALL, M.B.,

AND

J. MENTON, L.R.C.P. AND S.I.,  
BACTERIOLOGIST, COUNTY OF STAFFORD.

THE causation of attacks of food poisoning has for many years been a thing of mystery to the average practitioner, and even for the expert there are many points in the epidemiology and bacteriology of the condition which are still far from clear.

The proof that the infective organism in the case here recorded was *B. aertrycke* was entirely due to the pathological findings, for the clinical aspect was distinctly equivocal. In view of this and the sporadic nature of the case, we felt justified in recording it. The history of the illness is as follows:

A married woman, aged 24, was first seen on September 19th, 1927, and gave a history of having had a rise of temperature ( $99^{\circ}$  to  $101^{\circ}$  F.) at night for the previous three nights, with a subnormal temperature each morning. She had been going out each day, but complained of epigastric pain and occasional vomiting. There was a history of a fall on the back of the head four days previously, but without loss of consciousness or immediate subsequent vomiting.

When first seen her chief complaint was of severe occipital headache and of "rheumatic" pains in various parts of the body, especially in the back of the neck on the left side. There was creaking in the left temporo-mandibular joint and she

complained of fleeting pains in the hips on movement. There was no diarrhoea and the bowels were acting normally; the appearance of the motions was normal. There was marked hyperaesthesia over the epigastrium, and also, to a less extent, over each renal region. Even the slightest pressure over the epigastrium caused a feeling of nausea; the tongue was clean.

She was given salicylates and aspirin without marked improvement, the temperature still rising at night ( $101^{\circ}$  to  $102^{\circ}$  F.) and being subnormal in the morning. The possibility of pyelitis was considered, but the urine was acid, contained no albumin, and microscopic examination showed nothing abnormal.

On September 22nd she complained of nausea and occasional vomiting, which latter rapidly became more persistent and uncontrollable, with increasing epigastric pain, especially after swallowing. There was marked tenderness on palpation over the spleen, but at this stage the spleen itself could not be felt.

On September 28th she was seen in consultation with Dr. T. L. Hardy of Birmingham, and the case was regarded as clinically suggesting paratyphoid fever. The long axis of splenic dullness was slightly increased and the spleen was just palpable. The white blood corpuscles were 5,800 in number, and a differential count showed polymorphs 29.5 per cent., lymphocytes 59.5 per cent., mononuclears 10 per cent., eosinophils 1 per cent. A serological investigation at the county laboratory on this date revealed the presence of 1 in 25 agglutinability to *B. aertrycke* Mutton, and complete absence of agglutinins to *B. typhosus*, to *B. paratyphosus* A, B, and C, to *B. enteritidis* Gaertner, *B. aertrycke* Newport, and to the dysentery group.

On September 29th, as a result of the blood examination, the patient was closely questioned as to any article of food she had had which might have caused food poisoning, although previously no suspicion of this had been entertained. The fact was elicited that four days before the onset of the illness she had partaken of some pork pie, and that three other members of the household who had also partaken had suffered from slight malaise, nausea, and vomiting from one to three days after this meal.

The patient's vomiting gradually became less distressing and was eventually controlled by minute doses of tincture of iodine and by glucose by the mouth. Two days later she developed a follicular tonsillitis, but this quickly cleared up with ordinary remedies.

A further sample of blood was taken on October 3rd and gave a similar result to the previous one; a blood culture proved negative. By this time an organism had been isolated from the faeces which gave the cultural reactions of a member of the Salmonella group. It displayed marked flocculation in a dilution of 1 in 25 with *aertrycke* serum (Mutton type) in less than two hours' incubation in the water bath at  $56^{\circ}$  C., but showed no agglutination with paratyphoid serum after four hours' incubation and standing all night at room temperature. The specific serums for Gaertner's bacillus and for *B. aertrycke* (Newport type) failed to cause any agglutination. When tested against the patient's serum marked flocculation was produced in a dilution of 1 in 25, and granulation was evident in 1 in 50. Highly specific standardized cultures and serums were used throughout, and the diagnosis was fortunately simplified by the absence of confusing conglutinins, both in the investigations on the patient's serum and in those necessary to establish the identity of the micro-organism.

The interesting and unusual points of this case appear to be: (1) A food poisoning which spent itself upon the upper intestinal tract without giving rise to any diarrhoea or signs of enteritis. (2) The slightly enlarged spleen, which, together with the pyrexia and the blood picture, gave rise to a suspicion of paratyphoid infection. (3) The nocturnal rise of temperature—on one occasion it was as high as  $103^{\circ}$  F.—which is a very unusual feature of food poisoning cases.

So far as could be ascertained there are a few cases on record which bear much resemblance to the case described. In the majority of recorded cases the onset has been acute, with diarrhoea and vomiting, and has therefore at once led to the suspicion of food poisoning. A search of the literature, however, brings several interesting points to light.

Drs. Perry and Tidy's report on an epidemic caused by the Newport strain of *B. aertrycke* occurring in a depot in France. These authors describe two clinical types: Type A, characterized by high temperature, general malaise, various pains, but no diarrhoea; Type B, characterized by diarrhoea and vomiting and a normal or slightly subnormal temperature.

It is interesting to note that in Type A the stools from nearly a hundred cases were examined, but in one case only was a bacillus found resembling *B. aertrycke*. The authors therefore concluded that this group was not connected with an infection due to *B. aertrycke*, and was, in fact, an entirely separate epidemic. Nevertheless, it is tempting to suggest that the case above described might quite easily have been classed in Type A, but in no circumstances could it have been classed in Type B.

In Type B the onset was sudden, with abdominal pain

and diarrhoea. Vomiting was common, and chills, sweats, and headaches frequent. In most cases the initial symptoms were the severest, and the patient rapidly improved. The duration of the diarrhoea varied from a few hours in the milder cases to four to seven days in the severest ones. Headache was rare after the first day. In the majority of this group vomiting occurred at the outset, and continuation of the vomiting was the most serious symptom encountered. Pyrexia was unusual, even in the severest cases, and the temperature was often subnormal. There was no splenic enlargement or rash.

These authors conclude, therefore, that the disease varies from an acute gastro-enteritis to a mild diarrhoea. The onset is sudden and pyrexia is exceptional. The course has no resemblance to enteric fever, and the character of the stools is unlike dysentery. They also consider that the infection in this epidemic was by carriers, either acute or chronic.

Dr. Pleasance<sup>2</sup> describes a sporadic case of *B. acertrycke* infection occurring in a boy aged 3. The onset was very acute, with severe diarrhoea and vomiting; death occurred on the seventh day. *Post mortem* a large splenic abscess was found. Subsequently a Gram-negative, actively motile bacillus was isolated in pure culture from the gall-bladder and splenic pulp, but when first isolated the organism was not agglutinated by the specific serums for *B. paratyphosus* B or *B. acertrycke*. Repeated subcultures were made, and twelve months after isolation the organisms agglutinated with *B. paratyphosus* B and *B. acertrycke* antiserums. Absorption tests were then performed and the organism identified as *B. acertrycke*. This illustrates the fact that *B. acertrycke* can at times assume invasive powers, and it is possible that in the case here recorded this occurred to some extent, since from the signs and symptoms it is evident that the organism was not confined to the alimentary tract.

An epidemic is described by Dr. Burgess<sup>3</sup> comprising 703 known cases. The incubation period was two and a half to twenty-four hours, and the onset was very sudden, with pain, vomiting, and diarrhoea. There were also pyrexia, headaches, chills, and sweats. The diarrhoea was very severe. The acute stage is stated to have lasted two to ten days, but the average was four to five days, and convalescence was rapid. The outbreak was traced to cream used in the manufacture of cream cakes, and the organism isolated was *B. acertrycke*.

It will therefore be seen that, with the exception of Perry and Tidy's Type A, all the cases described by these authors had an acute onset with diarrhoea and vomiting, and as a rule pyrexia was not a marked feature of the condition.

Dr. Savage and Mr. Bruce White<sup>4</sup> consider that *Salmonella* food poisoning is due, in the majority of instances, to *B. acertrycke*, and they assert that, in this country at least, this organism is responsible for three-quarters of the outbreaks. These authorities point out that they have failed to find any evidence of the ability of *B. paratyphosus* B to produce an ordinary attack of food poisoning, though they admit that paratyphoid fever may at times have a sudden onset which may temporarily simulate it. The converse is, however, illustrated by this case, in which at the onset the irritation symptoms so characteristic of *B. acertrycke* infection were so slight as to lead for a short time to a tentative diagnosis of paratyphoid fever.

Not infrequently the serums of patients suffering from *B. acertrycke* infection show coagglutinins for *B. paratyphosus* B. If such serums are sent for diagnosis for typhoid or paratyphoid fever, and if the investigations are restricted to the diagnosis of these infections, it may happen that such coagglutination may lead to a wrong diagnosis of paratyphoid fever; or if, as in the present case, coagglutinins are absent, a negative result for the typhoid-paratyphoid group is worthless. We therefore strongly urge that when sending blood samples to a laboratory for examination when typhoid or paratyphoid fever is suspected, and more especially when the clinical signs and symptoms are not typical, a full investigation as regards the *Salmonella* group and the associated organisms should be required; when multiple agglutinins occur their relative

importance must be established by absorption tests. We have reason to suggest that, should such comprehensive agglutination tests be more generally adopted, sporadic cases of *B. acertrycke* infection will be found to be more frequent.

We should like also to emphasize the importance of the bacteriological examination of the faeces in every case, as the isolation of the organism definitely clinches the diagnosis. This, however, takes some time and, provided that proper cultures and technique are utilized, examination of the patient's serum in the first instance is a valuable aid to rapid diagnosis; it may help in tracing the source of the infection, which may not be available by the time the organism has been recovered and proved.

To a few workers these statements may appear commonplace, but we know from our own experience and that of others that in routine work, both clinical and bacteriological, the *Salmonella* food-poisoning organisms are seldom considered, except when a typical and serious outbreak forces them on our attention.

## A COMPARISON OF THE WASSERMANN, KAHN, AND SIGMA TESTS.

BY

T. E. OSMOND, M.B.CANTAB.,

PATHOLOGIST, VENEREAL DISEASES DEPARTMENT, ST. THOMAS'S HOSPITAL, LONDON.

For this purpose 2,019 serums were taken and submitted to all three tests. The greater number were from cases of treated syphilis. The remainder included cases in which the diagnosis was clinically doubtful and cases in which the first test carried out gave a doubtful result or one contrary to the clinical findings.

## Technique.

The Wassermann test was No. 1 method, as described in the Medical Research Council, Special Report Series No. 14. Results were recorded as ++; +; ±; -; and negative. For diagnostic purposes + was considered positive and ± doubtful (in treated cases ± = positive).

The Kahn test was carried out as laid down by the author,<sup>1</sup> but after the first few tests the first tube of each was omitted and only two tubes used—that is, those containing 6 and 12 parts of serum respectively to 1 of antigen. Results were read by artificial light with a ×6 hand lens, and were recorded as positive (P), negative (N), or doubtful (D), one letter being employed for each tube.

Positivo is indicated by P P, but a D P result was considered positive in cases under treatment. D D = doubtful and N N or N D = negative.

The Sigma test was carried out as described in the Medical Research Council, Special Report Series No. 78; only five tubes were used, and the reading was taken at from twenty to twenty-two hours. A reading of 1.5 units and upwards was taken as positive, 1 to 1.5 as doubtful (positive in treated cases), and below 1 as negative.

Of the 2,019 serums examined 1,401 showed absolute, and 403 relative, agreement with all three tests, which is almost 90 per cent. Of the 215 serums which showed disagreement 205 were from cases of syphilis, either treated or untreated. Of these 205:

The Kahn test appeared to be most correct in	72
Wassermann	32
"	5
" Sigma	57
" Kahn and Sigma	31
" Kahn and Wassermann	8
" Sigma and Wassermann	

Thus it would appear that the Kahn was most correct 160 times, the Wassermann reaction 71 times, and the Sigma test 70 times.

Of the remaining 10 there were 6 apparently false Kahn tests. In 2 there was agreement with the Wassermann

reaction, in 1 agreement with the Sigma, in 1 partial agreement with the Sigma, and in 2 partial agreement with the Wassermann reaction. False positives may therefore be reduced to 3 (in 2 of which the readings were N P, P, and D P P respectively). There were 6 apparently false positive Wassermann reactions. In 2 the Kahn agreed; in 2 the Kahn partially agreed; in 1 the Sigma partially agreed, and one case was probably syphilis. There were thus 3 "false positives," which gave the following readings:  $\pm$  (test repeated with the same result),  $+$  (test repeated with the same result), and  $+$ . There was 1 apparently false positive Sigma test with which the Kahn agreed.

#### Conclusions.

From the above it would appear that whilst there was a high percentage of agreement between the three tests the results were slightly, but definitely, in favour of the Kahn. It is not suggested that this test could or should replace the Wassermann, but it is a very useful additional test, especially in cases where the diagnosis is in doubt

or where the Wassermann reaction gives a  $\pm$  result. The Kahn test appears to give a definitely greater proportion of positives in cases of treated syphilis; in other words, it remains positive longer than the Wassermann during treatment. It is probable that had the Sigma tests been carried to the full incubation period of forty to forty-four hours a greater number of positives would have been obtained, but this was not done on account of the extra time involved and consequent delay.

The chief advantage of the Kahn test is its simplicity. It does not require as many ingredients as the Wassermann nor the complicated titrations; it is much more rapidly carried out than the Sigma with its somewhat elaborate apparatus. A reliable result of a Kahn test can be given within an hour of receiving the serum.

I have to thank Colonel L. W. Harrison, D.S.O., F.R.C.P.Ed., Director of the Veneral Department, St. Thomas's Hospital, for permission to publish these figures.

## A COMPARISON OF THE EFFICIENCY OF SOME METHODS OF OXYGEN ADMINISTRATION.

BY

R. HILTON, M.A., M.B.,

CHIEF ASSISTANT, MEDICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL.\*

ANOXAEMIA has been classified by Barcroft<sup>1</sup> as follows: (1) Anoxic, when the blood has failed to pick up its proper load of oxygen in the lungs, so that its oxygen pressure is too low; (2) anemic, when the blood has picked up all it can carry, so that its oxygen pressure is normal, but owing to deficiency of haemoglobin its load is not sufficiently great; (3) stagnant, when the oxygen in the arterial blood is normal, but the flow through the capillaries is too slow.

It is in the anoxic type that oxygen administration is especially indicated, as occurs, for example, in lobar pneumonia.

#### Methods.

Accounts of the different methods which are in use have been given by numerous authors.<sup>2,3</sup> The methods studied in this paper are (a) the tube and funnel held closely over the mouth and nose, and

(b) at a measured distance; (c) a nasal catheter inserted in one nostril, with its end in the nasopharynx; (d) the Haldane mask; (e) a new mask over the mouth only.

The basis of comparison chosen is the pressure of oxygen in the alveolar air of a normal subject breathing at known rate and depth. Only respiratory methods of administration are mentioned here, because intravascular ways are considered dangerous and subcutaneous injections useless in view of the small amount that can be absorbed in comparison with the bodily needs.<sup>10</sup>

#### Findings.

Chart 1 shows that up to 4 litres a minute, given by a funnel held 10 cm. from the mouth, has no effect on the alveolar oxygen pressure. If, however, the funnel is pressed closely over the nose and under the chin the effect obtained is about the same as with a nasal catheter at the same rate of flow of oxygen. For example, oxygen given at 1½ litres a minute will raise the alveolar oxygen pressure half as much again as when breathing air, whereas 3 litres will double it.

Chart 2, which is on a smaller scale, shows in addition

the alveolar oxygen when the Haldane mask is used. The figures here shown for the catheter and mask do not differ materially from those already published.<sup>6</sup> Mention will be made later of the results obtained with the mouth-mask.

#### Comment.

It is incontestable that the face-mask method is a very efficient means of raising the alveolar oxygen; but every physician knows the clinical objections to the prolonged use of a mask which covers the mouth and nose. The reasons for a patient's intolerance may be physiological, such as slight obstruction to breathing, or an increase of the dead space with consequent rebreathing of a fraction of the expired air; it would seem that the reasons are also psycho-

logical, for even a normal person without dyspnoea feels hot and uncomfortable after wearing a mask for a few minutes. The nasal catheter is therefore used as a compromise. Against its manifest inferiority in raising the alveolar oxygen pressure must be set the fact of its simplicity and convenience both to patient and doctor. "It can even be used in children."<sup>11</sup> By its use oxygen administration can be continued for days on end, uninterrupted by the necessity of feeding, by coughing, or by sleeping. We have shown its effect on the alveolar oxygen. That this effect may be great enough to improve the oxygenation of the blood in lobar pneumonia is seen from the following cases.

Case 1.—Male, aged 44; respirations 42, pulse 125. The oxygen saturation of the arterial blood before giving oxygen was 85 per cent. Rate of flow of oxygen was 0.75 litre a minute by nasal catheter for fifteen minutes. The oxygen saturation was raised to 89 per cent.

Case 2.—Male, aged 50; respirations 35, pulse 112. The oxygen saturation of the arterial blood after having 0.5 litre of oxygen a minute by catheter for two hours was 80 per cent. The rate of flow was then increased to 1 litre a minute. Fifteen minutes later the oxygen saturation had risen to 88 per cent.

The rates of flow used in these two cases were, for experimental reasons, much below what should be employed. In pneumonia the flow should be slowly increased to at least 3 litres a minute. The catheter generally used in adults is a No. 9 oesophageal. The lateral hole should be near the tip; the terminal four inches are smeared with cocaine ointment, and the catheter is inserted into one nostril until a resistance is felt, when it is withdrawn slightly. If there is no obstruction in the nose the end should now be in the nasopharynx. The patient is more

CHART 1.

CHART 1.—Shows that oxygen given by a funnel held 10 cm. from the mouth does not enrich the alveolar air. Subject breathing 350 c.c.m. per breath; respirations 15 a minute. (240 mm. is about equal to 33 per cent. oxygen in alveolar air.)

CHART 2.—(a) and (b) show pressures obtained with the new mouth-mask. (a) With the nostrils closed by cotton-wool. (b) Breathing air by the nose, oxygen by the mouth. (500 mm. is about equal to 70 per cent. oxygen in alveolar air.)

CHART 2.

\* Receiving a grant from the Medical Research Council.

comfortable if the hole points downwards. The distance from the exterior to the nasopharynx is about three inches. The catheter can be conveniently fixed to the cheek by a piece of sticking-plaster. Prolonged personal use shows that passing the gas through warmed water lessens the discomfort; it also has the advantage of making the flow of gas visible. A flow meter is convenient, but not essential. The flow should be as fast as the patient will readily tolerate. A reducing valve or some sort of fine adjustment is most desirable, but in any case the catheter should be disconnected during any manipulation of the taps. Care should be taken to keep the tube leading to the patient free from water.

#### A New Modification.

As might be expected from the superiority of the face-mask over the catheter in raising the alveolar oxygen, it has also been observed clinically that the former method may remove entirely a cyanosis which the latter had only been able to lessen. Consideration of this, and of the drawbacks of the face-mask mentioned above, has led to the trial of a mouth-mask which allows the patient to breathe oxygen by the mouth while leaving the nose free to breathe air. It appears to be more comfortable and more willingly borne by the patient. The front is covered by a large flap of thin rubber, which gives a minimal resistance to expiration. The tube connecting the oxygen bag comes in underneath. The mouthpiece is provided with an inflated rubber cushion to make it fit comfortably; it is held in place by a piece of elastic which passes behind the head. Oxygen is breathed from a bag in which the gas collects during expiration, as described by Haldane. Gilchrist and Davies<sup>1</sup> have described a 'modification of this principle, which is simple to make and highly efficient in use.\* Chart 2 shows the effect on the alveolar oxygen; the highest figures are obtained if the nostrils are lightly plugged with cotton-wool. By this means in another subject the average alveolar oxygen was 650 mm.; but it is not considered advisable to maintain such high pressures indefinitely, since there is experimental evidence that pure oxygen for three days causes pulmonary oedema in certain animals.<sup>12 13</sup> Further work is in progress on the clinical use of this apparatus and the effect it has on the oxygen in the arterial blood.

## INTUSSUSCEPTION IN AN ADULT DUE TO A POLYP OF MECKEL'S DIVERTICULUM.

BY

IAN MACDONALD, M.D.,

HUELVA, SPAIN.

A CRITICAL study<sup>1</sup> of intussusception in the adult shows that in 36 per cent. of the cases an intestinal tumour is the predisposing cause. The tumours in order of frequency are: simple polyps, lipomata, fibromyomata, and adenomata; malignant growths rarely occur in this type of intestinal obstruction. In the following case the intussusception was caused by a pediculated polyp which arose from a Meckel's diverticulum.

A man, aged 40, who had previously enjoyed excellent health, complained of slight discomfort round the navel and in the right iliac fossa. He, however, continued to eat, work, and live his ordinary daily life, and his bowels at this time acted normally.

\* Both this and the mouth-mask are obtainable from Siebe Gorman, Westminster Bridge Road.

Four days later, after his evening meal, he was attacked by severe abdominal pain, accompanied by vomiting, which had continued, in spite of all treatment, for ten days, when he was admitted to hospital. The vomited matter had been first food, then bile, and latterly it had developed a faecal odour. During these ten days the bowels, in spite of purges and enemata, were absolutely constipated. On admission the vomiting had ceased for twelve hours, but the pain continued, the pulse was 80, and the abdomen was distended, but not tense. Peristaltic waves were clearly visible, running transversely in the "ladder pattern." The hernial sites and the rectum were negative and no tumour could be felt in the abdomen.

About six hours after admission the abdomen was opened incisionally below the navel, under morphine, intravenous sodium, and intermittent ether anaesthesia. Coils of very dilated small bowel bulged into the wound, while the caecum was brought out with a little difficulty. To its inner side twisted coils of small intestine could only be partly unraveled, and further examination revealed a hard mass in the interior of the caecum. It now became obvious that an ileo-caecal intussusception had occurred, so the intracaeal mass was gently pushed out through the ileo-caecal valve and the intussusception rapidly reduced. On continuing to push the tumour further along towards more healthy bowel it was suddenly arrested about two feet from the caecum, its pedicle of attachment arising from the inner aspect of a broadish Meckel's diverticulum about the size of the last joint of the thumb. The diverticulum was of a blackish-purple hue; the proximal ileum was intensely congested and much distended, while the distal portion was narrowed.

Resection of the parts was decided on, so the bowel was divided fully six inches proximal, and about three inches distal, to the pedicle of the tumour. After careful haemostasis of the sordid mesentery the intestinal ends were rapidly closed by a purse-string suture over a Parker-Moynihan clamp, and lateral anastomosis was performed. Finally an enterostomy was performed about eight inches proximal to the anastomosis on the dilated loop, a small tube being rapidly fixed in the bowel by a couple of purse-string sutures. The intestine was then fixed by a single catgut stitch to the peritoneum of the wound; the abdomen was closed and the patient put back to bed in good condition. He slept tranquilly all night; the pulse never exceeded 100, and there was no vomiting. The ileostomy tube drained very freely for forty-eight hours; and the bowels moved naturally on the third day; the tube became loose on the fifth day, and the patient left the clinic a month after his operation, with the wound soundly healed.

In this case, since the intussusception was reducible, the question arises whether excision of the diverticulum, extraction of the polyp, and transverse suture of the bowel might not have sufficed. A table of statistics, however, in Guoulette's thesis<sup>2</sup> shows that in 104 cases resection was performed 60 times with 41 recoveries. In intestinal obstruction after the obstacle is removed experience leads to the belief that enterostomy on the distended proximal loop is an important factor in the successful issue.

The specimen, placed by Professor D. P. D. Wilkie in the museum of the surgical department, Edinburgh University, is a thick polyp about three inches long, springing from the inner surface of a flattish Meckel's diverticulum. Histological examination showed that the intestinal polyp consisted of fibrous tissue into which haemorrhage had taken place. There was no evidence of malignancy.

## BLASTOMYCOSIS OF EYE AND FACE SECONDARY TO LUNG INFECTION.

BY

ARNOLD S. FERGUSON, F.R.C.S.Ed.,

AURAL AND OPHTHALMIC SURGEON, JERSEY GENERAL HOSPITAL.

FUNGUS involvement of the lungs, according to the statistics of Colonel Marett, medical officer of health and States bacteriologist, is of frequent occurrence in Jersey. The following case is of great interest, as the eye and face conditions are definitely secondary to the lung infection.

A man, aged 58, was sent to me by Dr. Sydney Whitaker. The patient was very evidently ill and emaciated. There was slight sclero-keratitis with accompanying ciliary injection of the left eye. Within a week the limbal conjunctiva and episcleral tissue showed

a raised violaceous thickening, and a ring of large granulomata formed a corona around the cornea. At the same time a large beefy-looking growth appeared on the right cheek. This was excised by a consulting surgeon, but by the time the stitches were ready for removal there was a recurrence spreading up to the right lower lid, and another growth appeared on the nose, over the left ala and tip.

I made a tentative diagnosis of tubercle, in spite of the rapidity of invasion, and the report of a well-known pathologist to whom a section of the growth had been sent seemed to confirm this.

FIG. 1.—Case of blastomycosis. Nose infection.

FIG. 2.—Blastomycosis. Right cheek infection.

The eye condition began to look desperate, and I saw the patient with Colonel Marett, who suggested examination of the sputum: he reported blastomycosis, and recommended a method of treatment which was carried out by Dr. Whitaker with the most happy result. The granulomata and ugly violaceous thickening have disappeared from the eye, the growths on cheek and nose have also vanished, and the patient has increased 9 lb. in weight in five weeks.

In view of the interest of this case, seeing that, apart from his grave general appearance, treatment of his eye for tubercle would have been hopeless, and that the other eye was being menaced by the rapidly advancing growth on his right cheek, I have appended Colonel Marett's notes.

#### NOTES BY COLONEL MARETT.

The patient was brought to see me by Mr. Ferguson. The condition as seen then (April 19th) showed infection of left eye, nose, and right cheek. On inquiry he was found to be suffering from cough, with sputum, and loss of weight. A section of the growth from the cheek had been examined by a pathologist. There was rapid recurrence after removal. Examination of the sputum showed the infection to be monilia, and the method of infection of the skin was undoubtedly due to the use of handkerchiefs infected from sputum.

The treatment recommended was increasing doses of potassium iodide up to 30 grains three daily, and weekly increasing doses of monilin vaccine, the parts to be painted with a solution of 0.5 per cent. each of brilliant green and crystal violet to combat sepsis, and the patient advised to use paper handkerchiefs. It is interesting to note that the report of a section stated that the condition was due to tubercle. Skin infection with monilia is known, and is less frequent than moniliasis of lungs, no case of double infection of lung and skin having been recorded according to the literature available, but owing to the fact that monilia skin infections are usually on the face, it is quite possible that these infections may be secondary to a lung infection. In Jersey the frequency of monilia of the lung is as common as tuberculosis of the lungs, and most of these latter suffer from the double infection. *In vitro* it has been found that there is a symbiotic action between tubercle and monilia. Tubercle grows readily in an alkaline medium, whilst monilia require an acid medium. All cases of true double infection do best by having monilia treated first, and then proceeding with tubercle vaccine. It must be understood that it was solely a monilia infection in this case, and at the time of making the diagnosis a good prognosis was given.

#### TWO CASES OF MULTIPLE URETHRAL CALCULI.

##### I.

The following case, in which retention of urine was caused by the presence of a very large number of urethral calculi, seems to be worthy of record.

A Chinese coolie, aged 45, was admitted to the Ipoh District Hospital, Federated Malay States, suffering from retention of urine. He had previously had no trouble in passing urine, and there was no history of venereal disease. On physical examination a large hard smooth mass was easily palpable in the penile urethra anterior to the scrotum. Further back a large sac was found, which proved to be the enormously dilated urethra; when handled it rattled, and a very great number of stones could be felt.

An incision was made over the most anterior and largest stone, and the urethra was opened. No fewer than 120 phosphatic calculi were then extracted with a slender curved forceps. A sound was passed into the bladder, but no further stones were found. The urethral incision was closed and the patient made an uneventful recovery. Cystoscopic examination at the end of convalescence demonstrated a perfectly normal bladder free from stones.

Perak, Federated Malay States.

##### II.

The case recorded below, in which close on a hundred stones were removed from the urethra of the patient, presents several interesting features.

A Chinese boy, aged 9, was brought to the hospital of the Shantung Christian University with a history of painful and difficult micturition for three years. The child looked ill, and was badly nourished.

A large stony-hard lump was felt in the posterior part of the penile urethra. On making a rectal examination what appeared to be another hard, rounded mass could be felt in the position of the bladder. It was not possible to pass a catheter, since on entering the urethra it almost immediately impinged on the mass mentioned, and it was quite evident that this was a stone impacted in the posterior urethra. A diagnosis of stone in the bladder with another in the urethra was made. The bladder was distended up to the umbilicus, and the kidney function was very poor, as shown by the urea concentration test.

In order to improve the child's condition with a view to operation he was given syrup freely by the mouth and 20 grains of sodium bicarbonate in water every two hours for one day. In the

evening he was given 33 oz. (1,000 c.cm.) of a 5 per cent. glucose solution per rectum and a similar dose the following morning. The operation was performed at 2 p.m.

As it was thought that a suprapubic as well as a perineal incision would have to be made, and as the condition of the patient did not admit of a prolonged operation or anaesthesia, arrangements were made for one of us to operate on the perineum while the other did what was necessary in the suprapubic region. Open ether was administered, and an incision was made in the perineum over the mass, with the result that a number of faceted stones at once came into view and were taken out. In front of these was a larger stone, about the size of a bantam's egg ( $1\frac{1}{2}$  by  $1\frac{1}{4}$  in.), which was firmly impacted in the urethra, its narrow end being directed forwards. When this was removed it was found that there were many more of the smaller faceted variety packed closely together and forming the mass which had been felt per rectum. It soon became clear that a suprapubic incision would not be needed. When all the stones were removed by means of forceps and a scoop it was found there were 93 in all, including the large one; the 92 small ones ranged in size from  $1\frac{1}{2}$  by  $7\frac{1}{16}$  in. to  $1\frac{1}{4}$  by  $3\frac{1}{16}$  in. in size, and were all faceted.

After they were removed the cavity in which they were embedded was explored with the finger and found to be the posterior urethra much dilated. In its roof the internal opening of the urethra could be quite easily detected; through this opening a catheter was passed, and some ten or twelve ounces of urine were drawn off. Though this opening was quite patent and easily admitted the tip of the index finger there was not a single stone in the bladder, the whole of the 93 being jammed closely together into one mass in the prostatic urethra. The bladder was drained for a few days through the perineal wound and the patient made a good recovery, leaving the hospital two weeks after the operation.

#### APPENDICECTOMY DURING HERNIOTOMY UNDER LOCAL ANAESTHESIA.

The following case presented some interesting features, and seems worthy of record.
